Samuel Browne, R.N., whose photograph is shown above, seems to have been a remarkably able man. He was an organiser and a leader and was concerned with the well-being of the societies he was president of, and with the well-being of the profession. He presented many cases to the societies and his descriptions of his major cases are significantly better than most other reports.

BELFAST CLINICAL AND PATHOLOGICAL SOCIETY

SIXTH SESSION

1858–1859.

CONTINUED FROM VOLUME 1

NINTH MEETING.

1st January, 1859.

The PRESIDENT said he would be glad to hear the observations of members on Dr. Murney's cases of injuries of the head.

Dr. M'GEE said the cases reported by Dr. Murney offered several points of interest. The first case he considered singular, for the lateness at which coma set in—49 hours after the fall. He pointed out, as a possible cause of extravasation and consequent coma, the occurrence of laceration of the middle meningeal artery by its own pulsations against the margin of the fissured bone; and he related a case of gun-shot wound in which a similar occurrence took place, and extensive hæmorrhage, followed by friction of the femoral artery against spiculæ of the comminuted femur, six days after the injury.¹

The second case he considered interesting, from the cessation and resumption of the respiration and pulsations, and he ventured a supposition that the heart might have been in a state of fatty degeneration—such condition, according to Dr. Stokes, being a cause of apnœa.

In the third case he considered there had been fracture of the base and rupture of the membranes, and he formed this opinion in consequence of the serous hæmorrhage from the ear.

Professor GORDON said, in the case of the boy, he did not agree with the opinion expressed by Dr. Murney as to the time at which the effusion of blood took place. He thinks that it occurred shortly after the accident, and gradually accumulating, had not attained sufficient magnitude to produce fatal compression until a short time antecedent to death. He looked upon this case as having a very important practical bearing on the treatment of severe injuries of the head. It points very distinctly to the injurious consequences that might result from the early exhibition of stimuli; for, if the amount of injury the intra-

cranial mass be such as likely to lead to the extinction of life, the early exhibition of stimuli will not prevent a fatal result, but in cases in which recovery from the collapse supervenes they will rouse prematurely vascular action, and determine to hæmorrhage. It is, therefore, our duty to prolong the collapse rather than to shorten it. A turpentine enema at such a time will do good. As to the use of the stomach pump, he could not comprehend the principle which would justify its use. The introduction and pressure of the tube in the œsophagus would unquestionably induce spasm of the glottis, and, as a consequence, venous congestion in the right side of the heart, in the veins of the neck and head, and determine to hæmorrhage. He, therefore, regarded the use of the stomach pump as decidedly injurious, entailing much more serious consequences than any that might result from the contents of the stomach. In forming a diagnosis and prognosis in severe injuries of the head, the vital symptoms are generally vague and unsatisfactory as to the real nature and extent of the intra-cranial lesions. The physical conformation of the cranium, and forces acting on it, have been too much overlooked. Thus, when a man falls from a height and alights on the upper part of the head, the vertex is depressed and approximated to the base, whilst the lower borders of the parietal bones are thrown outwards, frequently detaching the squamous from the petrous portion of the temporal bone. When a person falls in this manner, and *from no great elevation*, from the force and conformation of the skull we may naturally expect fracture of the temporal bone, and its consequences—effusion of blood between the dura mater and anterior inferior angle of the parietal bones from rupture of the middle meningeal artery; also hæmorrhage from the ear, frequently from laceration of the lateral sinus, and also welling of a clear fluid from the ear, mixed or un-mixed with blood, from the sac of the arachnoid being opened. Effusion of blood from the ear has been regarded as indicative of a fracture of the base of the skull, but to give to it its true signification, it is only a strong presumptive evidence of a fracture of that part of the base of the cranium corresponding to the juncture of the squamous and petrous portions of the temporal bone. This is true as regards the generality of such cases, but rare instances have occurred in which there was in some cases hæmorrhage, in others welling of clear fluid, without fracture. Let us carry our reasoning a little further; let us suppose that the height of the fall has been considerable, and the man weighty. The violence will, therefore, be greater, and we must expect more extensive injuries; fractures of the vertex, disjunction of the sutures, fracture of the basilar process, and fractures radiating from the condyles, taking different directions, according to the relative strength of the several parts of the cranium. Dr. Gordon, therefore,

¹ [When this report was published in the *Dublin Hospital Gazette*, the Editor added:—"We are cognizant of a case in which a similar occurrence took place. A gentleman was riding about four miles from town, when his horse fell, but not seeming to be much hurt, he remounted and rode home. When near home, he observed the horse to be gradually becoming weaker, and at last to stagger under him. He had barely time to leap off, push the animal from him, when it dropped dead. *Post-mortem* examination showed that at the time of the first fall the animal had fractured a rib, and that the aorta, pulsating against the point of fracture, had gradually torn itself, and that a sudden burst of hæmorrhage had proved fatal."]

infers that if Dr. Murney had taken these various circumstances into consideration, he might have anticipated the extensive injuries met with in one of his cases. The man falls from a considerable height upon a *flagged flooring*, alighting upon the upper part of the right parietal bone. The vertex thus first reaches the flags, the whole weight of the body impinges upon the condyles, and comminutes the base. From the very nature of the forces brought into operation, so are we to expect fractures. Hence valuable information may be gained as to the diagnosis and prognosis from the physical conformation of the cranium, and from the forces acting on that structure. In blows and falls upon the head, the most frequent seat of separation of the dura mater from the skull is unquestionably at the anterior inferior angle of the parietal bone, and the reason of this is, that the connexions of the dura mater, especially the tentorium, does not permit this membrane to follow the sides of the cranium, when thrown outwards by force acting on the vertex. As regards the treatment of injuries of the brain, Dr. Gordon expressed himself as opposed to exhibition of mercury pushed to salivation. He says that injuries of the brain depress vital energies and the reparative process, and determine to unhealthy action in the part of the brain injured. A person who is under the influence of mercury is not in a fit state to undergo a surgical operation, as unhealthy inflammation is almost certain to attack the wound. He, therefore, recommended the head and shoulders to be well elevated, cold applied to the head, and a mild but continuous action to be kept up in the bowels, by the exhibition of the neutral salts, so that the patient may have at least three or four motions daily, at distant intervals. He does not object to the exhibition of mercury as a purgative, for he looks upon it as a most valuable remedy for the removal of mucous secretions and other unhealthy matters from the intestinal canal.

Dr. Ross wished to ask Dr. Murney if in his first case, he had observed layers in the clot effused from the lacerated meningeal artery, as such a constitution of the clot would show that the effusion had not taken place suddenly.

The PRESIDENT said that while he fully concurred in several of the remarks of Professor Gordon, he must dissent from one or two of his propositions. In the first place, as to the non-exhibition of stimuli in bad injuries, under any circumstances, he could not agree, as he had seen several cases of concussion in which life seemed hanging in the balance, and when both alcoholic and diffusible stimuli had been given with the happiest results. In fact, he felt certain that such cases would have succumbed had stimuli been withheld. He also could not subscribe to the Professor's doctrines regarding mercury in the cases under consideration; he had seen many cases of very severe injury of the head, where the grave symptoms

were at once relieved when the patient came under the influence of that most valuable drug, and one of the cases reported by Dr. Murney fully illustrated this. In conclusion, he felt it his duty to express the pleasure he had experienced in listening to Dr. Murney's lucid and able paper, and the interesting discussion which it had elicited; both were exceedingly valuable in a practical point of view.

Dr. MURNEY said—Observations have been made on the cases I have brought before the Society, by Dr. M'Gee, Professor Gordon, Dr. Ross, and the President. As the last-named gentleman has addressed himself to the remarks of those who immediately preceded him, I do not consider I am called upon to do more than express my concurrence generally with the opinions he has just stated. If I mistake not, Dr. Ross asks, "Was the clot, formed in the first of my cases, carefully observed, to note if it had all been poured out at the same period, or if there were any lamellæ of fibrine to indicate a series of extravasations," as appearances of this character had fully warranted the opinion of a number of hæmorrhages in a case which had been examined by him. In reply, I beg to say, not anticipating a clot of the magnitude I described, I examined it with the utmost care, and am perfectly satisfied all the blood was poured out in a very few hours.

Professor Gordon has stated—

1st. He considers the tentorium cerebelli officiates as a "beam" to hold the lateral portions of the dura mater in their places, and in case of violence from above, that portion of the membrane in which the arteria meningeal media is placed, will be stretched or torn according to the amount of force.

2nd. He considers too little attention is devoted to the mechanism of the head, and seems to think if I had studied that subject more carefully, I would not express surprise at the direction of the fracture in one case.

3rd. He most emphatically disapproves of my having administered stimulants in one case, as he believes such are always inadmissible in injuries of head.

4th. He objects to my having used the stomach pump in one case.

5th. He disapproves of the use of any mercurial preparation, with the object of producing the constitutional effects of that drug.

1st. The arteria meningeal media is placed on a plane anterior, and the tentorium is posterior to the petrous bone. To no part of the base of the skull is the dura mater more intimately adherent than the upper and anterior surface of the petrous portion of the temporal bone; for a strain applied to the tentorium to influence in any degree that part in which the trunk of the meningeal vessel lies, would require the membrane to be separated from the bony surface to which it is so intimately attached, and as I cannot

think of any force which would produce this result, I consider the first statement is not correct.

2nd. I believe no surgeon can form a proper estimate of injuries of the head unless he has studied the mechanism of the skull. If Dr. Gordon will again refer to my cases and observations he will find to my fourth case the following—"I would have been slow to expect a fracture taking the direction I point out. I have not seen any example of it before, and, judging from the strength of the parts involved, I am sure it must be very rare." I confidently repeat this expression of opinion, and am satisfied fracture in this direction must be very infrequent.

3rd. I think no surgeon can be more strenuously opposed to the indiscriminate administration of stimulants than I am. I consider it my duty, however, to protest against the sweeping rule as laid down by the Professor. I believe stimulants are not only admissible, but absolutely necessary in those most serious cases of head injury in which the collapse is extreme, and the very life of the individual is hovering in the balance. In milder cases, experience teaches us excitants are absolutely prejudicial.

4th. Reference to the case in which the stomach-pump was used, will, I consider, readily explain my reason for applying it. The man was intoxicated when he received the injury, and I believed it was most desirable to remove, if possible, any whiskey or other drink. Nothing was found in the stomach. Most probably as the patient had not partaken of dinner, absorption from the digestive cavity occurred with considerable rapidity. Upon this subject I have not heard any argument to change my view, and indeed cannot understand how, if stimulants are at all times inadmissible, there can be such serious objection to the use of the stomach pump in cases such as mine.

5th. I do not this moment recollect any exception to the rule that some of the preparations of mercury should be used in *all* cases of injury of the head—in the milder forms, as purgative, alterative, or both—in the more serious, with the design of producing the full constitutional effects. We all know that, with the exception of some head cases, general bleeding is now rarely practised by surgeons, and in no class of cases are we more imperatively called upon to pursue antiphlogistic treatment and regimen than in those under consideration. Now, mercury is an admirable antiphlogistic, and, therefore, do I use it. In addition, I believe it is impossible to say, in any given instance, we have an unmixed case of concussion or compression, and as mercurial preparations are pre-eminently useful in promoting the action of the absorbents, and thereby facilitating the removal of deposited blood, lymph, we have a second and most cogent argument for its administration.

Dr. M'Gee asks, at what period I calculated the fatal hæmorrhage in the head had commenced in the

first case. I think I have given an explanation most in accordance with the circumstances. I made careful inquiry to know if the patient had made any exertion—as getting up from bed, urination, defecation—prior to the stupor which preceded death, but I was unable to obtain satisfactory information. I believe a clot was formed in the lacerated artery at the time of the accident. From some cause this was dislodged within five hours of his death, and bleeding, of course, ensued. I cannot answer Dr. M'Gee's second query, as to the condition of the muscular fibres of the heart in my second case, as I was not permitted an opportunity of examining the thoracic, or abdominal contents.

{Rough minute book: Dr. M'Gee made a speech moving that all legally qualified physicians and surgeons be members.

Dr. Maconchy was elected unanimously.}

Council Ordinary Meeting January 5th 1859.

President, Dr. Murney, Dr. Heeney, Dr. Wales, Dr. Cuming.

Form of notice of election ordered to be printed.

Circular prepared.

TENTH MEETING.

8th January, 1859.

Mr. Johnston exhibited some fine specimens of *tubular lymph casts* of trunks of the bronchial tubes with their ramifications, which had been expectorated by a patient under his care, suffering under a combination of pneumonia and bronchitis. He read the case as follows:—

Ellen Harrison, aged 15 years, slender figure, pale, anæmic appearance, and nervous temperament, became unwell on Sunday, December 12th, being seized with rigor, sickness of stomach, loss of appetite, and stitch in right side. On Monday, 13th, she was feverish, and had a teasing cough. Tuesday and Wednesday, in addition to the symptoms mentioned, her expectoration was rust-coloured. I visited her on Wednesday evening, fourth day of her illness, and on examination found the usual physical signs of pneumonia of the right lung, passing into the second stage; the greater portion of posterior surface of the organ was engaged. The physical signs were *dulness*, where crepitus was passing in to bronchial respiration, *rusty sputa*, and *difficult breathing*. There was a considerable amount of bronchitis of left lung and anterior portion of right. This might in part explain the great difficulty of breathing present, which was out of proportion to the extent of the pneumonia. In all its characters the case bore a very urgent aspect. I ordered powders, with one grain of calomel, two grains of grey powder, and three grains of Dover's, every

second hour. On Friday, 17th, thirty-six hours after the first exhibition of the mercury, there was evidence of its action on the system, and at the same time an immediate improvement in the symptoms. On this day and Saturday, coincident with the action of the mercury, there occurred what I regarded as a feature of interest in the case, viz., the expectoration of lymph membranous casts of the bronchial tubes, and their ramifications, similar in character, I presume, to those occasionally thrown off from the trachea in cases of croup; I have not known, however, of such membranous excretions being of usual occurrence in cases of pneumonia. You have here one or two specimens. Upon examination you will find these hollow; indeed, shortly after being thrown off we were able to inflate them, so as to represent a bronchial tube of the second or third order, with its minute divisions. I need not follow up the details of the case.

She continued to improve from this date, and when I saw her on Thursday, she was sitting up, her chief complaint being in regard to her mouth. We must attribute the rapid and favourable progress of this case to the salutary action of the mercury, one scruple of calomel and less than one drachm of grey powder was the entire amount given. She was neither blistered nor bled. I mention these facts, as I consider it is instructive as well as satisfactory to point to the unaided and salutary action of such a small amount of mercury.

Are we to regard these cylinders of membrane as identical with the false membranes thrown off from inflamed serous membranes; and as, therefore, affording us an example of adhesive inflammation in a mucous membrane? We know that such an event of inflammation does take place in early life, but I believe it is rare after puberty, so far at least as regards the pulmonary mucous membrane. I was led to consider the casts as emanating from the pneumonic part of the lung, from the fact of the bronchitis not being intense, and from the improvement in the lung affected by pneumonia being coincident with the expectoration of the casts.

Watson, in his last editions, points out two points of distinction between such membranous excretions and those false membranes that are formed on serous membranes, viz., that such an example as I here present is more of an *albuminous* nature, brittle, and less fibrous; and secondly, that it is not *plastic*; that is, that it never becomes organized, never connects itself with the surface from which it proceeds, but, as in this case, becomes detached, and if the patient progress favourably, is thrown off. The last point that crossed my mind in reference to this case is, whether, with the occurrence of such membranous excretions in a case of pneumonia, we have any more need to fear the supervention of phthisis, than in ordinary cases of pulmonic inflammation.

Professor FERGUSON said he wished to ask Mr. Johnston the physical signs of pneumonia present in this case, and their extent.

Mr. JOHNSTON said the physical signs were dulness, where crepitus was passing into bronchial respiration, rusty sputa, and difficult breathing.

Professor FERGUSON next enquired whether Mr. Johnston considered the casts the product of pneumonia or bronchitis.

Mr. JOHNSTON said he believed they were thrown off from the tubes penetrating that portion of the lung affected by pneumonia.

Professor FERGUSON said that, at the present time, the pathological indications of such formations deserved special attention. He adverted to the probability of the tube casts being the result of a diphtheritic state of the bronchial lining, rather than of pneumonia; and also to a case brought under the notice of this Society, in which similar formations were expectorated by a person in health (a cast of which he exhibited.) He further said, that he was not aware of such casts accompanying pneumonia, though not uncommon in bronchial and catarrhal affections.

Professor REID said that such casts had occurred in pneumonia as well as in bronchitis, and according to Stokes, they had been thrown off more frequently by the aged than by the young. In the case before the meeting he considered it difficult to say from what part the casts came—whether from the pneumonic or bronchitic part of the lungs.

Dr. PATTERSON said the substance of the casts under notice very much resembled that of exudations from the fauces in a case of diphtheria under his care.

Dr. ROSS said the casts, in his opinion, indicated inflammation of an active character. He expressed surprise at Dr. Reid's statement as to the more common appearance of such formations in the old than in the young.

Professor REID said that statistics bore out his statement.

Professor FERGUSON remarked the disproportion between the dyspnoea and the extent of pneumonia in Mr. Johnston's case. He asked if the former was not relieved by the expectoration of the bronchial casts, and he said he did not think the exudations the result of pneumonia.

Dr. HEENEY said he considered the relief to the dyspnoea in this case due to the expectoration of the casts, and its previous existence chiefly to their presence in the bronchial tubes.

The PRESIDENT said he believed such formations may result from asthenic as well as acute action. In cases of diphtherite he had seen patches of exudation, but no tube casts like those under notice of the Society.

Mr. JOHNSTON said he was quite alive to the importance of considering the prevailing type of dis-

ease, in coming to conclusions as to the nature of his case. He had recently had exudations on the pharynx in cases of typhus and hydrocephalus. In the case before the Society he was led to consider the casts as emanating from the pneumonic part of lung, from the fact of the bronchitis not being intense, and from the improvement in the lung affected by pneumonia being coincident with the expectoration of the casts.

Professor FERGUSON wished Mr. Johnston to explain how crepitus could be heard in the pneumonic lung, if the trunks leading to the smaller tubes and air cells had been obstructed by casts, such as these exhibited.

Mr. JOHNSTON observed that a similar difficulty would stand in the way of the Professor explaining the presence of bronchial rales in the bronchitic part, supposing that to be site of the exudations.

Dr. M'GEE said that Professor Ferguson's objection could not weigh, as the tube casts were tubular, and therefore pervious to air.

Professor FERGUSON said that the object of his remarks was to ventilate the subject thoroughly, and he had succeeded.

Case of Abscesses in the Brain, by Dr. Harkin.

Robert Elliot, aged 35, unmarried, of temperate habits, and recently returned from America, called on me upon the morning of Thursday, 23rd December last, complaining of intense headache, debility, and pain of the back. He had never been subject to headache or any cerebral affection in his youth, but about fifteen years since had a severe attack of hæmoptysis, and more recently suffered from three prolonged attacks of "fever and ague." Since his return from the United States, in October last, his friends state that he had become irritable in temper, lost his accustomed cheerfulness, and avoided all society. It was not, however, until the 14th December that he exhibited any symptoms of illness, when, after taking saline medicine to relieve some uneasiness in the stomach and bowels, he was seized with a rigor which continued for three-quarters of an hour, followed by a hot fit and by vomiting.

On the 15th and 16th he complained of violent pain in the back, extending along the greater part of the spinal column; about the 17th it extended to the loins, the groin, and the lower part of the abdomen; at this time his urine was found to be loaded with lithic acid deposits, and the chamber utensil stained as if with red paint. He continued in this state till the 20th, becoming very restless at night, when he first discovered weakness and loss of power in his right arm; on the 21st it became completely paralyzed. He remained in this condition, still taking food, and his bowels acting, after mild purgatives, till 23rd, when, becoming alarmed at his state, he called on me. I advised him immediately to return home and lie

down, and saw him soon after in his bed, when he presented the following symptoms:—His principal complaint was of intense pain of a dull throbbing kind, which extended all over the head from the forehead to the occiput, constantly present, but aggravated at intervals, and at night becoming unendurable. He was very giddy when he attempted to stand, and his pulse was about 100 in the erect position, lower when in bed, very small and compressible. The forehead and temples hot; the eyes natural; the pupils obeyed the stimulus of light, but slowly, especially the left. His tongue dry and brown; sense of hearing unimpaired; speech occasionally indistinct; had also transient fits of incoherence. The right arm was completely paralyzed, and a little colder than the other; the fourth and fifth finger bent; no other sign of contraction; no lesion of sensation in the arm. The application of leeches to the temples, cold lotion to the forehead, occiput to be shaved, and a blister to the back of the head and neck were then ordered. He had also ten grains of calomel administered, to be followed by two grains every alternate hour, and warm applications to the feet. The leeches were applied, and procured an interval of ease for about three hours; he, however, peremptorily refused to permit the application of the blister. He passed the night of the 23rd in a very excited state, having dressed and undressed himself three times. His sufferings were intense and his screams very loud. Finding on the 24th that he still persisted in refusing to have the blister applied, and that his friends had lost all moral control over him, I recommended his removal to the General Hospital, whither he was taken same evening. From the first moment I had seen the man, it was quite evident disorganization of the brain had set in; that the inflammatory period had gone by, and with it the time for active treatment and hopeful interference, and that in the presence of abscess or softening of the brain, medicine had no effectual remedy.

Dr. W. MacCORMAC, in continuation of Mr. Harkin's case, said the man was admitted to the General Hospital, on the 24th December last. He complained of headache and motor paralysis of right arm. Pulse normal, vision and hearing perfect. On the 25th he was worse, the pain in the head occurred in violent paroxysms, and mercurial fœtor set in. On the 26th the pain was still worse. No sickness. Suspicions of the pain being of a neuralgic character were entertained at this time. On the 27th the pulse was slow and irregular. The pupils, one natural, the other dilated. The right leg became paralyzed. He complained of ringing noise in the left ear, and remained sensible till the 2nd of January, when he died.

The *post-mortem* examination was made by Dr. Murney, on Sunday last. On removing the dura mater, he found pus on it. He exhibited the brain, and demonstrated its condition to the Society as follows:

—An abscess in the anterior part of the right hemisphere; another in the same part of the left; one in the left lobe of the cerebellum; together with several smaller abscesses in the upper part of both cerebral hemispheres, but none whatever in the base of the brain. He adverted to Rokitansky's observation on the rarity of circumscribed abscess of the brain, and said the present case afforded well-marked illustrations of such.

Dr. M'GEE said the impairment of hearing on one side, and the loss of motive power on the other, were points of interest in the case.

Dr. ROSS said the large abscess in the left cerebral hemisphere might have been primary—the other abscesses resulting from it by absorption. He said the supervention of loss of power on the right side bore out that view somewhat.

Mr. HARKIN said he believed rigors had only occurred once.

Dr. MOORE exhibited a left testis greatly enlarged by medullary disease (of which it was a good specimen), which he had removed ten days previously from a man aged 42. The disease commenced about 12 months since, and originated in a hurt. The symptoms were those of hydrocele, and a practitioner, supposing it to be such, had tapped the part, but only blood flowed. After this the tumour became painful and rapidly increased. The spermatic cord was, however, free. The wound healed by the first intention, and the man was able to leave hospital in a week.

The President said his experience of such cases made him fear the disease would return.

Council Ordinary Meeting January 12th 1859.

President, Drs. Dill, Bryce, & Cumming.

Circular prepared.

ELEVENTH MEETING.

15th January, 1859

The PRESIDENT exhibited the recent parts after amputation, and made the following observations.—

Case of Resection of the Knee-joint.

The subject of the following brief remarks is a man aged 27 years, named Samuel Goudy, a painter by trade, and a native of Belfast. He is of phlegmatic temperament, and of the strumous diathesis. Some seven years since he first came under my notice, with the usual symptoms of inflammation of the right knee-joint, as seen in a person of scrofulous habit. From time to time these inflammatory attacks were subdued, recurring, however, from very slight exciting causes, the joint remaining stiff and swollen, but without pain, in the intervals. This state of things continued up till the period of his last admission into

hospital, in July, 1858. He then complained of pain on any attempt at motion, and on pressure over the patella and condyles of femur, especially the inner. The parts were infiltrated and considerably swollen, giving the knee all the appearance of a joint suffering from pulpy degeneration; and the severe pain on motion pointed out the probability that erosion or ulceration of the cartilages had taken place. His general health was deranged, the vital functions much depressed, and his total aspect demonstrated bodily suffering and imperfect nutrition. The treatment adopted was with the view of improving the health, and it did improve for some time, when confinement and hospital air began to tell against the system, and it was determined, in consultation, to remove the diseased part; and I wished to give the patient the chance of a good limb, by performing excision of the knee-joint. This operation of resection I performed, accordingly, on the 25th of August. The patient having been brought fully under the influence of chloroform, I made an incision four inches on either side of the joint, *well back*, and united these by a cross-section through the soft parts and the *ligamentum patella*, so as to open the joint. The flap thus formed was turned up, the ligaments were divided, and the ends of the bones exposed, and freed from the soft parts, and were sawn off. An inch and half of the femur, and about three-fourths of an inch of tibia, were removed, and the face of the patella was likewise removed, by means of a metacarpal saw. Upon attempting to bring the cut bones into opposition, it was found requisite, in consequence of the contraction the joint had assumed, to saw off another thin slice from the femur. The limb was then put up on a modification of Mr. Butcher's splint. Some hours afterwards these bleeding vessels were tied, five points of suture introduced into the flap and opposing parts, and the wound was dressed with strips of wet lint. The shock after the operation was trifling, the reaction not at all great, and everything promised well. The wound was dressed first on the fifth day, and every second day afterwards. In a week the cross section had healed, and the wounds looked well, a healthy suppuration having been established.

Up till November everything seemed prosperous, save that I experienced considerable difficulty in retaining the parts in situ, more especially as the patient was impatient of restraint, and his skin became abraded by the necessary bandages. For some ten days I had to allow the limb to be removed from the apparatus, and after the re-adjustment suppuration set in very copiously, the patient's health suffering from the drain. Every means likely to improve matters were resorted to, but beyond the constitutional improvement, no advance was made towards cure. Under these circumstances, I most unwillingly resorted to amputation, which I performed on the 8th

instant, by the rectangular flaps, as recommended by Mr. Teale, of Leeds, and sawed the femur through, a little above the middle part, having been obliged to go so high, in consequence of the sinuses of the soft parts above the knee. I put the flaps together with a few points of suture, and a very few narrow strips of adhesive plaster, and did not disturb the stump till the eighth day. I then removed the points of suture and strips, and the ligatures, save that on the femoral artery, and found adhesion had taken place, without any tendency to suppuration; and the case bids fair to progress to a satisfactory termination, as regards the patient's life.

In conclusion, I beg to offer one or two observations—first, as to the state of parts at the time of the resection. The soft parts had largely degenerated, and the bones showed erosion and ulceration at several points of their cartilages, the patella alone being free from disease. The end of the femur, when cut through, presented a softened state of its cancellated structure, and on the whole did not look well, though not actually diseased beyond repair. Second, as to the steps of the operation, I feel satisfied that I should have divided the hamstrings by subcutaneous section, and I ought also to have removed the patella. Were I to operate again in a similar case, I think I would proceed differently from that I followed in this instance, or that which has been usually recommended. Dr. Murney, who has kindly made a dissection of the amputated parts, will be able to give a report of what he observed, and also to express his views on the whole case, and also the statistics of resection of the knee-joint.

Dr. MURNEY remarked—This patient was under my care for about a fortnight or three weeks in July of last year. At the 1st August he was transferred to Mr. Browne. When first examined there was evidence of ulceration of the cartilages of the knee, of a chronic character. On consultation it was agreed, in the absence of any acute symptoms, that mercurial strapping, perfect rest, and a course of one of the preparations of mercury gently introduced into the system, should be tried. As in this my colleagues expressed the opinion I entertained myself, I gave the patient the only chance of saving his limb (without operation), by endeavouring to procure ankylosis. In a few days the constitutional effects of mercury were manifested; and after continuing its use as long as was considered necessary, without any beneficial result, it was omitted, and every effort made to improve his general health, preparatory to the operation which has just been described. Altogether he was under the influence of mercury about a fortnight; after that time the management devolved on my successor.

At the examination of the limb, I found fatty degeneration of all the muscular textures in the neighbourhood of the knee. A great number of sinuses

passed in various directions, but some of the principal ran to large exfoliating surfaces on the tibia and femur. The hamstring tendons, which were divided a short time since, were connected by organized lymph, and were being united in the usual fashion.

The patella was connected to the anterior surface of the lower end of the femur by bone. A considerable part of the upper end of the tibia was removed by ulceration. Similar action existed on the femur. On the former bone the fore part, on the latter the posterior portion, was affected. A good deal of new bony tissue was deposited on the femur, so as to spread out or expand that bone to a breadth fully as great as before the removal of the condyles. The opposing ends were coated, except the carious portions, with a velvet-like membrane, of a highly vascular character. The two bones did not form a right line, for fully one-third of the femur was in front of the tibia, so that a glance at the specimen suggested the idea of incomplete luxation of the leg backwards.

This case verifies an anatomical objection which frequently occurred to me when considering the operation of excision of the knee—viz., on making the customary incisions, the ligamentum patellæ is cut, and the action of the vasti-rectus and crureus muscles is unopposed, so that the patella must be drawn upwards, and rest, as in this case, upon the femur only. In this situation it does not in any way strengthen the knee. Now, I consider the transverse incision should be made *above* the patella, cutting through the attachments of the muscles already named, that bone thrown down, its posterior surface cut away, if necessary; and when the operation would be terminated it could be replaced, when it would lie in front of both bones, would become united to both, and of course strengthen materially the parts to be ankylosed.

Some observations have been made as to the results of this operation, contrasted with amputation of the thigh. I find in Mr. Butcher's paper, "On Excision of the Knee-joint," published in the *Dublin Quarterly Journal*, for February, 1855, that since 1850, "31 operations are recorded. Out of this number, 5 have died;" and of these latter, one was carried off by epidemic dysentery; another died of pyæmia, sixteen days after operation; and a third was killed by diarrhœa on the twenty-fourth day. Again, in a second table by the same writer, in February, 1857, we have the statistics of 50 additional cases:—16 cures with useful limbs; 15 recovering; 1 relieved; 1 in a precarious state; 9 died; and 7 required amputation; total, 81 cases, followed by death in 14 instances; and if we add to this list 7 amputations, we have non-success in 21, out of 81 persons subjected to excision.

Dr. MOORE exhibited a diseased knee, the opening of which, exposed ulceration of the cartilages, degen-

eration of the synovial membrane, and a curdy deposition in the joint. He said—

“The subject of this amputation is a man, aged 40, who, four years since, became affected with pain in the knee, which yielded to leeching and ordinary treatment. Three months ago he was admitted to hospital. His knee was swelled and painful, and his system participated in the derangement. Alterative and anodyne medicines, together with rest, speedily improved him. He became able to sustain pressure on the joint, and ultimately to walk, when, of his own accord, he went home to the country. In the course of a month he returned, with the joint in a much worse condition, and all blistered over, by the direction of some country adviser. Examination satisfied me as to the propriety of amputation, which, at the end of three weeks’ preparatory treatment, I performed by antero-posterior *semicircular* incisions, and subsequent *circular* muscular cuts down to the bone. While being put under chloroform, I bandaged the limb upwards from the toes, and the femoral artery being well commanded by thumb pressure, I completed the operation with hæmorrhage not exceeding 3 drachms, which was chiefly venous. The flaps came well together, and were retained by six or eight stitches, and the wound is healing by adhesion.”

Dr. MOORE said his case was not suitable for resection, but anyhow, he was opposed to that operation; and Mr. Browne’s case, he said, did not tend to alter his opinions with regard to it.

Dr. MOORE next exhibited a foot which he had removed by *Syme’s operation*, the patient having since done well. He said—

“The subject of this amputation is a woman, aged 28. She was admitted to hospital with *talipes varus*, the foot much swelled, and a large gangrenous ulcer between the great and adjoining toe, extending upwards on the dorsum of the foot. The whole lower limb up to the groin was swelled nearly twice the size of the other, representing, in fact, in most of its characters, the disease known as *Elephantiasis*. The cellular tissue, however, was the part chiefly engaged. There was no pitting on pressure. Rest and suitable treatment reduced the painful swelling of the foot. The history of this case is this—About 15 years ago the patient received a prick of a thorn on the inner side of the foot, which, producing great pain, caused her to walk on the outer part of her foot. The wound from the thorn not healing, and the pain remaining, obliged her, for relief, to continue to walk on the outer side of her foot, until ultimately *talipes varus* was induced, for which, at her own request, amputation was performed.”

Dr. MOORE next introduced a young man, 22 years of age, with an extensive tumour extending from the

posterior part of the neck to the front of the thyroid cartilage, and from behind the ear close to the clavicle, tilting the ear upon it. It is half as large as his head, with a flat irregular circular ulcer on the front. The general colour of the tumour is of a bluish red. He states that about two years ago, a small tumour formed at the angle of the jaw, which was leeches, rubbed with ointments, leeches again, and poulticed, and so on, till it reached about the size of his fist, when, feeling soft in front, it was opened, and a small quantity of thin watery fluid, with a few curdy flakes, escaped. Since then the tumour has increased rapidly. Dr. Moore looked upon it as a malignant growth, and one that would go on increasing, and involving as it does the important part of the neck, he considered it to be beyond surgical art.

The PRESIDENT remarked that the case of knee disease, presented by Dr. Moore, fully justified its removal. He could not agree with him, however, that it was unsuitable for resection; had it been his, he would have given the patient the chance of saving the limb, which, if preserved, is always better than a wooden pin: Moreover, he could not agree that resection of the knee-joint was to be cast aside because some cases had failed—as fail some must—for the statistics of the operation, as already published, give very great encouragement indeed to surgeons to perform the operation in suitable cases. For his own part, his personal experience, like that of Dr. Moore, was not great regarding this operation, but he felt satisfied that the published statistics were correct, and such as to induce him not to abandon it.

He also said he did not consider the second case related by Dr. Moore one of “*Elephantiasis*” as he had described it. He looked upon the affection before them as one of thickening and infiltration of the subcutaneous tissues, without hypertrophy of the skin at all; therefore, not one of elephantiasis. He had seen the disease in a vast number of instances, both in the West Indies and all over the East. In reply to a query from Professor Ferguson as to the advantage of metallic sutures, he said he approved highly of them, and recommended annealed iron wire, No. 32.

The members generally concurred with Dr. Moore in his view of the nature of the tumour in the neck, and in the hopelessness of surgical interference in the case.

Case of Labour, complicated with accidental Hæmorrhage. By Dr. DILL.

On the 13th ult., at 5 o’clock, a.m., I was sent for to attend in her confinement Mrs. C., aged 37. She was the mother of six children. She had one or two miscarriages, and she believed herself to be about a fortnight from the full period of pregnancy. Before I saw her she had one or two faintish fits; however, on reaching her, she had improved, and labour had com-

menced. She was pale, pulse was under 80, and feeble, and the skin was considerably under the natural temperature. She was under the impression that the membranes had given way, and that the waters were discharged, but an examination satisfied me that this was not the case. The os uteri had dilated to the extent of half-a-crown, and the presentation was natural. The pains were feeble, and the progress of labour slow; however, in about eight hours she was delivered of a dead male child. The placenta was expelled in a few minutes afterwards, and with it a great mass of very dark coagulated blood. The uterus contracted perfectly; the bandage was applied, when a few additional clots came away, dark as before. The stomach, which was very irritable from the first, continued so, with retching and vomiting. Opiates were administered with but very temporary relief.

I found, next morning, that she had some rest through the night, but the sickness continued, and there was considerable pain in the epigastric region. No pain or uneasiness whatever over the uterus; pulse under 80 and feeble; skin dry and very cool, tongue pale, dry, and glossy. A sinapism was applied to the epigastrium. The bowels were opened by means of an aperient and an enema, and the opiate was repeated at bedtime. On the 15th, I found Mrs. C. a little improved; she had had some sleep; the sickness was not so distressing; the pain at the stomach was nearly gone, but had shifted towards the right side. I could not ascertain that she had passed any urine since her confinement, and the renal secretions appeared to be suspended. She had been taking a mixture of mindererus and sweet nitre, and she was now ordered, in addition, half-a-dozen pills, each containing half a grain of opium and three grains of blue pill. She took one of these every three hours, until she had taken the fourth. She had, besides, a blister applied to the side. On the 16th, the pain in side was somewhat relieved, but the sickness continued. She passed some urine, but the quantity was so small, and being mixed with other discharges, it could not be examined. From the first there was occasional giddiness, with indistinctness of vision. In the evening I was sent for in a hurry, when I found her sitting up in bed, the mind wandering, and she was totally blind. The pupils were fixed and dilated, and she appeared as one in amaurosis. Her head was placed upon the pillow, and in a short time she became tranquil, and her sight and mental faculties were restored. The pain had now shifted from the side to the back and loins, to which parts a sinapism was applied, and a mixture containing Rochelle salts and a little sweet nitre, was ordered. An involuntary jerking motion of the muscles had been observed for some time, which was becoming worse.

On the 17th I found the pain in the stomach and side quite gone, but some uneasiness in the back and

sickness continued. On the 18th a very small quantity of urine was secured, and being tested with heat and nitric acid, it was found to be highly albuminous, and continued so under repeated examinations up till the 20th, just eight days after her confinement, when she sank rapidly, and to some unexpectedly, though not to myself.

Although we were not allowed a *post-mortem* examination, which no doubt, would have added greatly to the interest in this case, yet I think we should look upon it as one possessing some features of practical instruction.

1st, The complications of labour with accidental hæmorrhage, at first recognised by the fainting fits, and afterwards corroborated by the large quantity of dark coagulated blood which was discharged with and after the placenta; and 2nd, the giddiness in the head and indistinctness in vision, which were observed from the first, and appeared to be increased when in the erect position, struck me as being naturally chargeable to the loss of blood and weakness, although at a later period these aggravated symptoms, as exhibited in the total blindness and mental wanderings, plainly indicated something worse. 3rd, The suspension of the renal secretion was at first accounted for by the fact that no drink, and indeed nothing, had been retained upon the stomach, and of course did not get into the circulation, and hence no secretion by the kidneys. 4th, As the symptoms became more developed, as seen in the jerking motions of the extremities, the total blindness, state of the mind (though but for a brief period), the albuminous urine, too plainly showed that at least the kidneys were the organs primarily affected, and that we had to deal with as pure a case as is on record of blood-poisoning, and at the same time one of a most intense character—or uræmia, which is the result of albuminuria. 5th, The jerking motion reminded me very vividly of the effects produced when strychnia is introduced into the system. And 6th, that disease of the kidneys should have existed, with such an amount of albumin in the urine, is rare in the puerperal state, unless accompanied by œdema, anasarca, and convulsions, which did not at all exist here, and without one or more of which the case was considerably masked at first; and that the latter symptom did not take place can only be accounted for by the poison expending itself in the eccentric, in place of, as is more usual, the concentric form.

Some unimportant observations on this case brought the proceedings to a close.

Council Ordinary Meeting January 19th 1859.

President in chair. Drs. Murney, Bryce, Wales, & Cum-
ing.

Circular was prepared.

TWELFTH MEETING.
January 22nd, 1859.

Dr. MOORE introduced a lad about 18 years of age, having a large venous cutaneous nævus, about nine inches by seven, on the outer part of the thigh, and scarcely elevated above the surface. About four years ago he was admitted into hospital with an ulcer about the size of a halfpenny on the lower part of the nævus, which healed. He was again admitted about three weeks ago, with another ulcer higher up in the nævus, from which there was a great amount of bloody discharge. The ulcer was large enough to contain half a walnut. It was cleaned out repeatedly, touched with solid caustic, and is now healed. From the toes up to the middle of the thigh the whole limb is surrounded (when in the erect position) with a perfect plexus of enormously distended veins, some of them an inch in diameter, and would be supposed to contain, in their distended state, close upon three pints of blood. If the patient suddenly raise himself from bed and stand up, *Syncope* is induced. Dr. Moore remarked, the wound having healed, there is nothing to be done but judiciously to apply a laced stocking for support.

Queries were put by members to ascertain the duration of the nævus, whether it, and the varicose condition of the limb had come on and progressed simultaneously? and whether or not any tumour or other obstruction to the venous reflux could be discovered above the nævus to explain the cause? In answer to these it was stated that the nævus was congenital, and had but slightly increased; that the enlarged veins were the result of gradual and progressive development; and that the most careful examination had failed to discover any mechanical or other cause for the varicose condition of the limb below the nævus.

Professor GORDON next read the following case:—

“Jane O’Hara, aged 40, admitted into the General Hospital on November 12th, 1846. She says that about eight years ago, a small tumour, not larger than a pea, formed in the left mamma. This tumour remained almost of the same size for three years, when the skin covering it became discoloured, and on its being punctured, fluid resembling jelly escaped. After that the wound healed, but the fluid re-accumulating, a second puncture was made, and a discharge of a like description came away. Since that time the tumour has been frequently opened, always followed by the escape of a fluid of the same clear, gelatinous character. About eight months before her admission into hospital I saw her for the first time. The left mamma was considerably enlarged, but not painful, and there were several cicatrices on its surface.

“On admission into hospital the size of the mamma is somewhat smaller than when I first saw her, the

tumour in the interval having been opened. It is very moveable on the surface of the pectoral muscle; the nipple is perfectly healthy, not in the least degree retracted, but immediately below it there is a fistulous opening leading into the interior of the tumour, and giving exit to a sanious discharge. External to this, the skin is, for a small extent, ulcerated, but otherwise not unhealthy. The remainder of the surface of the mamma is slightly uneven, firm to the feel, but not hard, and presenting depressions and cicatrices, the results of former incisions.

“On the 16th I removed the tumour and mammary gland. On making a transverse incision in the tumour, through the fistulous opening, the appearance presented by the section was that of a ripe peach, but external to this it resembled amber-coloured jelly, traversed by widely separated, but extremely delicate bands of fibro-cellular tissue.

“On the day succeeding the operation, the patient was attacked by unhealthy inflammation in the wound, followed by sloughing of the cellular tissue. Three weeks after this the wound was nearly healed, with great improvement in her complexion and general health. A short time after this she left the hospital, and went to America to join her husband, who had emigrated a few months previously. In 1856, O’Hara called on me. On exposing the front of the chest, there was a large cancerous ulceration 8 inches by 6 over the lower part of sternum and upper part of epigastrium; the edges were hard, everted, and prominent, and immediately around it the skin was firm and discoloured. The cicatrix of the operation was healthy.”

Dr. WALES introduced a boy with an anchylosed condition of the shoulder-joint, and relaxation of the sterno-clavicular ligament, permitting free luxation of the sternal end of the clavicle. Motion in this case (which was curtailed and somewhat painful), produced singular frictional phenomena, the source of which was a matter of some doubt, and gave rise to considerable discussion, some considering the grating due to a supposed partial motion in the shoulder-joint, others to the condition of the sterno-clavicular ligament, and most to the friction of the muscles and bony surfaces about the part. The disease commenced seven years since with pains of a rheumatic or neuralgic character in the shoulder and arm, particularly the latter, and gradually motion became impaired. The boy is of a scrofulous habit.

Some unimportant discussion followed this case, with which the proceedings terminated.

Council Ordinary Meeting January 26th 1859.
President in chair. Drs. Wales, Bryce, & Cuming.
Circular was prepared.

THIRTEENTH MEETING.

29th January, 1859.

Vascular tumour of lip.

Dr. CUMING stated that he had examined a portion of a lip which had been removed by Dr. Babington, of Londonderry.

The diseased structure was entirely composed of an immense number of small dilated blood-vessels, interlacing in areolar tissue. There was no evidence of any malignant growth. The following notes of the case had been furnished by Dr. Babington:—

“The patient stated that some two years since she was sucking a thimble, which adhered so tightly to her upper lip that it had to be filed off; that soon after she experienced an unusual pulsation in the lip, and that it gradually increased in size. When first under treatment the pulsation occupied the whole labium. Injections of per-chloride of iron were tried, and it was hoped successfully, as the swelling became solid and all pulsation ceased. She again came under treatment, the pulsation was at this time limited to the right side of the lip, the other side was cured. “Injections were again tried as before, but without benefit, and as the lip was increasing rather rapidly, it was deemed advisable to remove the whole diseased mass.

“The wound healed by first intention, and the patient suffers no inconvenience.”

Arsenical poisoning by wall-paper.

Dr. WALES read a paper on this subject. He said—

Mr. President, the first notice on the circular of to-day is a “Case of Arsenical Poisoning by Room-Paper.” That case, Sir, I have the honour to bring under the notice of this Society, and I would substitute for the startling announcement the less alarming, though perhaps not less true title, “Supposed Deleterious Effects of Green Flock Paper.” Is bright green flock paper on the walls of our sitting-rooms prejudicial to us? This is a question, Sir, that people are beginning to ask. It has been answered in the affirmative and in the negative by high authorities on the one side, and official authority on the other.

Conceiving it to be the object of our high calling to endeavour to prevent as well as to remove disease, I deem it a question demanding our careful consideration. It is, however, one which nothing short of experimental evidence can decide; consequently, it is our duty cautiously to examine the cases adduced as examples of arsenical poisoning, before receiving them as such; but being satisfied, it is equally our duty to make known our opinions, that the community may benefit by them. I will now, Sir, read my case—

“BELFAST, January 26th, 1859.

“DEAR SIR,—At your request, I have pleasure in stating the particulars of my health, since August, 1856, when

I first occupied my present sitting-room, and for a while experienced no change in my naturally robust health.

“For the first time that I remember, however, I was, the following winter, affected with a sore throat, which I attributed to the dampness of the house, with north-east aspect; but as the warm weather returned, I gradually got better, and was comparatively well in the summer.

“As the winter again approached I was, as before, affected, but to a far greater degree; I had pain in evacuating the bowels, and extreme soreness of the anus; the latter was allayed by your application of nitrate of silver.

“Having at this time occasion to visit the north of England for a few days, I there heard that similar effects were attributed to the poisonous colouring matter in bright green wall-papers, and as my parlour was papered with a rich green flock, immediately, on my return, I removed to the drawing-room, which is covered with a simple gray and gold pattern, and, very strange to say, I was for the rest of the winter perfectly well.

“In the summer of 1858, I was induced, for convenience, to again occupy my parlour, and in a few weeks my throat became sore, and the sides of my tongue most painful from small vertical openings or cracks, as if cut with a knife, which led me to suppose they arose from the teeth, which were accordingly filed, but with little effect; and the tip of the tongue was so sore that to touch my gums was painful. The parts thus affected were treated, as before, with nitrate of silver with little benefit. I removed to my upper room, and in a week or two I was quite well; but wishful to fully satisfy myself, I again returned to the parlour for a few days, but feeling my tongue beginning to be affected as before, I had the green flock paper at once removed, since which I have occupied this sitting-room only, without the slightest return of any one of the previous symptoms; and I now enclose a piece of the green paper, for your analysis, that if found poisonous, others may benefit by my experience.—Dear Sir, very truly yours,

“V. Z.”

“Dr. Wales.”

The first point, Sir, in this case is—Does the paper contain arsenic? I enclosed a portion of it for examination to my coadjutor, Dr. Cuming, and I have examined another portion of it myself, and found it to contain arsenic.

I will now mention other cases in which injurious effects are recorded as resulting from a similar cause.

In the *Medical Times and Gazette*, of May, 1857, Dr. Hinds, of Birmingham, writes, showing the danger to which people are exposed by arsenical paper-hangings. In his case, the symptoms of chronic poisoning

by arsenic were produced, viz., prostration, headache, tightness across forehead, a low febrile state of the system, inflammation of the eyes, and soreness of the mouth and throat. In the same journal, in January, 1858, Dr. Halley writes, saying, "In Autumn, 1856, my study was papered by an emerald-green flock. I worked in it every evening five or six hours, the room being lighted by a single burner. Within a few days I began to suffer from headache, dryness of throat and tongue, and internal irritation. In three weeks I was prostrated, almost losing the use of my left side. Somewhat recovered, I returned to my study, and, after a few days, the symptoms returned and obliged me to desist, until at last I found that whenever I worked for any length of time in this room I invariably suffered from the same sort of symptoms, which did not come on if I remained in other rooms not so papered."

Dr. Halley's attention was directed to the cause of his illness by reading Dr. Hinds' letter, and, on examining the paper, he found *arsenite of copper* in it in the proportion of nearly one drachm to the square foot. He also obtained crystals of arsenious acid on paper saturated in ammonio-nitrate of silver, after exposure in the air of the room for ten hours.

Dr. Alfred Taylor, Mr. Kesteven, and Mr. Gay have detailed similar cases equally convincing, which will also be found in the *Medical Times and Gazette*, but which I need not here enter on, as the history of one is nearly the history of all. Suffice to say, that the fact of such cases occurring in the persons of medical men whose attention has been called to the subject, leads to the inference that many similar cases of disease exist, the result of slow arsenical poisoning, which are ascribed to other causes, and which, were the real cause known, might swell the list of examples of the injurious effects of arsenical green paper to an alarming degree.

So much, Sir, in the affirmative response to the query introducing these remarks. The negative rests chiefly on the testimony of Mr. Fletcher, a paper manufacturer, who says that his workmen enjoy perfect health, though for years they have constantly handled arsenic; and on a Report of the Board of Trade founded on the experiments and observations of their chemist, which sets forth the innocuous characters of bright green flock paper, as regards atmospheric contamination, and which, when published, allayed the apprehension excited by Dr. Hind's letter, and produced the impression that his, Dr. Taylor's, and Dr. Halley's observations might be erroneous. Recently, Dr. Taylor has given reports of cases, and indisputable experimental evidence in support of his former statements and opinions; and I think those who have read what has been written on the subject, will be strongly disposed to answer the query I have put in the affirmative.

Presuming, then, on the injurious influence exercised by wallpapers containing arsenic, it becomes interesting, Sir, to enquire how the poison is conveyed from the walls into the system—in what state, and by what channels.

Dr. Halley says, that at ordinary, or even higher temperature, *with common air*, the amount given off is inappreciably small. That the products of the combustion of gas passed through an aspirator filled with arsenical paper, gave distinct evidence of the imbibition of arsenic in the passage of the air through to the paper—crystals of arsenious acid being obtained from it; and that no arsenic was found in the gas supplied for the experiment. In other words, the *arsenic in the wall-paper is vapourized*, but mere temperature alone is not the chief agent in separating it from the copper with which it exists in combination, but that such vapourization is due to the action of the products of combustion of carburetted hydrogen on the arsenite of copper, by which the former element is separated and vapourized.

Under these circumstances, the pulmonary mucous lining would be the channel by which the poison would be conveyed into the system, and it happens to be a ready and effective one in this very case.

The poison, however, acts on the body, beyond all doubt, in another way—whether only locally, or locally and generally, I cannot say. The dust of the paper (*i.e.*, arsenite of copper with the fabric of the paper), carried from its rough surface by currents of air, or by brushing, will eddy through the room's atmosphere, and will come in contact with, and adhere to the exposed mucous surfaces of the body, and will also be inhaled. May not, therefore, the affections of the eyes, mouth, tongue, throat, &c., be due only to direct irritating contact of the poison, rather than to preceding systemic contamination by it; and may not these differences in the condition of the poison also explain that while in all cases reported we have affections of the mucous surfaces, in some and in the one I have brought forward, we have no constitutional symptoms.

Mr. President, I will conclude these observations by saying, that in this country, where liberty is so extensively enjoyed, that all kinds of poisoning, save malicious, is permitted, the thing being done on a scale of respectable magnitude, diffusion of the knowledge of the danger of papering our rooms with green flock is the mode best calculated to remedy the evil. In Prussia there is a special prohibition to the use of arsenic in the manufacture of papers and paints, arising no doubt from the knowledge of the injury likely to result to the public health therefrom.

Council Ordinary Meeting February 2nd 1859.
Dr. Dill in the chair. Present Drs. Cuming & Wales.

Circular was prepared.

FOURTEENTH MEETING.

5th February, 1859.

The President in the Chair.

{Rough minute book: Dr. Murney, Patterson, Moore, M'Minn, M'Cleery, Dill, Gordon, Halliday, Wales, Ferguson, Pirrie, Reid, Heeney, Ross, Arnold, Johnston, Warwick, Rea, Murney.}

Amputation of Leg.

The PRESIDENT exhibited a leg which he had amputated that morning; it was a case of secondary amputation. The patient I.J., aged 48, came into hospital in September last, suffering from disease of the astragalus of left foot. This disease had existed from the preceding July. On the 25th of October, Mr. Browne removed the foot, commencing the operation as that of "Pirogoff," but finding the os calcis carious, he completed it by "Syme's." On sawing through the end of the tibia, the structure was found to be rather softened. The wound healed rapidly, though extensive suppuration occurred in the sheaths of the extensor tendons, a result, Mr. Browne remarked, which occasionally follows Syme's operation at the ankle-joint.

After the parts had quite healed up and were regaining their natural appearance, the tibia took on disease which necessitated the removal of the limb below the knee. This was done by the double flap, three vessels were ligatured, and the wound was united by metallic sutures. The pathological specimen exhibited a beautiful illustration of the excellent elastic pad which the soft parts of the heel form in cases where Mr. Syme's operation has been adopted; and, as the President remarked, it has yet to be proved that, while Pirogoff's operation gives an additional inch, or a little more, to the length of the limb, it will also afford an equally good point of support, and be as useful as the limb after Syme's operation.

Case of frequent serous discharge from Uterus.

Dr. BRYCE read the following case:—The patient whose case I am to bring before you, is the mother of eight children; the youngest was a year old at the first of September last, and still on the breast. At this period she had a severe attack of hæmorrhage. I may mention that for the previous ten months, she had smart attacks of menorrhagia, occurring at intervals varying from one to three weeks, from the effects of which her health had suffered considerably, and she had become nervous and hysterical. She had a second attack about the middle, and a third about the end, of September.

During the last attack there was discharged a gelatinous-looking mass, very much resembling frog's spawn, but firmer, which was studded with vesicles filled with a light straw-coloured fluid. After the discharge of this mass, there was no return of hæmor-

rhage for four weeks, and the patient was rapidly recovering strength, and I believed that this substance, by distending the uterus, had been the cause of the hæmorrhage. However, it again returned, but now mixed with a serous fluid. After two or three attacks of this kind, the blood disappeared, and there were discharges about once a week, for five or six weeks, of a clear watery fluid, in quantities varying from one to two pints. On one occasion she succeeded in collecting a pint of this fluid. There was sometimes a slight discharge of fluid blood, and at others a clot was expelled before the water. The uterus could not be felt externally, and to the touch internally and when viewed through the speculum, it appeared quite healthy, only there was seen a softish substance plugging up the os, which required to be pushed aside before a sound or other instrument could be introduced.

I at first considered this a case of hydatids, but am now inclined to believe that this fluid was secreted by a false membrane lining the cavity of the uterus, and discharging its contents occasionally. About four weeks ago, I ordered her the carbonate of iron, (by double decomposition); since this period she has greatly improved in health and appearance. There has been no return of the watery discharge for three weeks, but there was, on two occasions, a slight sanguineous discharge which continued for a day. I had tried the injection of the sulphate of alum, but without any apparent good effect.

Scirrhus of the Pylorus.

Professor REID exhibited some morbid parts removed from the body of a patient who died recently in the Union Hospital. The woman, aged 56, was in hospital about three weeks, and gave the following history of her illness:—She stated that, about August last, she began to vomit her food about an hour after taking it, but that the interval gradually became shorter, until now that she rejects it almost immediately. The matters vomited are very sour; she suffers much from thirst; the urine is scanty and the bowels constipated. Her eyes are much sunk, the malar eminences flushed, the skin of the body sallow, and she is greatly emaciated. The abdomen was flat, and a distinct hard tumor was at once detected in the right hypochondrium. Three days after her admission she passed a large quantity of urine, which had been previously scanty. The sp. g. was 1,018, and contained no albumen.

With the presence of such symptoms, there was of course no difficulty in concluding that she was the subject of scirrhus pylorus; but on some subsequent examinations, it was not so easy to confirm this opinion, because the tumor was not to be felt in the right hypochondrium, but had shifted into the locality of the cardiac orifice, and on other occasions was to be

found below the umbilicus. Combining this last locality with where it was first found, I had no doubt of the pyloric orifice being affected; but the vomiting immediately after taking food, and the hardness felt in the region of the cardiac orifice, led me to believe in the possibility of the cardiac end being also involved. The mobility of the tumor, when the pyloric end is involved in cancer, should never be forgotten, as cases have occurred where non-attention to this has led to the disease being undetected. An instance of this fell within my observation about two years ago, in which an eminent physician in another town had for many months been in attendance on a lady suffering under the usual symptoms of scirrhus pylorus, but had failed to detect the disease in consequence of not searching for the tumor sufficiently low down, where there was no difficulty in detecting it below, and to the right of the umbilicus. Some days she would reject everything; again she would take and retain large quantities for a period of 48 hours; and again the quantity rejected appeared far in excess of what she had taken into the stomach. Latterly the matters vomited had all the characteristics of what has been described as “coffee grounds.” In this, as in several previous cases, I found a combination of sweetmilk, whiskey, and lime water, to be retained when taken in small quantities at stated intervals, when all other kinds of nutriment had been rejected. There was present in this woman what I had observed in a few other similar cases, viz., that when commencing to examine the abdomen, its parietes would be found flat and retracted to the spine, but soon after the withdrawal of the hand, the stomach would be observed to swell up, raise the parietes, and contract like a worm from end to end. She required aperient medicine and enemata till the 26th ult., when diarrhoea set in, and continued till death, on 3rd instant, the evacuations resembling coffee grounds, and being very foetid. On *post-mortem* examination, it was found that the stomach had contracted no adhesions to any neighbouring organ, and, as is generally the case when the pyloric orifice alone is diseased and greatly contracted, the cavity of the viscus was greatly enlarged, capable of containing several quarts, which at once explained how the tumor was to be felt in different localities. The pylorus was surrounded by a hard ring of scirrhus, and so contracted that it only allowed a No. 10 catheter to pass into the duodenum. There was no scirrhus deposit in the liver or mesentery. The small intestine was natural to within about one foot of the cæcum, when it was found invaginated; the upper portion being inverted into the lower. The uterus was found very small, it and the rectum healthy. The spleen unusually small, and free from any morbid deposit. The kidneys large and healthy in structure. The supra renal capsule enlarged considerably; there was, however, no discoloration of the skin

during life, as has been observed by Dr. Addison in connection with disease of these organs.

Case of Chlorosis—Anæmic Murmur at Apex of Heart.

Professor REID then stated that a chlorotic girl was, three weeks ago, admitted into the Union Hospital, in whose case there were some points of interest, and who gave the following account of her health:—About two years ago, the catamenia had been too profuse, which medical treatment, however, soon restrained, without her strength or usual ruddy complexion being at all diminished. About twelve months since she complained of pain in the epigastrium, suffered from vomiting, and found her strength, appetite, colour, and catamenia gradually diminishing, the latter still appearing at the regular periods. About eight months ago, she began to suffer from palpitation and breathlessness on going up stairs, or on making any exertion, with throbbing in the back of the head, noise in the ears, and often pain in the right side of the head. She was certain that, from the attack of menorrhagia two years previously, there had been no debilitating discharge of any kind; neither epistaxis, hæmorrhoids, hæmatemesis, nor leucorrhœa.

She sought hospital treatment on account of palpitation and debility. On admission, her eyes, naturally large, were very bright; the conjunctiva, the lips, the gums, and tongue bloodless. The skin of the face and body was pale yellow, and free from œdema about the ankles, although the stethoscope leaves a slight depression on the chest. There was no evidence of organic disease of either the lungs, the liver, or spleen, and she had never had intermittent fever; and as she had always been well fed, and clothed, and kindly treated in a gentleman's family, I had no difficulty in making my diagnosis that she suffered under chlorosis, fairly attributable to the affection of the digestive organs, which appeared one year previously. When the hand was laid over the heart, its action was found irritable; percussion did not detect any enlargement. The stethoscope revealed the existence of a distinct systolic murmur in the second left intercostal space, and extending towards the left shoulder, in the locality of the pulmonary artery. A murmur very much fainter was heard over the sternum, rather lower down, or in the position of the aorta. The second sound of the heart was quite distinct. Over the body of the ventricle, no murmur was heard, but finding the apex of the heart, and placing the stethoscope over it, a distinct murmur was also heard at the period of the heart's systole. There was also heard a continuous murmur in the jugular veins, most distinct in the right; but I could detect none over the site of the longitudinal sinus or the torcular herophili, where in similar cases a murmur has been heard. This girl was positive that she had never suffered from rheumatism in any form, nor had any symptom that would

indicate the presence of a previously inflammatory state of the heart; and as she is remarkably intelligent, and gave a most connected account of her illness, I have every confidence in her statement. My reason for bringing this case before the Society, is the presence of murmur at the apex of the heart, in a chlorotic female; and I have been compelled to go more fully than I wished into the history of her health, and the symptoms present on her admission, because the existence of such a murmur, independent of organic disease, is still a disputed point, and the bare possibility of its occurrence has been only recently, and indeed but very partially admitted—as may be learned from the following extracts on the literature of the question:—Dr. Hope “considers that an inorganic murmur is confined to the aortic orifice.” Dr. Latham appears to hold the same opinion. Dr. Davis states, “that functional murmur is exclusively situated at the base of the heart.” Dr. Bellingham writes, “that the systolic bellows murmur in organic affections of the heart, has its seat at the aortic orifice, and is not audible at the apex of the organ.” Dr. Hughes states a similar opinion. Dr. Markham “believes that mitral systolic murmurs invariably indicate a defective condition of the mitral valves and are never inorganic—he is not prepared to admit or deny, that spasmodic contractions of the papillary muscles, the tendons of which are inserted into the mitral valves, may occur, and so prevent the closure of the mitral valves for a certain period.” Dr. Walshe states “that hæmic murmurs are invariably basic in seat, systolic in time, only in exceptional cases audible below nipple, and never perceptible as far as left apex.” He admits “that a dynamic murmur,” that is, a murmur dependent on some “abnormal state of the heart’s action, as in chorea, and probably in other nervous disorders, is heard at left apex, owing to a disordered action of the muscular apparatus of the valve.” He has “never seen a murmur at left apex of purely blood origin, and has never heard, in a purely chlorotic woman, a murmur having all the characters of a mitral regurgitant one.” Dr. Stokes advises us “to be cautious in rejecting the opinion,” that inorganic murmurs may not be seated in the mitral orifice, “as he believes that he observed cases of inorganic murmurs, which, so far as physical signs went, were closely similar to those of ordinary regurgitant disease.” Dr. Stokes has recorded two most instructive cases, in which organic disease of the mitral orifice was associated with chlorosis. In one there was marked lividity of the lips, until the chlorosis was cured, the systolic murmur at apex remaining, the lady dying suddenly some years afterwards. The other had previously suffered from an attack of pericarditis, and *post-mortem* examination proved the existence of organic disease of the mitral orifice. Dr. Barclay “is quite certain that an anæmic murmur is occasionally heard of greater intensity

towards the left apex.” It would thus appear that Drs. Stokes and Barclay are the only authors who admit that a blood murmur may exist at the apex of the heart, independent of organic disease. It is strange that, notwithstanding many sudden deaths in chlorosis, we have no record of any *post-mortem* examination in a case in which a murmur at the apex had been heard in chlorosis, except where there existed during life evidence of organic disease.

Dr. REID remarked, that as there was neither cough, nor hæmoptysis, nor lividity of the lips, nor any symptom that would indicate regurgitation through the mitral orifice, he was disposed to believe that the murmur at the apex was caused by the friction of the spanæmic blood against the *columnæ carneæ* of the ventricle, the sound being conveyed to the surface by the apex of the heart when in contact with the side; and that from this case we should draw the practical lesson, that we are not hastily to decide, that when a murmur is heard at the apex, therefore organic disease of the mitral orifice must be present, always bearing in remembrance that Dr. Stokes has proved that such disorganization may co-exist with well-marked chlorosis, and remain and cause death after the chlorotic murmurs had been removed. This patient derived marked benefit from the administration of iron, the colour of the lips and tongue improving greatly; the murmur much less distinct at the second intercostal space, and not constantly heard at the apex.

Council Ordinary Meeting February 9 1859.

The President in the chair. Present Drs. Dill, Murney, Cuming, & Wales.

The circular was prepared.

FIFTEENTH MEETING.

12th February, 1859.

The President in the Chair.

Porriigo existing only on the Chest.

Mr. H. M. JOHNSTON having, at the last meeting of the society, introduced a child, aged 2 years and 4 months, on whose chest a solitary spot of disease existed of six weeks’ standing, which he believed to be porriigo; and some diversity of opinion having arisen as to its nature, in consequence of no trace of eruption having appeared on the scalp, it was ordered that the crust should be examined microscopically. Accordingly,

Dr. CUMING stated, that, having examined the crust, he had been able to identify the parasite, so that the disease was undoubtedly porriigo.¹

¹ On the inaccuracy of this test, see paper by Jabez Hogg, Esq., read before the Medical Society of London, page 110.—ED. D.H.G.

Dr. WALES exhibited the *achorion schænleinii*, the vegetable parasite of the crust in question, under the microscope.

Case of Placenta Prævia.

Dr. HEENEY read the following case:—On the 8th of November last, I was hastily summoned by a junior member of the profession to render assistance in a case of excessive hæmorrhage from the womb, occurring in a parturient woman in the ninth month of her pregnancy. On arriving at the bed-side, I found the patient in a state of extreme debility, and it was with great difficulty that any pulsation at the wrist could be found; her extremities were cold, and her face quite pallid, although her head was placed low. The patient was too weak to give me any information at the time, but I was informed that she had previously several attacks of flooding.

I afterwards learned from the patient herself, the following details: She is about 35 years of age; the mother of six children; and there was nothing unusual in the present pregnancy beyond a constant pain in the back, which, however, disappeared on the occasion of the first hæmorrhagic discharge, which took place on Monday, exactly sixteen days before her delivery. She found occasion to empty the bladder, and, whilst doing so, she remarked upon the unusual quantity of fluid which was passing from her, and was surprised and horrified to find that the chamber utensil was literally overflowing with blood. She lay down, and the hæmorrhage ceased till the second day afterwards, when it again returned without pain or warning of any sort, and there issued, according to her own estimation, about three or four pints. She now felt very weak and alarmed, and sent for an accoucheur, who, upon visiting, found the hæmorrhage had ceased, and ordered the continuous use of a mixture, with a view to bring on labour pains. He then left her and did not return. She drank the entire of the mixture, but without the desired effect.

On the Sunday following she had another attack, then on Tuesday, and finally, on Wednesday, two other attacks—the first at two o'clock, p.m. This left her in a very alarming state, when another accoucheur was summoned. He found it necessary to administer stimulants, and some local applications to the genital organs, and, I believe, not suspecting unavoidable hæmorrhage, resolved on waiting the efforts of nature for the expulsion of the fœtus. He left the patient to repose, as the hæmorrhage had ceased, but was summoned in two hours afterwards, as it had returned with force, and he was so alarmed at the quantity lost, and the great prostration, and almost moribund condition of the patient, that he demanded assistance, when I was sent for. Before I arrived the hæmorrhage had ceased. I then proceeded to a careful examination. I found the os uteri pretty high up,

but dilated to nearly the extent of half-a-crown, and somewhat dilatable; the anterior half of the circular opening of the womb was covered with a fleshy or fibrous substance, which I readily concluded to be the margin of the placenta, and whose presence in this situation was the cause of the previous hæmorrhage. I then endeavoured to find out the part of the child presenting, but was unable to do so, as I could touch nothing within but the membranes filled with the waters. The hand, however, I afterwards discovered to be the presenting part, but the water behind, and the placenta attached principally to the cervix anteriorly, prevented me from then ascertaining that point.

I found myself now in a critical position. To wait for the efforts of the womb, and another attack of bleeding, would be to consign the woman to certain death, and to turn, in her present depressed and anæmic condition, would be attended with considerable risk, and, if unsuccessful, with perhaps no small amount of obloquy. However, a sense of duty compelled me to adopt the latter alternative, which was readily agreed to by my colleague; but, as I have said before, that he was a young practitioner, I thought it prudent to seek the opinion and consent of an experienced accoucheur. As the bleeding had again ceased, there was time to send for one, and I thought it right, in the meantime, to give as much stimulus as she could take, which was little, owing to the difficulty of swallowing.

Dr. Wales was the gentleman sent for, who, after hearing the case as far as I could explain, and after due examination and deliberation, concurred with me that immediate delivery was the most proper course. On introducing my hand within the os, and behind the margin of the placenta, I experienced no resisting *contractile* efforts, but it was with some difficulty that I got the hand introduced. I then ruptured the membranes, and sought the foot of the child. I could not conveniently grasp more than one, and brought it down, and there was no difficulty till the breech came low enough to pass the os, the passage of which occupied a considerable time, as there was a steady *passive*, though not *active* resistance. However, by steady perseverance and repeated tractile, though not violent, efforts, the delivery was accomplished. The placenta immediately followed, and I never saw a delivery where there was less loss after the expulsion of the fœtus, which was stillborn. She had no labour pains from first to last, but I thought I perceived some slight bearing efforts on her part during the latter part of the delivery. The woman is now perfectly well, but it was several weeks before she could leave her bed from debility alone. She had no subsequent inflammatory symptoms, but the pulse ranged high for a considerable time after delivery; it however gradually improved under the use of hæmatics and nutritious diet.

I am happy to think, that cases of placenta prævia do not often occur, as, although I have practised pretty extensively for many years, I never met one before. I adduce this instance to illustrate the danger of leaving cases to nature where the loss and weakness have been so alarming—a course advised by some authors, and as confirmatory of the views of those who deprecate delays. Such cases are extremely perplexing even to the experienced practitioner. My opinion, however, corresponds with the teachings of those who recommend delivery as soon as the *dilatable* state of the os uteri will permit, and not to be deterred from interfering even where the loss and debility have proceeded to an extreme degree, (whether from neglect or ignorance of the consequences, as in the present instance,) as immediate delivery affords the best, if not the only, chance of rescuing the unhappy patient from the jaws of death.

Bigg's Orthoæpede.

Dr. WALES next exhibited an instrument, invented by Mr. Bigg, for use in equino-varus. He said he had been using it for some time, and with modifications had found it to answer the purpose for which it was intended. The mechanical merit of the instrument consisted in the simplicity and ingenuity of the arrangement by which three distinct movements of the foot-piece could be produced by acting on one centre; these movements were eversion, rotation, and elevation of the anterior portion of the foot, and consequent depression of the heel, such motions as were requisite for the restoration of the foot affected with equino-varus to the normal position. In slight cases, the use of this instrument would suffice for a cure, without surgical interference; but when the latter was necessary, it became still more useful. The instrument being adjusted to the deformed position of the limb, and section of the tendons being performed, it maintains the foot immovable, until the new bond of union safely admits of elongation, which can be so gradually and steadily accomplished that all risk of loss of power from imperfect or weak union is avoided.

To keep the stem of the instrument, however, firmly in the middle of the lateral aspect of the leg required extension of the short thigh stem to the hip joint, and its pivot attachment there to a pelvic band. This addition renders the instrument very effective. He further said, that though the instrument answered exceedingly well for very young children, he preferred, where a child is *about walking*, dispensing with it altogether, and operating at two distinct periods. His plan was to convert *equino-varus* into *equinus*, by section of resisting structures and *immediate* extension on a common straight splint. Eversion being complete, he next divided the tendo-achillis, and by simple mechanical means, brought up the foot *gradu-*

ally to a right angle with the leg, which position, with proper and common appliances to the foot, will be maintained by the weight of the child's body in its attempts to walk or support itself.

Fractures of the Acromial End of the Clavicle.

Professor GORDON read the following case:—As the following case and specimens of fracture of the clavicle, near the acromial end, have an important bearing on the present knowledge of such accidents, I have, therefore, been induced to bring this matter before the Society, more especially as the conclusions at which I have arrived are different from those of Dr. R. W. Smith, whose work on fractures and dislocations embraces, with some trifling exceptions, almost all that is known on the subject.

A carpenter, aged 30, whilst assisting in carrying a heavy piece of timber, on the 19th January, 1859, fell at least from a height of 20 feet, in his descent striking the side of the wall, and alighting on the posterior and outer part of right shoulder and axilla. About an hour after the accident I saw him. He was in a shed adjoining the place where he had fallen; he was sitting on a form, leaning slightly forwards and to the right side. His sole complaint was of severe pain in the right hypochondrium and upper and back part of axilla. On passing my hand beneath his clothes, and desiring him to take a deep inspiration, I was unable to make out any fracture of the ribs; but as the attitude in which he sat and the way in which he had fallen, led me to suspect fracture of the clavicle, I next proceeded to examine that bone. On carrying my finger along its upper surface, when I arrived within $\frac{3}{4}$ of an inch of its acromial end, the continuity seemed to be lost, and pressure here caused him to wince; but the pain was very trifling indeed when compared with that experienced when the trapezius was pressed forwards against the seat of fracture. He was directed to be taken home and to go to bed for a further examination.

On visiting him shortly afterwards, I found him sitting up, being unable to lie down from the severe pain in the right hypochondrium and back part of axilla; but as the most careful examination of these regions did not reveal either crepitus or inequality of the external surface of the ribs at the seat of pain, I regarded it as proceeding from muscular contusion. I now requested him to raise the arm, which he did slightly, at the same time flexing and extending the fore-arm upon the arm with tolerable freedom, and without complaint of pain. On exposing the shoulder, it was found to be more depressed, and the spinal border of the scapula more prominent than that of the opposite side. When measured from the acromion to the sternal end of the clavicle, there was shortening to the extent of half-an-inch. On carrying my finger along the anterior border of the clavicles, on

arriving near the acromion, the anterior concavity was much deepened; the outer, or acromial fragment formed almost a right angle with the sternal portion, which seemed to be displaced backwards. On the upper surface both fragments were on the same level. Pressing the trapezius forwards opposite the fracture caused very acute jaggings pain. No crepitus was detected by slightly raising or depressing the shoulder. However, as he suffered very acute pain in the right hypochondriac and axillary region on the slightest motion of his body, and as the signs of fracture of the clavicle were quite conclusive, no further attempts were made to elicit crepitus. A large pad was placed in the axilla, and a figure of 8 bandage applied, which removed almost completely the inclination forwards of the acromial fragment of the clavicle.

Dr. Smith, to whom we are indebted for pointing out this displacement forwards of the outer fragment, says—"From an examination of these preparations, we learn that the outer end of the clavicle may be broken either between the coraco-clavicular ligaments, or between the trapezoid ligaments and the acromion; and that fracture in the former situation is of comparatively rare occurrence, and attended with scarcely any displacement of either fragment of the bone; but that in the latter, contrary to what is usually stated, there is generally a considerable amount of displacement. The specimen of fractured clavicle which I now exhibit, and which I shall call No. 1, resembles so accurately that of No. 3, page 22 of Dr. Smith's work, that if we had a like horizontal section in it, it might almost be said that the drawing was a faithful representation of it.

But was this a fracture external to the trapezoid ligament? Unquestionably not. The trapezoid ligament was attached, in any dissection made by me nearer to the acromial end than $\frac{3}{4}$ of an inch. From half-a-dozen of examinations recently made, half-an-inch would represent the average distance between the trapezoid ligament and the acromio-clavicular articulation. In this specimen the fracture is a little more than one inch from the acromial end, and yet the acromial fragment forms almost a right angle with the sternal. This specimen, which I shall call No. 2, I dissected to-day (Feb. 12th, 1859). The acromial, or outer fragment, is on a plane, about a line above the sternal portion; it is so much displaced forwards as to form an angle of about 43° with it. The fracture is oblique from before backwards, and from above downwards and outwards; it commences four lines internal to the acromio-clavicular articulation, and running obliquely backwards and inwards, terminates opposite the posterior and outer border of the root of the coracoid process; and yet the most careful examination shows that, although from its obliquity the line of fracture is nearer to the acromio-clavicular articulation on its under surface than above, there is

none of it external to or between the trapezoid ligament and the acromio-clavicular articulation. The conclusions to be drawn from the case related, and from the two specimens exhibited, are—That in many instances of fracture between the coraco-clavicular ligaments, the outer or acromial fragment is so displaced as to form a right angle with the inner or sternal portion, the upper surfaces at the same time maintaining the same horizontal level, or, as in No. 2 specimen, with the acromial fragment, on a plane somewhat above the sternal fragment. When the clavicle is broken between the attachments of the coraco-clavicular ligaments, the scapula rotating on an axis nearly corresponding to its anterior border, falls forwards and inwards. The acromial fragment is thus brought into relation with the anterior border of the sternal portion, and, if the accident has been overlooked, unites at right angles with it. That the attachments of coraco-clavicular ligaments do not oppose any obstacle to the outer fragment being applied to the anterior surface of the inner, and, when we have fracture between these ligaments without displacement, it must be referred to some other cause rather than to the resistance offered by these ligaments.

That the chief agents in causing displacement are the same as those in the ordinary fracture in the middle third of the clavicle, excepting the subclavius muscle. That the outer end of the inner or sternal fragment seems to be displaced backwards, but this is more apparent than real from the shoulder falling forwards and inwards. From the inclination forwards and inwards of the shoulder, the outer end of the sternal fragment comes into more close proximity to the trapezius. Hence, when we press on that muscle opposite the fracture, it becomes applied against the broken end of the sternal fragment, causing a jaggings pain, much more acute than when pressure is made over any other part of the fracture. That, from the shape of the clavicle, fracture is most likely to occur at the centre of, or a little external to, the centre of the posterior concavity, than between the trapezoid ligament and acromio-clavicular articulation. That, from the attachments of the coraco-clavicular ligaments and the two specimens exhibited, I am of opinion that many of the cases of fracture of the clavicle described by Dr. R. W. Smith as external to the coraco-clavicular ligaments, are really between them, and that his observations apply more correctly to the fractures between, than to those external to, the coraco-clavicular ligaments.

Council Ordinary Meeting February 16 1859.

The President in the chair. Present Dr. Dill, Dr. Murney, Dr. Heeney, & Dr. Wales.

The circular was prepared.

SIXTEENTH MEETING.

19th February, 1859.

{Rough minute book: President, Dr. Ferguson, Patterson, Wales, Heeney, Moore, Harkin, Mulholland, Reid, Rea, Warwick, Murney, Bryce, Murray, Patrick (Carrickfergus), M'Minn, Dill, M. M'Gee, Johnston, Dunlop.}

Fatty Tumour of Back of Neck.

Dr. MOORE exhibited a cast of a fatty tumour of the back of the neck, extending from the occipital protuberance to the first dorsal vertebra, and measuring in its transverse diameter about 6 inches.

About twelve years ago Dr. Moore had been consulted by the gentleman who was the subject of this growth, who was then in his 72nd year, with regard to its removal. Dr. Moore at that time advised, considering his age, non-interference, remarking that it would be a tumour to him all his life. His death was caused by a railway accident, necessitating the removal of both legs below the knee four days after the receipt of the injury. Dr. Moore believed that he would have recovered from the effects of the amputation but for an injury of the spine, which he received at the same time, causing paraplegia.

Chopart's Operation.

The PRESIDENT exhibited a foot, which he had amputated that morning, by Chopart's operation, for disease of the internal cuneiform and cuboid bones. The only remarkable feature in the case was the small evidence there was, at first, of such extensive disease as was exhibited by the tarsal bones, and the rapidity with which they had become disorganised; the internal cuneiform especially was almost completely transformed into tubercular softening. The soft parts in the dorsum of foot had also taken pulpy degeneration. Three vessels had been ligatured, and the edges of the flaps had been brought together by metallic sutures. The patient was a young countryman, aged 24 years.

Uterine Tumour.

Dr. MURNEY placed before the Society a specimen of a uterus, which he considered was an example of the fibrous tumour of that organ; it was taken from a subject in the anatomical rooms of Queen's College. He said—Unfortunately, I am not able to give any history of this case. On inquiry, I have been able to learn only the two facts, that the woman was 40 years of age, and has been an inmate of the idiotic ward in the Union Workhouse for some time past. She was very much emaciated. There was complete absence of mammary development; no fatty deposit at the region of the mons veneris, and there were extremely few hairs about the pubis; altogether, a superficial exam-

ination would have led to the inference it was the body of a girl about 18 years of age, who had never menstruated.

The brain was normal in every respect; the viscera of the abdomen were also healthy, with the exception of the uterus, which was somewhat spherical in shape, nodulated, about the size of a cricket ball and half. The tissue of the organ was not of uniform density; some portions of it were of a natural firmness, others much harder. The "os" was transverse and the margins cicatrized, having evidently been ulcerated at some period. In two instances the nodosities were connected to the tumour by very narrow peduncles. The whole weight of it was 8 oz. 6 drachms, the average weight of healthy specimens being, for the virgin 6 to 10 drachms, and from 1½ to 3 ounces in females who have borne children.

Having cut into the specimen in the presence of the Society, Dr. Murney called attention to the fibrous deposit which had taken place in the two customary situations—viz., on the surface of the uterus, beneath the peritonæum, and in the interior, close to the lining mucous membrane. From the appearance of parts of the section, and the manner the knife cut through it, he was inclined to think portions of the new deposit were undergoing malignant change. Parts of the suspected structure were taken for microscopic examination by some of the members.

Fracture of Neck of Femur.

Dr. MURNEY then showed an example of intra-capsular fracture of the neck of the femur, also met in the anatomical rooms of Queen's College during the past week. The specimen consisted of the articulating part of the bone, connected by a quantity of fibrous structure to the upper end of the shaft between the trochanters. Every portion of the neck had been removed by absorption. The capsular ligament was very greatly thickened, and the muscles around the joint, particularly the glutæi medius and minimus, had undergone fatty degeneration from non-use. The presence of intra-capsular fracture had been recognised when the body, that of a female, was received for dissection, as there was eversion of the foot, shortening of the limb to the extent of one half inch, and upon rotation the trochanter rolled upon its own axis.

Dr. MURNEY remarked—On looking at this specimen, I find the portion of the head which remains exactly corresponds to the superior epiphysis of the thigh. It may be recollected that in the case in which the President performed amputation at the hip joint, and about which case some difference of opinion existed as to the pathological changes, one portion exhibited was precisely similar to this one; also, in a case forwarded to the Society by Dr. Babington, of Londonderry, the same extent of bone occupied the

acetabulum. These instances, and others I have seen, lead me to conclude that at all periods of life the epiphysary, and perhaps the apophysary parts of long bones, receive their nutrition independent of the supply given to the shafts. We know, of course, that, during the development of the bones, the progress of each centre is in a great measure independent of those parts to which it is as yet imperfectly connected, but about the age of 25 years, ossification is completed. This person, a woman, was 65 or 70; Dr. Babington's patient was, I think, 40 or 50; and Mr. Browne's case was 26 or 27 years of age. In two at least of these we might have expected the circumstances which caused removal of the neck of the thigh would also have carried off the head, had both those parts been nourished from the same source; but as I believe they derive their supply of blood from different vessels, we can readily explain why certain parts are so frequently to be found cut off from the remainder of the bone at precisely the same situation.

Dr. Dill introduced the discussion of the Placenta Prævia by asking for adjournment and recommending that it should *take precedence* of all others.

Council Ordinary Meeting February 23rd 1859.

Present, the Secretary.

The circular prepared.

SEVENTEENTH MEETING.

26th February, 1859.

Deformity of Hand, with Operation.

Dr. GORDON presented a boy, 8 years of age, on whom he had operated eight months ago, for a deformity of the hand from a burn. The boy was two years of age when the accident occurred, and being weak and delicate, his mother said, "I did not pay sufficient attention to him, thinking he would not live long." Shortly after the commencement of last session, Dr. Halliday brought him before the Society.

After that this cast was taken, on his admission into hospital. The hand is flexed at an acute angle with the forearm, and the proximal, or upper end of the carpus, and its dorsal surface, projects downwards, so that when he falls forwards the upper and back part of the carpus comes in contact with the ground. The palmar aspects of the ulnar site of the hand, and a considerable portion of the little finger, are united to the anterior surface of the lower fourth of the forearm. On the radial side, the ball of the thumb is approximated to the forearm, but the cicatrix does not extend so high by an inch as on the ulnar side. The hand is thus not only greatly flexed, but also very much adducted and slightly rotated, the

palm looking upwards and towards the radial border. The thumb is so much bent backwards that its phalanges form an acute with its metacarpal bone, the dorsal surfaces looking towards each other. The band of skin which has thus bent the thumb backwards proceeds from the root of the nail, burying, as it were, the whole thumb except its apex. The fore and middle fingers are free, but the ring finger is held very much flexed, whilst the little finger is greatly adducted, and held against the ulnar surface of the forearm.

The boy was put under the influence of chloroform, and a V incision, its apex upwards, was made through the band uniting the ulnar side of the hand to the forearm. The angular flap was next dissected downwards, until the hand formed an obtuse angle with the forearm. A similar V incision was made on the radial side. After that the two sides of each of the V incisions were approximated transversely by sutures, the water dressing applied, and extension maintained by a splint passing along and beyond the back of the forearm and hand. When these incisions had cicatrized, and when the hand had been brought on a line with the forearm, a V incision was also made in the cicatrix, which held back the thumb. The state of the parts at present are—The hand is on the same line as the forearm, with the exception of a very slight inclination towards flexion. The thumb is inclined backwards, but not to the same degree as before operation, its extremity, as high as the second joint, being free. The ring finger is considerably flexed by a contracted band. The little finger is so flexed, deformed, and incapable of motion, that it would not be possible to make it of any use to him.

{Rough minute book: Professor Gordon also exhibited a specimen of extra-capsular fracture of femur.¹

Professor Gordon exhibited an amputated limb from scrofulous disease of knee joint.}

Cases of Placenta Prævia, by Dr. DILL.

It will be admitted by all who practise obstetric medicine and surgery, that there is no one complication in midwifery attended with more danger to the patient, and difficulty to the practitioner, than those cases wherein the placenta presents, and unavoidable hæmorrhage occurs. Under circumstances of such extreme peril to the patient, the accoucheur may be said, indeed, to be actually combating death. With such facts before us, and acknowledging the serious responsibility that presses upon us, we are imperatively required to be not only intimately acquainted with the symptoms, but to analyse thoroughly and impartially, and examine carefully, the different methods of treatment which have been from time to time recommended by the various authorities, so as

¹ [See page 780 for details of case.]

to come to a safe and satisfactory finding regarding the management of placenta prævia. It is not necessary for us here to pause and inquire how it comes to pass that the placenta is occasionally to be found planted over the os uteri, and at times in its immediate vicinity. It is only required of us, at the present time, practically to know that such cases do exist, and that we may be suddenly and unexpectedly called upon to deal with placental and partial placental presentations. Placental presentations are to be diagnosed, first, by the sudden attacks of discharge of blood from the uterus, usually commencing with the sixth month of pregnancy, and recurring occasionally until the full period of gestation arrives, or until the approach of labour. Second, by a vaginal examination, when a firm, fibrous, and fleshy sensation is communicated to the finger by the part presenting. Third, by the body conveying such a sensation being attached to the inner side of the os uteri; and fourth, by a loose membranous-like substance hanging down through the os, when the placental presentation is partial. The different modes of managing cases of placenta prævia, may be briefly stated in the following order:

The first plan proposed may be said to be the use of the “tampon,” or the plug. This practice is only indicated when the os is not dilated sufficiently, or dilatable. Under these circumstances, I have used the “tampon” with advantage. The only objection to it is, that hæmorrhage may go on inwardly.

The second is the puncturing of the membranes, which has been practised from a very early period, and I would merely allude to one very formidable objection, viz., that should turning be the practice required at any future period, it is found to be much more difficult, if not dangerous, in consequence of the evacuation of the waters, and the contraction of the uterus.

The third is the partial separation of the placenta. With this proposal, which originated with Dr. Robert Barnes, I shall not occupy your time, as it does not recommend itself to my mind in any case; I shall only say, that in most cases of partial presentation, we have at a certain stage a partial separation of the placenta without any good results following.

The fourth is the complete separation and extraction of the placenta before the child; and the fifth is what I would consider the grand and the chief operation in placenta prævia—viz., the turning of the child.

The fourth and fifth plans of treatment appear to me to be the modes of managing cases of placenta prævia, with which we have principally to do, and which have occupied the minds of the profession as rival or antagonistic operations since 1844, when Dr. Simpson revived the plan as proposed by Mr. Wood and Dr. Radford, viz.:—the separation and extraction of the placenta before the child. We have now to take up and carefully inquire into the merits and demerits

of that proposal which has been made, of artificially separating and bringing away the placenta before the child. And this practice having had the advocacy of Wood, Radford, and latterly of Simpson—men of such high standing—we are bound, before condemning it, to give it our best attention. Dr. S. appears to think that this operation should supersede the operation of turning; but the theory and arguments which have been advanced in its favour, and which he makes the basis of his practice, are not (as I shall show) to be relied upon. The recommendation is founded upon the hypothesis, that the flooding comes from the cells in the placenta—not from the uterine vessels—and if this can be sustained by facts and arguments, then, indeed, should the placenta, the source of the discharge or hæmorrhage, be the body first removed. No satisfactory proof can, however, to my mind be given, that the great quantity of blood which flows in these cases, proceeds altogether from the placenta. Is it at all likely that this large quantity of blood should come from such a small portion of detached placenta as is usually at first separated? Besides, if the extremities of the blood-vessels on the surface of the placenta be open at all, they must of necessity be very minute. Some anatomists and physiologists assert that they have not open mouths, and Dr. H. Madge, who instituted a series of experiments, established the fact that the vessels on the surface of the placenta are shut sacs. The experiment was this: he injected the umbilical vein with a quantity of coloured fluid, and in place of escaping at the surface of the placenta, the fluid returned by the arteries. On the other hand there are strong and valid reasons for believing that the mouths of the vessels on the inner and stripped surface of the uterus, are the principal sources of hæmorrhage in placenta prævia. The size of these vessels in the mouths of the sinuses which will expand at the mouth and neck of the uterus with each pain, at which time an increased quantity of blood is discharged, furnish satisfactory arguments in favour of the opinion that the flooding comes directly from the uterus. Moreover, Dr. Simpson himself states, that there is a greater development of the uterine blood-vessels in the neighbourhood of the placental attachments, and also a larger determination of vital fluid to this quarter. And hence, we must most naturally infer, that when the placenta is separated, the flow of blood from this part of the uterus becomes excessive.

As often as I have examined the portion of separated placenta, so often have I observed that the surface and cells were coated and filled with coagulated blood. The fact is also on record, that although the placenta has been separated and expelled, the flooding has continued. We may also adduce post-partum hæmorrhage, as a very strong argument in favour of the opinion that it is from the uterine vessels the discharge comes. No doubt hæmorrhage has occa-

sionally ceased by extracting the placenta before the child; but this is to be ascribed to, and accounted for, by the fact that the head of the child is pressed down, and shuts up the mouths of the uterine vessels. But admitting that this may occur, and although the placenta may become spontaneously detached and lodged in the vagina, from which of necessity it must first be removed, yet this does not satisfactorily prove the propriety of artificially separating and extracting the placenta in all cases before the child is delivered. Nay, more, I believe I have advanced arguments strong and sufficiently numerous to deter the practitioner from such a mode of procedure. We now have arrived at that point at which we shall consider the most important operation in placenta prævia, viz., turning, which operation, if performed judiciously, and at the proper time, gives us the best chance for preserving the lives of both mother and child, as I shall endeavour to show, in the favourable results which flow from this practice, in the relation of a few cases which lately came under my own observation:—

Case 1.—Mrs. C., aged 30, April 21st, 1858, Keegan-street.—Mr. J. called me to see this patient, who was far advanced in pregnancy, and had been attacked with profuse uterine hæmorrhage once or twice during the eighth month, and now again towards the close of the ninth. The placenta was felt adhering at the neck of the uterus; the os was about the size of a crown piece, and dilatable. The woman was weak, but there were symptoms of a living child. She was put under the influence of chloroform. I introduced the left hand, the os easily yielded, passed onward, punctured the membrane, got a hold of one foot, turned, and delivered her, in the usual way, of a living child. The placenta very soon followed; the hæmorrhage ceased; the woman did well; the child died within a week.

Case 2.—In June, 1858, I was called, by Drs. S. and J., to a woman residing in Fourth-street, who had been attacked with profuse hæmorrhage at the close of the ninth month of pregnancy. She had been ill for nearly two days when I saw her. The edge of the placenta was protruding through the mouth of the womb. The waters had been discharged some hours. The woman was weak, and life in the fœtus could not be detected. It was agreed that turning was the proper course. Dr. J. introduced his hand, got hold of a foot, turned, after some difficulty, and brought away a dead child. Marshall Hall's plan of treatment was vigorously instituted, but without effect. The mother did well till the tenth day, when she died, but as I did not see her after being delivered, I cannot state the particulars.

Case 3.—Mrs. M. was brought into the Lying-in-Hospital in a very weak and exhausted state from hæmorrhage, about the full period of gestation. The placenta presented. Dr. Pirrie, whose patient she was,

finding the os but slightly dilated and rigid, thought it better to introduce the “tampon.” It remained in for four hours, during which time the pains had increased. The “tampon” was removed. The os was found to be farther dilated. She was placed under chloroform. Dr. Pirrie introduced the hand, turned, and delivered; the child was dead; the woman made a good recovery.

Case 4.—On the 10th of September, 1858, Mrs. F., aged 33, took ill of flooding at 5 o'clock, a.m. I was with her at 6 o'clock. She had completed the sixth month of pregnancy. She had lost a good deal of blood, and the discharge was continuing. The placenta presented; os, size of half-a-crown and rigid. I introduced the “tampon,” applied cold, and admitted cool fresh air into the room. Mrs. F. was a delicate woman, and she had become rather weak. I was soon afforded the assistance of Dr. P., when we agreed to administer chloroform, and deliver. I introduced the right hand into the vagina; found the os more yielding, so much so as to enable me to introduce two fingers; found it to be a cross birth; hooked one of my fingers into the groin of the fœtus, and soon brought it away; being premature, the fœtus was of course dead, but the mother made an excellent recovery.

Case 5.—On the 12th of July, 1858, at two o'clock, a.m., I was sent for by Mr. Moore, resident pupil in the Belfast General Hospital, to see Mrs. L., whom he had brought into the house the night before. She had now reached the full period of pregnancy, and during the last three months she had been attacked frequently with profuse hæmorrhage. I found her very weak; pulse nearly gone. On examination discovered a complete placental presentation. The hæmorrhage continued. The child was found to be alive; but both mother and child were in extreme danger. She was placed under chloroform. I introduced my left hand, separated the posterior edge of the placenta from the uterus; passed onward; punctured the membranes, got a hold of the child's foot, turned, and brought away a living child. Although the mother had a severe attack of puerperal fever, both she and the baby did well. I was present when a member of this Society, in a case of placenta prævia, turned. His patient did well; but as I was only in the room, and did not make an examination, I am not in a position to say more.

I would conclude by stating that I know of no case in which the use of chloroform is more indicated, and in which the good results arising from it are so apparent, than when turning is practised.

Lastly, Dr. Simpson's statistics show that where turning is practised, there is a mortality of one in three and a-half, and consequently argues against it; whereas, I have brought under the notice of this Society six cases in which turning was the practice, and in some of them under very unpromising circumstances, with only one death, and which, I believe, was not to

be ascribed to the operation. I may add, that in this case, at her own request, chloroform was not administered.

{Rough minute book: Dr. Ross asked how would Dr. Dill act when the child was not viable.

Dr. M'Gee had seen three cases of placenta prævia and had once seen the placenta removed naturally before birth of the child. He always turned and the child had always been stillborn and the mothers had been saved.

Dr. Ferguson asked had Simpson more than 6 cases or what was the actual amount of his cases.

Mr. Johnston attended 1 case in which he got jaundice. He mentioned 1 case in which in the 7th month there was an enormous hæmorrhage. One day the membranes burst and pains commenced then enormous hæmorrhage cut in he turned and delivered. Both child and mother survived. Craniotomy had before been performed once twice child had been delivered by forceps.

Dr. Pirrie held that in partial presentations turning should not be adopted.

Dr. Heeney held that the hæmorrhage would be likely to be increased by the dilatation.

Dr. Patterson met partial placenta prævia often always with hæmorrhage and never had to turn.

Dr. Murray met one case in which he turned readily.

Mr. McCormac said it has been shown that the termination of the placenta vessels is by tufts dipping into veins.

The printed transactions to be sent to the editor of the "Dublin Hospital Gazette".}

Council Ordinary Meeting March 2nd 1859.

Present, the Secretary.

The circular prepared.

EIGHTEENTH MEETING.

March 5th, 1859.

{Rough minute book: President in the chair, Drs. Moore, Halliday, Murney, Patterson, M'Gee, Mulholland, Seaton Reid, Gordon, Arnold, Drennan, M'Cleery, Bryce, Rea, Ross, Dunlop, Johnston, Murray, Harkin, M'Minn.

Dr. Hodges proposed by Dr. Reid seconded by Dr. Mulholland.

The Treasurer Dr. Halliday had statement of a/cs. £24-5-3 in hand.

Dr. Gordon moved and Dr. Patterson seconded, That the words viz "Licentiate Apothecaries" ...

Dr. Gordon then gave notice that he would bring forward the subject at the annual meeting.

Mr. Browne introduced a woman in whom malignant disease had returned 3 years after operation unmarried 45 years of age.}

Foreign body in Bladder.

The PRESIDENT exhibited a piece of bone, two inches and one-eighth in length, thickly incrustated with phosphates, so as to make it one inch and a-half in circumference, which he had removed from the bladder of a male patient in the hospital that morning. The operation performed was that recommended by Mr. Allarton, and which had been recently adopted successfully by himself, in the case of stone which he had brought under the notice of the Society at the early part of this session.¹ The history of the case, he said, might be stated in a few words. The patient, a man of 50 years of age, looking now, however, much older, some few months since, while labouring under an extraordinary state of morbid feeling, had introduced into the urethra a pin of turned bone, a part of a crochets-needle handle, which, finally, had either slipped, or had been pushed into the bladder. From that time, of course, a good deal of suffering commenced, and continued to increase up to the period of his admission to the hospital, near the end of January last. During all the time he was under treatment he never divulged what he had done, save to the first surgeon whom he had consulted, and who told him that the foreign body could only be removed by some operative proceeding. Even after he was admitted into hospital, and when sounded for a calculus, which was suspected, he did not once mention the peculiar circumstances of his case; and it was only on Monday last that he hinted at the true nature of the exciting cause of his symptoms. On Wednesday Mr. Browne introduced a sound, and then believed he felt a foreign substance; but on Thursday, having injected the bladder with six ounces of tepid water, the body was easily detected lying in the left side of the base and near the neck of that viscus. An operation was then of course the only remedy for the poor man's most painful sufferings; and consequently, on Saturday, at ten o'clock, the patient was brought into the operating theatre, placed upon the table, and subjected to the influence of chloroform.

When he was fully under the effect of the anæsthetic, the bladder had six ounces of warm water injected into it, and the sound having been introduced, the foreign body was appreciable to the touch of the surgeons present. The sound having been withdrawn, and a No. 11 grooved staff having been substituted, the patient was secured in the usual position for lithotomy. Mr. Browne then introduced the index finger of the left hand into the rectum, so that its tip rested against and fixed the staff at the prostate. A

¹ [Page 730.]

straight sharp-pointed knife was then thrust into the centre of perinæum, half an inch anterior to the anus, and carried horizontally on till it struck the groove of the staff, immediately in front of the prostate gland. The membranous portion of the urethra having been divided, the knife was withdrawn, and the external wound was extended anteriorly towards the scrotum for an inch and a-half; the staff, it should be remarked, was held perpendicularly, and hooked up under the pubis. A long ball-pointed director was next passed along the staff; the staff was withdrawn, and the left index finger, well greased, was carried along and above the director with a slow rotatory dilating movement, till it entered the bladder, and the tip of it rested against the foreign substance, which lay obliquely across, and a little to the left side of the neck of the bladder, one point being firmly fixed in behind the prostate, and the other held in a fold of the mucous membrane of the anterior part, and it was only after repeated attempts that the points of the bone could be freed from the structure of the bladder in which they were imbedded, every application of the instruments proving fruitless, till Mr. Browne having pushed the upper point backwards with his finger, was enabled to seize the other with the forceps, and to extract the body exhibited. The bladder was then well washed out with warm water, the patient was removed to bed, and an opiate was exhibited. Some twenty-five minutes elapsed after the section of the bladder before the bone could be extracted.

The PRESIDENT concluded by observing, that from the long-continued irritation and injury of the bladder by the pointed body grasped by, or rather imbedded in, its structure, and from the great difficulty experienced in the extraction of the foreign substance, he considered the patient in imminent peril; however, what had been done was imperative, and as little injury was inflicted as, in the circumstances of the case, was possible.

{Rough minute book: Dr. Halliday had attended him for a month without learning whether he had passed a bone.

Dr. Murney had him in hospital but he had not learned whether he had passed ...}

Recent Parts in Case of Dysentery.

Dr. DRENNAN exhibited the transverse colon and rectum of a sailor, aged 32, who had died four days after admission to hospital, in an advanced stage of dysentery. The disease had commenced as diarrhœa, four months previously, after exposure in the Chinese seas to great vicissitudes of weather and temperature, and had been aggravated, he thought, on the voyage home, by unsuitable diet.

For the last month there had been copious discharges of blood, tenesmus, and general abdominal uneasiness on pressure. On admission he was in a

state of great prostration. Opium was freely given, and on the second day an enema, containing 1 scruple nit. arg. in 4 oz. of water, was administered, with an O'Beirne's tube, and repeated on the following day. Slight relief followed the first—no marked symptoms at either injection. He continued to sink, and for some hours before death, there was very frequent action of the bowels and hiccough.

The *post-mortem* examination (twelve hours after death) disclosed disease amounting almost to disorganisation of the greater part of large intestine. The descending colon gave way under the hand. The mucous membrane was extensively destroyed, and in several places the muscular coat also. About three inches above the anus a rounded aperture of more than half-an-inch in diameter, and with thinned edges, had given rise to an extravasation of fecal matter into the abdominal cavity. Some soft lymph coated the peritoneum around this opening. The stomach and small intestines seemed blanched; the liver not abnormal; the spleen contracted.

The practical conclusion drawn from the case was the necessity of great caution in administering enemata where such a state of the intestines as the foregoing might possibly exist. Whether or not the enema-pipe had in this instance caused the perforation, the state of the intestinal coat rendered such an accident, under the most careful management, far from improbable.

Case of Severe Injury.

Dr. W. MACCORMAC said—The following case is that of a man who was first knocked down and then run over by a heavy four-wheeled machine. When first seen, about twenty minutes subsequent to the occurrence of the accident, he presented the symptoms of extreme collapse, the pulse and breathing barely perceptible. He died a few minutes afterwards. On a *post-mortem* examination, the eighth, ninth, and tenth ribs of the left side were fractured, as also the left ulna. On being opened, the abdominal cavity seemed completely filled with blood. The superior surface of the liver presented two fissures, which had not quite divided the capsule. On the inferior surface in the portal region the substance of the organ was most extensively broken up and lacerated, while the portal vein was ruptured. The liver seems to have suffered in this instance from a species of *contre coup*, as the external injuries were all on the left side. As the cause of death—the object in view—was rendered quite apparent, no further examination was instituted.

The recent parts were exhibited.

Removal of Prepuce.

Dr. MOORE exhibited a prepuce which he had removed. The patient, he said, had injured the penis by the introduction of a rusty nail: inflammation had en-

sued, followed by ulceration, and the glans penis had protruded through an opening thus formed in the side of the prepuce. The larger part of the prepuce, accordingly, resembled a small supplemental penis at the side of the organ. Considering the inconvenience and unsightliness of such an appendage, he had deemed it advisable to remove it.

Artificial Arm.

Dr. MURNEY showed a highly ingenious artificial arm, made by Mr. Bigg, of London.

Council Ordinary Meeting March 9th 1859.

Present, the President, Dr. Cuming & the Secretary.
Circular prepared.

NINETEENTH MEETING.

12th March, 1859.

The Case of Foreign Body in the Bladder.

The PRESIDENT stated that the man on whom he had operated for the removal of the handle of a crochet-needle from the bladder, and whose case was before the Society at last meeting, had since died. He regretted his inability to procure an examination of the parts, but, from inspection of the foreign body, it was evident (about one-twelfth of an inch of each extremity being free from deposit) that the impaction must have been due to partial penetration of the walls of the bladder.

L'Estrange's Sound.

The PRESIDENT also exhibited L'Estrange's instrument for detecting and measuring calculi in the bladder.

Dr. ROSS eulogised this instrument, pointing to the advantage of the employment of the sense of hearing as well as feeling in discovering the presence, and, in a degree, the character, of vesical calculi.

Recent Parts in Case of Supposed Fatty Heart.

Professor REID exhibited to the Society some morbid parts, which were removed from the body of a patient who died recently in the Union Hospital. He said, the only portion of his previous history that I can give is, that his age was 62; that he walked into the car that conveyed him to the hospital, and also to his bed, from the chair upon which he had been carried from the bath-room; and then stated, that for the last two months "he had suffered from weakness only," and had slight dropsy of his feet and legs. He was very cold and pale, and on getting into bed, appeared quite exhausted and dying. Dry heat was immediately applied, and he was seen at once by the Resident Surgeon, who very properly gave him some whiskey in hot milk, and prescribed a cordial stimulating mix-

ture, with a sinapism over the chest. Soon afterwards he ceased to speak, although still conscious, and lay in a lethargic state all night, passing a considerable amount of urine in his bed; the bowels remaining quiet.

At my visit in the morning of the 1st inst., he was still cold and pale, opened his mouth when directed to do so, but did not speak. There was slight puffing of the cheeks during breathings, and occasional tremors or writhing movements about the shoulders and arms, such as are often seen to precede a fit of convulsions, or to follow an attack of apoplexy. He could move both arms and legs, which were rather emaciated, free from fat, and with little anasarca. The pupils were of equal size, and not dilated. The lower part of the abdomen was full, and dull on percussion, and on the catheter being passed, about three pints of urine were withdrawn, which was healthy in smell and appearance, free from albumen, and of sp. g. 1,013.

The respirations were regular, about 14 each minute, and the pulse in the radial artery 30 or 40. The veins on the temples, chest, arms, and legs were distended. No impulse was to be seen or felt in the region of the heart, and on applying the stethoscope over its base, a distinct cooing or musical murmur was heard, in place of the first sound; followed, after a short interval, by an indistinct second sound; this murmur was also heard in the sub-clavians and carotids, and very distinctly at the region of the apex. It was considered to be systolic, because it was heard immediately after the longest period of repose; although the pulse, at the wrist, was synchronous with the second sound. The radial and brachial arteries felt so full and firm, that I believed their coats to be atheromatous.

Interpreting the symptoms I have just enumerated, as indicative of fatty degeneration of the heart, I gave him at once four ounces of whiskey in hot punch, which was swallowed without much difficulty, but made no change in the frequency of the heart's action. The stimulating plan of treatment was continued during the next twenty-four hours, when, at my visits, I found his pulse to be 38, and of the same degree of fullness. The respirations increased to 18, and regular. He was now unable to swallow, and moaned often, which, with his lungs full of sonorous and mucous rales, rendered it quite impossible for me to ascertain the existence of either the musical murmur, or any sound of the heart; and, although the intercostal spaces were depressed, no impulse was either to be seen or felt. The tracheal rales increased during the evening, and he died at 2, a.m., on the 3rd instant.

Feeling much interest respecting the pathological state that existed in this case, I requested Dr. Murney to dissect for me the parts that had been removed by

Surgeon Rea, which he did with his usual courtesy and kindness. Mr. Rea, when removing the parts, found some fluid in both pleuræ; the lungs distended, and some old-standing adhesions in the left, and that no effusion existed in the pericardium. But that I was wrong in believing him to be the subject of fatty degeneration of the heart, is shown by the following statement of the morbid appearances:—The brain was found free from all indications of inflammation, effusion, or congestion, and was healthy in every part, except one or two specks of atheromatous deposit in the basilar artery. The heart was firm, of natural colour, retaining its natural shape and bulk, and having no disposition to collapse by its own weight. The valves of the aorta and pulmonary artery showed their sufficiency on the application of the hydrostatic test. The aorta, for several inches from its origin, was rough, owing to fatty degeneration, which, in some patches, had become atheromatous. On dividing the aortic orifice, we found a small ridge of soft vegetation on the ventricular surface of one of the valves—all the rest being healthy. A small fourth valve, in all respects complete, was observed at the pulmonic orifice. The walls of the left ventricle, as may be seen, are hypertrophied, being nearly an inch in thickness, and the cavity, if not contracted, is assuredly not dilated. Dr. Murney has examined it carefully with the microscope, and has found no indications of fat. The mitral valves were found healthy in structure, and the orifice natural. The brachial and radial arteries were free from any atheromatous deposit. The right kidney was found large and congested, but perfectly healthy in structure, while the left was found small, and in a state of fatty degeneration. There was no disease of the liver, spleen, or prostate gland.

Dr. Reid then said—Now, Mr. President, there are two points of interest in this case. 1st, Was it possible, under the circumstances I have stated, to have avoided this error in diagnosis? and, 2nd, How can the symptoms be explained?

To the first I reply, that the amount of information I obtained from what is called “the previous history of the patient,” was simply, “that he had suffered from weakness alone for two months;” and next, that the pulse continuing under 40 during the two days he was in hospital; the fulness of the radial artery; the first sound of the heart replaced by a murmur; the absence of all impulse to either sight or touch (not to be explained by pericardial effusion); the cold and pallid state of the body; the lethargic state, without paralysis, constituted a group of symptoms that might be considered almost pathognomonic of fatty degeneration of the heart.

To the second query I reply, that, to explain the feeble sound and absence of impulse in this patient, we have to remember that various writers on cardiac pathology have observed such to occur where the

ventricle was hypertrophied and contracted; but, should we agree with Cruveilhier and Budd that contraction cannot take place, we are absolutely certain that in this instance there was no dilatation. The cooing murmur that was present during the systole is sufficiently explained by the vegetation on the ventricular surface of one of the valves, and, perhaps, more satisfactorily by the roughened state of the first four inches of the aorta. The murmur being so distinctly heard at the apex, although the mitral orifice was healthy, must, I conceive, have been owing to the firmness of the substance of the heart rendering it a better conductor of sound. Dr. Bellingham states that this cooing, or musical murmur, is almost pathognomonic of regurgitant lesions of either the aortic or mitral valves.

This case, however, proves this opinion to be incorrect, because after a small opening was made into both ventricles, the water test proved that no regurgitation could take place at either the aortic or pulmonary orifice, and the mitral valve is to be seen perfectly healthy. The frequency of the murmur, and of the second sound of the heart when heard through the stethoscope, tallied so accurately with the number of pulsations at the wrist, that it is evident there could not, in this case, have been any of those practical and more frequent contractions of the ventricle that have been observed occasionally by others when the pulse was unusually slow. But of all the symptoms, it is perhaps most difficult, and, at the same time most interesting, to attempt an explanation of the relation that existed between the feeble action of the heart and slow pulse, and the lethargic or cerebral symptoms—or to decide in which of these organs was the first link of the morbid chain. We all know, that disease of the brain will undoubtedly diminish the frequency of the heart's action; and whilst Dr. Bellingham states “that the heart's sounds being slow, are more frequently due to disease of the nervous centre than of the heart;” yet he adds, “that fatty degeneration of the heart appears to be the only diseased state ever accompanied by diminution in the frequency of the heart's action.” Now, Dr. Murney, whose experience in examining this organ is unquestionable, is positive, after a most cautious and minute dissection of it, that it presented no evidence of any form or amount of disease, except one or two very small atheromatous deposits in the basilar artery. I believe, therefore, that the first link was furnished by the heart and aorta, and that the lethargic symptoms were due to the blood being sent into the brain in insufficient quantity and force; and that the inaction of the bladder was dependent on the depressed state of the brain; as the state of the prostate and urethra show that there was no impediment to the passage of the urine; while the natural thickness of the coats of the bladder, the smell of the urine, and its freedom

from mucus, prove that the bladder had not been habitually distended.

I should, perhaps, mention the absence in this patient of two symptoms, which are often associated with fatty heart; namely, the *arcus senilis* of Cauton, and the *respiratory distress* of Stokes—when these are present, they are valuable aids in diagnosis, but they may be absent, although fatty degeneration exists.

Professor GORDON, in allusion to the fourth pulmonary valve in the heart exhibited, said he never had seen such before, though he had seen a variety in the aortic valves. He also remarked that a pulse synchronous with the heart's second sound did not argue weakness of that organ.

Dr. MURNEY said he never had seen a variety in the number of the aortic valves, but he had before seen a fourth pulmonary valve. In relation to the symptoms in this case, he considered a distended radial artery and a firm pulse rather incompatible with the supposition of a fatty heart. He further said that the hypertrophied condition of the left ventricle was undoubtedly due to the obstruction offered to the circulation by the deposition on the semilunar valves and aorta.

Dr. ROSS was impressed with the idea, that this was a case of death from ureal poisoning, which supposition, independent of the symptoms detailed, he considered strengthened by the state and diminished size of the left kidney.

Dr. HEENEY asked if the spinal cord had been examined. He thought any inference as to the cause of death imperfect without an inspection of the whole nervous centres.

Professor REID stated, in reply to observations, that a distended state of the radial artery had repeatedly been observed in cases of fatty degeneration. The idea of its being a case of uræmic poisoning had not been overlooked by him; but, that when he found one kidney perfectly healthy, and shown by the catheter on two occasions to be capable of secreting 3 pints of urine daily, which was free from albumen, and of a sp. gr. of 1013, he could not satisfy his own mind, that there was any evidence, that a sufficient amount of urea was not eliminated from the system. He said the spinal cord had not been examined; and he further stated, that as the "Respiratory distress of Stokes" was a symptom that was not to be seen frequently, he would be happy to afford any member of the Society an opportunity of seeing it in a patient in the Union Hospital, in whom it was very well marked.

Case of Pemphigus Gangrenosus.

Dr. ROSS read the following case—

Catherine Kelly, aged four years, residing in a very contaminated atmosphere, was seen by me on the 20th of January, 1859. It was stated she had been about a week ill. Constitutionally there were febrile

symptoms, and locally, over the upper parts of the thighs, the lower portion of the abdomen, and the internal and external surfaces of the labia, and around the anus, there were several well-marked gangrenous ulcers and vesicles of pemphigus gangrenosus. Dysuria, and pain and tenderness of the affected parts were also present. As to the treatment, the chlorate of potash was given internally, and the nitric acid lotion was applied externally, with well-marked and immediate good effects.

On the 17th of February, 1859, the child was quite well, presenting no appearance of the attack she had passed through, with the exception of the cicatrices of the gangrenous ulcers.

Case of Anthrax in the Breast.

DR. MOORE exhibited a coloured cast of anthrax in the breast. The subject was a spare attenuated woman, aged 50. The case was unmistakably carbuncle, involving a portion of the mammary gland, and the line of demarcation was about to be formed. There was no interference beyond the application of a poultice, and the carbuncle sloughed out. He had never seen a similar case before, and from its rarity he considered it worth bringing before the Society.

Council Ordinary Meeting March 16th 1859.

Present, the Secretary.

Circular prepared.

TWENTIETH MEETING.

19th March, 1859.

{Rough minute book: President, Present, Drs. Halliday, Mulholland, Wales, Heene, Gordon, Ross, Reid, Ferguson, Patterson, Drennan, Dunlop, Warwick, Dill, Rea, M. M'Gee, Murray, Harkin, W. M'Cormac, Arnold, Johnston, Moore, Bryce.

Send back-reports to Maconchy.}

Professor FERGUSON laid before the Society two small bodies, resembling leaves in size and shape, which had passed from the bowels of a young woman, after a dose of castor oil. The patient had long suffered pain in the left hypochondrium, which had ceased since these substances had been passed.

Case of Polypus Uteri.

Mr. HARKIN read the following case:—

Margaret Devlin, aged 50 years, married, and mother of three children; her husband dead for 13 years; of spare anæmic habit, and melancholic temperament. Had enjoyed uninterrupted good health till within six years previous to my visit. At the commencement of that period, however, the menstrual

discharge ceased, and her health became much impaired.

For about four years, a copious and constant discharge of thin sanguineous looking fluid took place from the vagina, accompanied, at intervals, by what the patient described as “pure blood.” Cold and astringent injections were then used, which had the effect of putting an end to the discharge; but its disappearance was followed by severe attacks of pain in the hypogastric region, and general constitutional irritation, from which she very slowly recovered. After this time, she consulted several practitioners, who treated her for various diseases of the uterus, with little relief.

I was called to see her at eleven o'clock, p.m., on the 10th February, 1842,—the messenger stating that “the woman’s bowels had all come out.” I found her lying upon her back, her legs widely extended, and a large firm globular tumour, as large as a good sized turnip, protruding from the vagina. The tumour very much resembled an inverted uterus, and great difficulty was experienced in introducing the finger to make the necessary examination—the os externum being completely plugged by the tumour. The woman’s pulse was very feeble, her extremities cold, and the bedding was quite saturated with blood; I immediately administered a stimulant, which had the effect of rousing her from a state of syncope, and sent a messenger for Dr. Burden, who kindly favoured me with his advice.

After as careful an examination as was possible, and after obtaining from the patient the history of the case, we concluded that we had a pediculated polypus to deal with, attached to the os uteri; and determined upon its removal by means of the ligature and double canula. However, on grasping the tumour firmly for the purpose of passing the tube and ligature around it, the mass separated, the connecting fibres having given way, and without hæmorrhage or any other unfavourable symptom, the woman recovered.

The tumour weighed 1 lb. 9¼ oz.; its smaller circumference measured 11½ inches, its greater 15 inches. Upon cutting into its substance it appeared to be composed of fibro-cartilage, deposited in layers of a circular form, and white pearly colour.

The great point of interest in this case, irrespective of its unusual dimensions, was the difficulty which we met in making an exact diagnosis, and this applies to many uterine tumours; but the globular shape, the density and the weight of the tumour, and the absence of any trace of the fallopian tubes, and the history of the case which completely shut out any idea of its being an inverted uterus, decided our opinion. The converse, however, might occur, and it would be a sad misfortune, and one not at all unlikely to happen, to mistake an inverted uterus for a polypus, and not discover our error until it was too late to rectify it.

On Extra Capsular Fracture of Neck of Femur.

Professor GORDON read the the following paper:—

William Mitchell, aged 58, but apparently older, a pensioner, admitted into the Belfast General Hospital, February 12, 1859. He states that his habits are temperate, and also for some time past he has been subject to a chronic cough and shortness of breathing. On the evening previous to admission when passing along a dark lane, he was tripped by a rope, fell against the curbstone, and broke his thigh. On admission into hospital, the long splint was applied. On visiting him on the following day, there was no deformity, no shortening of the limb, nor complaint of pain in the thigh or hip.

15th—As the difficulty of breathing had increased, obliging him at intervals to assume the sitting posture, he removed the perineal band to be enabled to sit up. To permit him, therefore, to do so with greater facility and comfort, the long splint was taken off, and the limb placed on the double-inclined plane. This did not cause him pain, at least he made no complaint, nor was the fracture apparently disturbed.

16th—His expression is maniacal; he is talking incoherently. During the night he made several attempts to rise out of bed. The upper fragment of femur can be felt distinctly, about three inches below the trochanter major, causing the thigh at this part to be much bowed outwards. Measurement along the convexity does not show any shortening of the limb, but that of the concavity, or inner side of thigh, is shorter by two inches at least. Pulse 88, soft; skin moist; bowels open; tongue slightly furred; respiration 40. The limb was extended, and a pad and splint applied to the outer side of thigh, which was still kept on the double-inclined plane, and a broad piece of linen, with straps attached, was laid along the outer side of opposite thigh; some of the straps were carried behind, and others in front of the thigh, and being tied, prevented the outward displacement.

20th—Is becoming insensible; the forehead is covered with an abundant perspiration; pulse 108.

He died on the night of the 21st, or on the 9th day after the accident; and on the following day the femur was removed from the thigh; much blood was effused amongst the various tissues of the limb, even down to the knee. At first sight, the accident seemed to be a fracture of the upper third of the shaft of the femur, running obliquely upwards to the anterior part of the root of its neck; the capsular ligament attached to its end, preventing displacement upwards; but on removing this ligament, and the other soft parts adherent to the bone, it was found to be an extra-capsular fracture of the cervix femoris.

I exhibited at a former meeting of this Society this fracture, when the periosteum was on the cervix; then the line of fracture on the fore and upper part of the neck was so indistinct as to be incapable of detec-

tion, either by the sight or touch, and it was only by moving the fragments that the whole of its course could be traced. Now, however, when the parts have been boiled, we are able to perceive the full extent and true nature of the injury. The more carefully I studied the case, the more and more interesting it became, as affording us an example of extra-capsular fracture, which may have an influence in settling disputed points, by corroborating the views entertained by some, whilst at the same time it modifies, or is opposed to the statements or conjectures of others.

The fracture may be said to consist of four main fragments, in each of which may be included several minor ones.

The first consists of the head and neck. The second consists of the trochanter major; the posterior intertrochanteric line; part of the posterior surface of the lesser trochanter; and a triangular portion of the upper end of the shaft, which may be easily determined by a point on its external surface $3\frac{1}{4}$ inches below the base of the trochanters; and from the point thus indicated by drawing two other lines, one passing upwards and inwards, and ending where the base of trochanter joins the neck, the other, upwards and backwards to the lesser trochanter. We have thus a portion of the anterior external, and posterior surfaces of the shaft attached to the trochanter major, and posterior intertrochanteric line. The third portion consists of the lesser trochanter, and a small elongated triangular piece, running obliquely downwards and backwards to the *linea aspera*. The fourth portion consists of the remainder of the shaft.

Let us now trace the line of fracture. On looking downwards at the centre of the upper border of the trochanter, where the neck of the femur joins it, impaction commences. The fracture from this point runs obliquely downwards and backwards, internal to the *digital fossa*; after that it corresponds exactly to the junction of the neck with the posterior intertrochanteric line, and on reaching the upper and back part of the root of the lesser trochanter, it bifurcates, the posterior division running along the middle branch of the *linea aspera*, whilst the other branch runs above the lesser trochanter, separating it from the neck, and having gone forwards so as to be on a vertical plane anterior to the lesser trochanter, it again divides into a descending and ascending branch. The former running in front of the lesser trochanter, and passing obliquely downwards and backwards joins the branch behind it, or that which is in the middle branch of the *linea aspera*. Thus we have the lesser trochanter, with a triangular piece of bone attached to it, completely isolated. At the place where the fracture passes above the lesser trochanter, separating it from the neck, there were several comminuted pieces of bone. The fracture after that takes a course upwards and outwards along the inner bor-

der of the anterior intertrochanteric line as high as the base of trochanter. There the impaction ceases, the remainder of the fracture along the upper and anterior part of the root of the neck did not suffer the slightest displacement. Anteriorly, where the intertrochanteric line joins the trochanter, the fracture of the upper end of the shaft commences, whence it runs obliquely downwards and backwards, and joins that proceeding from the lesser trochanter, $3\frac{1}{4}$ inches below the base of the greater trochanter.

Besides these complete separations, we find partial fractures or fissures, which have, as I shall presently attempt to show, an important bearing on the mode by which fracture of the trochanter is produced. In the upper and external surface of the trochanter major there is a letter H like fissure, the upper limbs of which ascend over the upper border of the trochanter, and join the main fracture opposite to the commencement of the impaction, whilst the lower limbs pass half way down the trochanter. The extent of space within these vertical limbs is nearly one-third of the transverse breadth of the trochanter. There is also another fissure in the upper part of the posterior intertrochanteric ridge, which ends in posterior and superior angle of the greater trochanter.

Previously to the patient becoming delirious, I was fully satisfied with the statement made by our intelligent house pupil, Mr. Moore, that there was merely a fracture in the upper third of the femur; there was not the slightest appreciable deformity, nor did the patient make any complaint; and even when, in his delirium, he had disarranged the relation of the fractured surfaces, and even when I found the point of the lower end of the upper fragment displaced outwards $3\frac{1}{4}$ inches below the base of trochanter, the thought of the fracture being extra-capsular never occurred to me.

As the conclusions at which I have arrived from the study of this specimen of extra-capsular fracture are in several respects not in accordance with those of others, I shall first consider the question of shortening of the limb. Dr. Smith says, "From the opinion, therefore, of Rodet, that there may be no shortening of the limb in certain cases of fracture external to the capsule, I must altogether dissent...for in all such injuries there is impaction, and if so, there must inevitably be shortening of the limb, even though there be no loss of obliquity in the neck of the femur, no separation or displacement of the fractured trochanter, no laceration of the fibrous structure." (Smith on *Dislocations and Fractures*, pp. 18, 19). Now, the question at issue is this,—Is Dr. Smith right in maintaining that there is, in every instance of fracture of the neck of the femur, external to the capsule, a primary and immediate shortening, and Rodet wrong in supposing that when the trochanter and the fibrous tissue surrounding it is uninjured there is no shorten-

ing? I am fully sensible of the difficulty of giving a positive value to the precise signification of the term shortening. If by the words “primary and immediate shortening,” Dr. Smith means a shortening that can only be detected by the most accurate measurement,—a measurement that will detect shortening to the extent of a line, or a line and a half at the utmost,—then I should say that this specimen will corroborate his statements.

If, on the other hand, he means to imply a primary and immediate shortening, unequivocally capable of being detected in the living subject, and leaving no doubt on the mind of the surgeon that there is shortening, then I say that this specimen will not warrant such a positive statement. On the fore and upper part of the neck there is not the slightest displacement, and even behind and below at the base of the lesser trochanter, where the impaction is best marked, it is not more than a line and a half at the utmost. Now, is it possible that such a slight degree of impaction could cause a primary and immediate shortening capable of detection in the living? I think not. I am, therefore, bound to adopt the following inference, that this is an undoubted example of extra-capsular fracture, in which there was scarcely any eversion of the limb, and no shortening capable of being detected by the most accurate measurement. But, in addition to this, it presents us with an example of an extra-capsular impacted fracture, in which shortening might be referred to two different conditions of the same fracture.

The first, is that to which I have already referred, viz., the impaction of the neck of the femur. The second, is the oblique fracture through the shaft, which was produced in the following manner. When the lower part of the neck was driven into the shaft by the shock, it became wedged between the posterior part of the base of the lesser trochanter and the inner surface of the shaft, and instead of detaching the posterior part of base of the lesser trochanter and inferior part of posterior intertrochanteric line, it caused a very oblique and complete fracture of the shaft itself. Although anteriorly and internally the upper part of the shaft is detached from the base of the neck, almost as high as the anterior and internal part of the base of the greater trochanter, and after that running outwards and downwards for $3\frac{1}{2}$ inches, until it meets with that proceeding downwards from the lesser trochanter, still there was no displacement in the vertical direction, as the attachments of the capsular ligament in front, and the insertion of the gluteus maximus behind prevented it.

Another interesting question in connexion with this fracture is the *modus operandi* of the force causing it. With the first part of Dr. Smith’s explanation, I entirely agree, but the latter I cannot adopt. He says, (*Ibid*, p. 17) “What occurs appears, in fact, to be this—

the neck of the femur is, in the first instance, broken by the fall upon the hip, and then driven into the cancellated tissue, between the trochanters, by the weight of the body, and the prolonged action of the shock; but as soon as the neck of the bone is broken, the femur is rotated outwards, and even before the action of the first impulse has ceased. Thus the posterior intertrochanteric ridge being thrown forwards, is forcibly driven against the back of the neck of the femur; two forces, therefore, combine to produce the fracture through the intertrochanteric space, one of which consists in the impaction of the cervix into the shaft, whilst the other is found in the collision which takes place between the broken neck of the bone and the posterior intertrochanteric ridge.”

In this, and several other specimens in Queen’s College Museum, I do not find that the posterior intertrochanteric ridge lies in contact with the posterior surface of the neck, and, therefore, cannot admit that it is driven forcibly against the back of the neck, and produces the fracture through the trochanter; for if this were the case, would we not find the back of the neck lying against the ridge, and probably a depressed fracture in it? The fracture through the trochanter occurs antecedent to the impaction, and, therefore, antecedent to the inclination forwards of the posterior intertrochanteric ridge; and what seems to me to have occurred, and I think is capable of demonstration in the recent subject, was as follows:—the patient, on being tripped, fell upon the posterior and outer surface of the greater trochanter, which was, therefore, thrown inwards and forwards; the impulse, therefore, instead of being received equally on all parts of the base of the neck, fell, in the first instance, on its posterior part at its junction with the greater trochanter and posterior intertrochanteric ridge, which giving way, impaction occurred, and after that the remainder of the fracture.

The extent of the comminution and impaction will vary according to the fragility of the bone, and the amount of violence applied. The impaction of the neck will have unquestionably an influence in determining displacement of the trochanteric fragment; but, from the effects of blows on the trochanters, as witnessed on the dead body, the sequence of events seems to be as follows—direct lateral violence produces primary and immediate comminution of the trochanter, fracture of the base of the neck, impaction, additional fractures, and then displacement. Violence applied from behind forwards, produces primarily fracture and displacement inwards and forwards of the trochanter, impaction posteriorly, fracture of the base of the neck generally, and then displacement and fracture from the impaction. When the trochanter strikes the ground, it will be for the instant fixed, perhaps at this time, the extremity being in projectile force, acts obliquely, as a lever, in

breaking up the base of the neck. I think this specimen points to the impaction acting powerfully at two points, viz.—at the upper part of the neck corresponding to the prominent ridge which bounds superiorly the digital fossa.

It is at this part and a little in front of it, that the starting point of the fracture of the trochanter originates. The second point is, where the neck joins the lesser trochanter. There the compact tissue of the neck in expanding to form the lesser trochanter, is less thick than higher up, and when it gives way and enters the cancellated structure, it drives backwards the base of the posterior trochanter and the intertrochanteric ridge.

The impaction thus occurring simultaneously above and below, causes further detachment of the posterior part of the trochanter, even before the broken edge of the intertrochanteric ridge could possibly have come in contact with the posterior surface of the neck. Now, in this instance, the wedge-like action of the base of the neck at these two points, acting as it were differently, and instead of mutually contributing to detach the trochanter, have caused two different fractures. That above is the usual fissure or fracture of the trochanter; that below, instead of acting in a posterior direction on the lesser trochanter and posterior intertrochanteric ridge, has splintered the upper part of the shaft of the femur.

Council Ordinary Meeting March 23rd 1859.

Present, the President & Secretary.

Circular prepared.

TWENTY-FIRST MEETING.

26th March, 1859.

{Rough minute book: Present, the President, Drs. John Moore, Thomas Reade, Ross, Heenev, Seaton Reid, Warwick, Dunlop, Johnston, Ferguson, Hugh Rea, Mulholland, Patterson, Drennan, Moore, Halliday, Bryce, Murney, M'Gee (William), M'Cleery, Wales. Dr. Murray was balloted for and elected a member of the Society.

The President introduced a patient with recurrent scirrhus of lip. Dr. Thomas Reade opposed operation, also the President. Bryce and Ross favoured the operation as the glands of the neck were unaffected and as operations on cancer of lip promise more success than in most other sites.

Dr. Johnston introduced a case of tumour in parotid space. Browne Bryce and President considered strumous. Dr. J. wished to know the opinions of the Society as to its malignancy.}

Case of Injury of Head.

E. M., aged 20 years, was admitted into hospital on the evening of the 17th instant, from a severe injury of the head which he had just sustained. He stated that about an hour before admission, he had been spoking the fly-wheel of a steam-engine he was starting, while using considerable exertion, the wheel suddenly turned rapidly round, by which he was precipitated with great force into the wheel-pit, five feet deep, alighting on his head upon an irregularly paved surface. He at once recovered himself, and would have proceeded again to his work, had he not perceived that his face and neck were covered with blood. He was quite collected, not at all stunned, and walked a considerable distance to the hospital, to have his head dressed.

On examination, it was found that a portion of the skull at the anterior inferior angle of the left parietal bone was depressed beneath a lacerated wound of the integument, and that this piece of bone was about 1½ inches by 1¼ inches in extent. On further examination, this portion was seen to be actually stove in, and depressed fully half an inch. At the posterior inferior part of the same parietal, another fracture, to the extent of about half an inch, was found also to be deeply depressed.

Dr. MOORE, in my absence, saw the case, and very properly elevated and removed the depressed portions of the fractured bone; during this operation, and previous to the patient's arrival at the hospital, there was considerable hemorrhage from the torn branches of the meningeal artery. A dossil of lint was placed upon the bleeding vessel, and a light water dressing applied to the wounds. When I saw the patient at 9 o'clock, p.m., two hours after the receipt of the injury, he was perfectly conscious, and complained merely of the smarting of the cuts in his head. Pulse was then 86.

Early next morning I found he had rested tolerably well, and his bowels had been freely opened by the purgative and the enema, which had been exhibited; pulse 112. He told me he was "rightly," and felt little or no pain. On that day, about one o'clock, after he had exhibited some restlessness, he suddenly was seized with a convulsive attack, followed by unconsciousness, which lasted for about twenty minutes. When I saw him immediately after, he had recovered, and seemed calm and collected—pulse, 120; and he only exhibited some involuntary tremor of the limbs, and slight twitching of the muscles of the face. I had the dressings and dossil of lint removed, and directed cold applications to be constantly kept to the head. In the evening, I found him still quite intelligent, pulse, 126; he had, during the interval from my former visit, thrown off some bilious matter; and, I should remark, that he had had occasional vomiting from the period of his admission.

On the morning of the 19th, Saturday, I was informed that he had passed a fair night, and had vomited only once. He seemed unchanged, save that there was almost constant tremor of the voluntary muscles; he was perfectly conscious and capable of explaining his sensations; he complained of headache, but referred that to the wounds. On visiting him at five, p.m., I found that while he had not had any return of the convulsions of Friday, the muscular tremor had increased; and that, although he was evidently conscious, he could not speak or open his mouth to exhibit his tongue according to his desire, and yet, when requested to take some drink, he directly sat up and swallowed some milk and water. The following day, Sunday, he was dull and could barely articulate “no.” He also swallowed with difficulty, pulse, 126; breathing occasionally much hurried, but usually under 30 in the minute; pupils contracted; had strabismus of left eye; still he was evidently conscious when spoken to. That night he became violently delirious, and required restraint. Monday, the 21st, I found him restless, and incessantly straining his eyes in the attempt to look upwards, and to the left side. He had also an increase of that twinkling of the eyelids, that I have often seen in the last stage of fever, when fatal. From an early period, there was the muscular tremors and twitchings to which I have referred, but there never was sign of paralysis in any of his limbs; and the bladder and bowels acted naturally up till a short time before his dissolution. During the night, he gradually sank, and died without any return of the convulsions, at three, a.m., of the 22nd.

Post-mortem.—On removing the scalp, the site and extent of the injuries of the skull came into view. On the anterior inferior angle of the left parietal bone, an aperture to the extent of fully half-a-crown, and with comminuted edges, was exposed, within this the space was filled by a firm clot of blood. On the posterior inferior part of the left parietal an opening large enough to admit the end of the little finger was observed,—it was from this several small comminuted portions of bone had been removed. When the calvarium was removed, it was found that all around the edge of the large anterior fracture, the *dura mater* was separated to the extent of 1½ inches, fully, and was *bulged inwards* for more than half an inch, by a firm clot. On the inside of the posterior injury, the internal table was driven in to the extent of nearly a square inch, the *dura mater* also separated from the bone, but was not torn. When the brain was removed, the *dura mater* in the occipital fossæ, and in the right temporal fossa, was found to be detached and very easily separable.

The brain itself presented on the surface of the left hemisphere a considerable depression, corresponding to the part where the *dura mater* was detached, and bulged in by the clot of blood. The

arachnoid was very slightly opaque, and there was a small quantity of sub-arachnoid fluid. The cerebral mass, divested of the arachnoid, seemed paler than natural, and felt firm. On slicing the hemispheres the structure was found to be acutely congested—the vascular puncta being exceedingly numerous, the blood oozing from them in minute drops for some time after the division of these capillaries. The lateral ventricles were natural in appearance. The outer side of the posterior lobe of the cerebrum, at a point corresponding to the posterior fracture, had a portion, about the size of a small walnut, broken up, softened and infiltrated with blood, and, on the cerebellum, immediately adjoining this part, there was a bruised point, of the size of a field-bean. These were the lesions observed. There was not fracture of the base of skull.

Remarks.—The case briefly stated is one of those instances occasionally met with where the brain sustains a most severe and usually fatal injury, without any urgent symptoms being manifested at the outset; and is in striking contrast with others when an apparently trifling injury is attended by the most urgent immediate effects, and finally by fatal results—sometimes recovery. Here we had most extensive injuries, yet, as we have seen, the subjective signs were not manifested for some time, and then, indeed, very slowly. From the first, there had not been any symptoms of concussion, and, throughout the progress of the case, though there was considerable pressure on the brain, first by the depressed bone, and next by the effused clot, there was not any evidence of compression. The absence also of paralysis, was another striking feature in the case.

The *post-mortem* examination shews that the cause of death was the acute congestion of the entire brain, and the softening and effusion that occurred in the posterior part of the left hemisphere.

The remarkable vascular condition of the brain, (I refer to the multitude of bleeding points revealed by every slice that was made) I have only seen in cases of death resulting from yellow fever, and where head symptoms had prevailed, and when death took place very early in the disease.

{Rough minute book: Mr. Johnston exhibited a mass of uterine hydatids and read the history of the case.}

Council Ordinary Meeting March 30th 1859.

Present, Drs. Cuming & Wales.

Circular prepared.

TWENTY-SECOND MEETING.

2nd April, 1859.

{Rough minute book: President in the chair. Present, Dr. Ferguson, Arnold, William M'Gee, Heeney, Seaton

Reid, Johnston, Mulholland, Ross, Dunlop, Halliday, H. Rea, Wales, M'Cleery, T. Reade, M'Minn, Moore.

The President showed a flexor tendon which had been taken from a boy by machinery.}

Extirpation of Eye.

The PRESIDENT exhibited an eye, which he had removed that morning in consequence of long-continued irritative inflammation, and gave the following history of the case:—

J. S., aged 49, a mechanic, upwards of twenty years ago received an injury in his right eye, by a chip of iron having been projected against it with great force. A small portion of the metal was removed, immediately after, from the margin of the cornea, and gradually the eye recovered, so far as to be able to distinguish print, and to see small objects by the assistance of a glass. This state continued for some months, but at the end of a year and a half after the accident, vision was completely lost in that eye. During the subsequent ten years the injured eye gave no trouble: but since that time, it has been attacked, at intervals, with severe inflammation, during which attacks the patient suffered great agony, and, for the last four months, the distress has been so great as to incapacitate him for any employment. Under these circumstances, it was deemed advisable to remove the diseased globe. This was done while the patient was under the influence of chloroform; the conjunctiva was incised with a knife, and the curved scissors were then carried rapidly around the eye-ball, the muscles, optic nerve, and other attachments being divided close to it. There was not much hemorrhage, a little cold water and the infusion of matico sufficing to allay the bleeding; the part was dressed with a light compress of wetted lint and a bandage.

On laying open the eye-ball, it was found that all of the normal internal structure, with the exception of the choroid, had disappeared, and was replaced by a sepia-coloured fluid. The choroid was thickened, and adhered firmly to the sclerotica by layers of superimposed lymph, and the inner surface of the sclerotica, when these were peeled off, exhibited a beautiful rose tint. On washing the eye in a little water, a small piece of metal as large as a mustard seed was discovered: this was, doubtless, the cause of all the mischief that had ensued to the eye, and of all the patient's lengthened sufferings.

Diseased Mamma.

The PRESIDENT also brought under the notice of the Society a diseased breast, which he had excised a few hours before. The patient, a woman aged 82 years, *though looking much younger*, had always enjoyed excellent health till about three years since, when she had inflammation, and, as she described, likely sup-

uration of the left mammary gland. This abscess soon closed, and, for some eighteen months, it gave her no annoyance. About a year since, she felt a small tumour in the centre of the same breast. This gradually increased in size, till the entire gland became engaged, but without giving any pain. Two months ago a couple of vesicles appeared, one on either side of the nipple. These had been opened by a needle, and soon after a fungoid growth sprung forth, since which time the patient has felt a severe burning, shooting pain in the part. She was admitted into hospital on the 29th March, when the tumour was found to be about the size of the largest orange, of a deep puce colour, with many enlarged veins radiating over its surface. The site of the nipple was occupied by a pink fungoid growth, the size and shape of a large mushroom. This was covered by a smooth polished membrane, and was free from any sanious discharge. The tumour was quite moveable over the subjacent parts, though the integument adhered to the greater part of its circumference. The patient's health being good, the axillary and cervical glands being quite free from any disease; and, as her sufferings were daily increasing, it was resolved to remove the entire morbid mass. As it was feared that there would be profuse hemorrhage, it was deemed advisable not to add also the depressing effects of chloroform. Mr. Browne, therefore, determined to try the effects of local anæsthesia, and chose cold, with the view both of allaying the pain of cutting, and of avoiding the risk of profuse bleeding. Pounded ice, inclosed in a thin cloth, was therefore applied for about twenty-five minutes, when the integuments were found to be becoming white, and were insensible to the prick of a pin. A couple of sweeps and a few light touches of the bistoury sufficed, in five or six seconds, to remove the diseased structure. During the use of the knife the patient did not complain of any pain, and blood did not flow, but merely trickled forth for a brief period; the venous blood oozing out, thickened and very dark coloured. Cold and then tepid water was applied to the part, and, on the return of the circulation, three vessels were ligatured; the edges of the wound were brought together by three points of metallic suture, strips of dry lint and a compress, with bandage. In an hour after, smart hæmorrhage took place, which required the application of firm pressure and exposure for two hours.

This case, he considered, illustrated the benefit to be derived from cold as a local anæsthetic, where applicable, and where chloroform could not properly or safely be used.

A section of the tumour showed it to consist of a series of cysts in the glandular structure, surrounded by a capsule, as it were, of encephaloid deposit. These cysts at first seemed to be filled with colloid matter, but, on closer inspection, they were observed to con-

tain a straw-coloured fluid within the usual lining membrane.

{Rough minute book: Professor Ferguson lauded the application of cold.}

Uterine Hydatids.

Mr. JOHNSTON read the following particulars of a case attended by Dr. Hunter, Townsend Street:—

Sarah Molyneux, aged 21; married one year; four months advanced in pregnancy, as supposed; having menstruated last in November, 1858. Enjoyed good health till menstruation ceased; from that period has suffered much from sickness, without any positive ailment. On Wednesday, 16th inst., hurt herself pushing or lifting a large stone. Same evening was attacked with pains in the back and flooding, both continuing all night.

Dr. H. saw her on Thursday morning, and, finding the flooding slight, directed her to keep her bed, and gave her 30 drops every fourth hour of a mixture composed of three drachms of aromatic sulphuric acid and two drachms of laudanum. On Sunday morning, both hæmorrhage and pains had been absent for a considerable time, and neither returning till Thursday 24th, at eleven o'clock, p.m., the patient, in the meantime, expressing herself as very strong and well. Dr. H. saw her about half-past six o'clock on Friday morning. She had flooding and pains all night. On examining, found it difficult to make out more than the situation of the os uteri. The upper part of the vagina was filled with clots, very little escaping outwardly. The loss of blood evidently being by the accumulation of clots, which were expelled at intervals. Shortly after making an examination, a gush of fluid and clotted blood took place, and, judging from the hæmorrhage that it would be useless to arrest the threatened miscarriage, he plugged the vagina, applied cold, and gave ergot and borax. The pains becoming severe, he removed the plug for the purpose of examining, and found the os uteri sufficiently dilated to admit the point of the finger. On introducing the point of the finger, he felt a substance presenting—too firm for a clot and too rough for the membranes. On carefully examining, he came to the conclusion it was a case of placenta prævia, and sent for assistance. The patient getting low, he gave a stimulant, and the pains continuing, the plugging was forced out suddenly, and a large mass of hydatids appeared at the os externum, which was soon succeeded by another mass. The hæmorrhage ceased, and the patient afterwards progressed favourably.

Professor REID presented the following

Cases of Aneurism; With Remarks.

Having four cases of thoracic aneurism at present in the Union Hospital, in each of which there is some peculiarity in the symptoms, a few observations upon

them may be acceptable to the members of the Society.

I shall commence with one in which the presence of aneurism is rather a matter of inference than of proof. When thoracic aneurism has made its way into a locality where it can be seen and examined, its diagnosis is generally easy, and it loses somewhat of its interest. It is otherwise, however, when it is concealed from sight and touch, and when the symptoms it produces may, as in the present case, be caused by other kinds of tumor within the thorax.

This man, on admission, stated his age to be 37, but he looks at least fifteen years older. He has always been employed lifting and carrying heavy goods to his carts on the quay, and for several years past has been subject to cough, and pains about both shoulders, the latter of which often caused him to knock and press his shoulders against bags or posts in the shed, to obtain relief. These pains were felt at all times of the day, and he thinks they immediately disappeared on his putting on flannels; but has observed them to return "with a dart," if he left off the flannels for half an hour. He has never been intoxicated three times in his life, although generally taking stimulants daily, and has never had acute rheumatism. During the last eighteen months his cough and dyspnoea have increased, and the expectoration has been repeatedly mixed with blood.

About five months ago he entered an hospital in another town, and remained in it till a few weeks before entering the Union Hospital. During his entire stay there, he says that attempts were made, every few days, to pass a sponge saturated with a solution of caustic, through a tube, into his larynx, and that he believes this did him harm. He has often suffered from pain in his left ear on going to bed, which was immediately relieved by turning on his right side. There has never been any numbness felt in either arm, nor œdema of any part. He felt some difficulty in swallowing, for the first time, about ten days before admission, which required him to take his food in a softer state than usual. His bowels have been regular, and he has no difficulty in passing urine, which is of specific gravity 1,015, and free from albumen. He says he is much annoyed with flatulence in his stomach.

On admission to our hospital, he complained chiefly of the troublesome cough and dyspnoea, and pointed to the lower part of the trachea as the seat of all his ailments. His face was swollen, his cheeks (especially the left) flushed, his eyelids puffy, the conjunctivæ injected, and both pupils considerably, but equally dilated. There was some fulness at the base of the neck, and over the first bone of the sternum, and both jugulars were swollen. His voice was hoarse, and at times whispering. He had a loud, ringing, stridulous cough, the sound of which indicated that the cause of the stridor was situated low down in the trachea, or

behind upper part of sternum, and that it was an instance of Stokes, "stridor from below." His expectoration was composed of a viscid mucopurulent fluid, considerable in amount, and containing much florid blood. The right side of the chest was almost quite immoveable during respiration. When a finger was passed in behind the upper bone of the sternum, a rather hard and very indistinctly expanding tumor was to be felt, but no tumor or pulsation was to be felt or seen at any intercostal space at either side of the sternum.

When the hands were placed between the scapulæ, and over the sternum, no impulse was to be felt; but when I applied Dr. Green's test, of placing the chest in profile, a slightly heaving impulse was to be seen. The upper part of the right side of the chest, next the sternum, was duller on percussion than the same locality on the left. The stethoscope revealed, over the upper part, and to the right of the sternum, a distinct double sound and slight impulse, but no murmur. This double sound diminished in intensity as we approached the heart, the double sounds of which were feebler than those heard above; and no murmur was to be heard at either the aortic or mitral orifices, or in the subclavian or carotid arteries. A double sound is also heard from the occiput to the sixth dorsal vertebra, and between the spine and margin of right scapula, but no murmur. His pulse is 80, regular, and equal in both radials. At the apex of the right lung the natural respiratory murmur was replaced by a loud bronchial breathing or stridor, which was most distinct during expiration; and a similar condition existed behind. Lower down at the base a feeble respiratory murmur was heard, presenting thus a marked contrast to the puerile respiration heard over the entire of the left lung. His respirations are regular, about 24 each minute.

With such a group of symptoms, it is evident that the diagnosis lay between aneurism or the presence of some other tumor behind the sternum. The cough, the stridor, the double sound, the immobility of the side, the dysphagia and impulse, have all been produced by tumors that were not aneurismal, and therefore could not be relied on as diagnostic of an aneurism in this case, especially when he stated that one of his sisters had died of some form of cancer, although he was free from any external tumor.

There were, however, two circumstances connected with this man's history, which, associated with the symptoms I have just enumerated, warranted me, I believe, in deciding that he suffered from an aneurismal tumor. These were—first, that he always experienced relief from the pain in his left ear by turning on his right side; and the second is, that he now finds the cough, dyspnœa, and stridor so much relieved by lying on the right side, that he almost constantly assumes that position.

These two facts, I think, indicate that the tumor is moveable, to some extent, by its own weight, which could not likely occur were the tumor one of those that occasionally form in the mediastinum.

With respect to the portion of the aorta that is involved—whilst fully alive to the difficulty of deciding such a point, yet I believe, that the pains having been felt in both the shoulders, the stridor and other tracheal symptoms, the double sounds to be heard over the upper portion and to the right of the sternum, the immobility and change of the respiratory sounds, with dulness at apex of right side, all tend to indicate that it is the ascending portion, and chiefly the arch, that are implicated; but both pupils remaining of equal size, with no pulsation at any intercostal space, would, I think, justify the conclusion that the tumor, on either side of the medial line, cannot as yet be very large. This man has been in hospital for ten weeks, and his treatment has consisted in confinement to bed, a nutritious diet, with opiates, and regulation of the bowels. Under this plan almost all his symptoms have been relieved. The cough and stridor are greatly less, the blood has entirely disappeared from the sputa, and he has no difficulty whatever in swallowing; indeed he says he would be quite well, "were it not for the cough and the wind in his stomach." His appetite, he says, is good, but he is steadily emaciating since his admission, without there being any severe pain or waste of any kind to account for it. We might, therefore, infer that the tumor is pressing on the thoracic duct, and thus depriving him of nutriment.

SECOND CASE.

In the second patient, there is no doubt respecting the existence of an aneurism, but still there are some points of interest connected with his symptoms. His age is about 70. He has been several times a patient in the Union Hospital, in consequence of a troublesome cough and dyspnœa, with severe pains about his chest and shoulders, which were sometimes felt on the right side, and at other times on the left; but his intelligence is so much inferior to that of the last patient, that no great reliance can be placed on the accuracy of any history he would give. His employment was that of a turner of wood, and he admits that he lived rather freely.

On his last admission to the hospital, his voice had become so hoarse, and his cough had acquired that peculiar ringing and stridulous sound, that I suspected an aneurismal or other tumor to be the cause of all his sufferings and symptoms. I consequently made repeated examinations with reference to the presence of an aneurism, but failed in finding any symptoms of it, till about two months ago, when I detected a double sound over the upper part of the sternum, without any murmur. In a few weeks afterwards a

pulsation could be felt and seen between the second and third left intercostal spaces, where a double sound was now also to be heard, but without murmur. This double sound became feebler as we approached the heart, and markedly so at one spot. The sounds of the heart were feebler than those heard above, and there was no murmur at either the aortic or mitral orifices, or in the carotids. Soon afterwards a soft puffy tumor appeared above the left clavicle, and the jugular vein on that side was seen distended.

For some months past he has less power in his lower limbs than usual. At present his pulse is about 80, and regular, but feebler in the left radial artery than in the right; it is quite distinct in both carotids. His respirations are quiet and regular, his cough ringing and stridulous, its sound indicating that the cause of the stridor is below. Pressure behind the sternal notch does not reach any pulsating tumor. There is marked dulness at the upper part of the left side, where the double sounds are rendered more distinct by placing the patient erect; and pulsation is to be seen and felt between the third and fourth intercostal spaces, and as far outwards as a line perpendicular to the nipple. Pulsation is also to be felt, on deep and backward pressure, between the sterno-mastoid and trapezius muscles; and there is a distinct double sound between the edge of the left scapula and spine, but none along the spine itself. He has never had numbness or œdema of either of his arms, nor any difficulty in swallowing, nor expectoration of blood; nor is he now much troubled with cough. He says he can lie on either side, but I always find him lying on his left.

Both the pupils are contracted, but the left is permanently more so than the right; and this difference in size is still more marked when both are brought under the influence of belladonna. This contracted state of one pupil in aneurism was first recorded by Dr. Walshe, but a similar state had been described, in the *Medical Gazette* for 1838, to have been produced by a hard, but not aneurismal, tumor in the neck.

The merit of fixing the attention of physicians upon its frequent association with aneurism is due to Dr. Gairdner, of Edinburgh, and it is now invariably looked for in cases of that disease. Dr. Gairdner's first case, and an attempted explanation of its cause, led to a controversy in the *Edinburgh Medical Journal* for 1856, respecting the *modus operandi* of belladonna in producing dilatation of the pupil, to which, as the pupil is contracted in three of my patients, and that I had applied belladonna round all their eyes, I shall allude very briefly.

It is known that the iris is composed of circular and radiating fibres, the former of which contract, whilst the latter dilate, the pupil. It is stated that the circular fibres are supplied with nervous power from the third and also the fifth cerebral nerves, whilst the

radiating fibres receive filaments from the sympathetic, which joins the ophthalmic branch of the fifth, after it has passed through the Casserian ganglion; and that these filaments from the sympathetic derive a motor power from anterior roots of the spinal nerves in the lower cervical and upper dorsal region; and that division of the sympathetic in the neck, or of the anterior roots of the spinal nerves, causes the pupil to contract, by resigning it to the exclusive influence of the circular fibres supplied by the third. Now, it is known, that when the third nerve is destroyed, incomplete dilatation of the pupil takes place, and that a complete dilatation follows the application of belladonna to the eyebrows. It has, therefore, been asked, does belladonna cause dilatation of the pupil by paralysing the ciliary branches of the third pair, which supply the circular fibres, or does it act by exciting the motor filaments which join the fifth from the sympathetic and anterior roots of the spinal nerves, and thus stimulate the radiating fibres to contract, and thereby dilate the pupil?

It occurred to me, that as there was no evidence of disease of the brain in any of my patients with contracted pupils, that if I brought all their eyes under the influence of belladonna, the result might support one or other of the views in the foregoing question; for I thought that if belladonna acted solely by paralysing the third nerve, which supplied the circular fibres with motor power, its application to the eyebrows should be followed by an equal dilatation of all six pupils, as the radiating fibres in what we may call the aneurismal eyes would then have nothing to oppose their contraction. Equal dilatation, however, did not follow the application of the belladonna, for in each of the patients the contracted pupil, although dilating very considerably, was still markedly smaller than the other; nor have I been able to dilate it to the same extent as the sound eye by several days' application of the belladonna.

Now, it has been observed, that when disease or injury had paralysed the third nerve, complete dilatation of the pupil did not take place, but that it would do so if belladonna was subsequently applied; which would certainly imply that it had the power, by its action on the radiating fibres, to cause the latter to contract.

Dr. Benjamin Bell, of the Edinburgh Eye Infirmary, who advocates the stimulating theory of the action of belladonna, considers that in aneurismal cases the pupil is not fully dilated by it, because the circular fibres of the iris are then in unimpaired power, whilst the radiating fibres have their power of contraction impaired by the pressure of the aneurismal tumor, and that therefore the relative power of the circular fibres is increased. In one of the patients, whose freedom from suffering enabled me to observe the effects of belladonna more accurately and continuously, I

found that when it was applied equally to both eyelids, the sound eye was completely dilated, and the aneurismal one markedly less so; but when I applied the belladonna for several days around the latter, it dilated to a much greater extent than it had done at the period of the sound eye's full dilatation. Now, if the belladonna acted by paralysing the branches of the third, which supply the circular fibres, as there was no disease of the brain present to prevent its action, ought not the dilatation to have been as great, on the first day, in the one eye as in the other, and is it not therefore rational to suppose that the increased dilatation was due to the persevering stimulation by it of the partially paralysed radiating fibres? I therefore consider that the results that followed the application of the belladonna, in my cases, tend to support the accuracy of the opinion advanced by Dr. Bell. It is interesting to find, that in the case of aneurism in which the disease appears, for so far, to have chiefly implicated the arch of the aorta, the pupils are both rather dilated, and equally so; whilst in the three other cases, in which there is evidence of tumors on the side of the spine, the pupil is affected on the side where the tumor is; so that a contracted pupil, if it had been previously of natural size, might, in an obscure case, become an important sign of the presence of a tumor on the same side. And again, when both pupils are greatly contracted, as is the case in one of my patients, the application of belladonna would indicate the one that was so from the paralysing presence of a tumor.

As one pupil is occasionally smaller than the other, owing to previous inflammation in the iris, or some other cause, it will be necessary to bear this in mind, when looking for it as a symptom often present in aneurism.

In this man the aneurism appears to be enlarging very rapidly in the direction of the left thoracic cavity; but in consequence of its not coming in contact with any of the bones or nerves, it is really giving him little, if any, annoyance. Whilst in the former patient I considered that it was the ascending portion, and chiefly the arch of the aorta, that was involved, I think that the symptoms in this patient would indicate that it was the arch and descending portion of the thoracic aorta that is implicated.

My next two cases differ from those I have just noticed, in having, I believe, a different vessel in the thorax affected with aneurism; and in both of them there is much interest connected with some of their symptoms. One is a male, and the other a female.

THIRD CASE.

The male patient stated, on admission, that his age was 60, and that for the last six or seven years he has had pain in his right shoulder, and also in the neck of that side for about two years. No pain was felt on the

left side at any time. He suffered from dyspnoea since the pain in the neck appeared, but had no cough till within the last six months. During the last four days, only, has he had any difficulty in swallowing, and he thinks the food is stopped about the base of the neck.

He was able to lie on either side till twelve months ago; since then he was easiest on right, till within the last few days, when he requires to sit up; for if he lay down, he would perspire profusely from pain. He has never had œdema of any part, or any expectoration of blood, or any numbness or want of power in either arm. His urine has a specific gravity of 1,025, and is free from albumen. The sternal end of the right clavicle is dislocated by a pulsating tumor behind it, which is felt not to extend across the trachea, or into the sternal notch; but an apparent prolongation of it can be felt distinctly, deep in the neck, between the sterno-mastoid and trapezius muscles. No pulsation is to be felt or seen in any of the intercostal spaces, and that in the radial artery on the right side is feebler than in the left; it is distinct in both carotids. The right jugular vein is distended, but no puffiness about neck. His feet, knees, and hands are slightly livid, but free from œdema. His face is sallow, and lips pale. The right pupil is smaller than the left. A distinct double sound is to be heard at the top of the sternum and to the right of it, as also in the neck, and at the supra-spinous fossa. The heart's sounds are feeble, but distinct, with considerable pulsation in the epigastric region. No murmur is to be heard at either mitral or aortic orifice, or in the carotid arteries, or over any of the localities where the double sound is to be heard in the tumor. The respiratory murmur is less distinct at the right apex. His cough is troublesome, and the expectoration difficult; it is muco-purulent, and free from blood. The respirations are irregular in frequency, ranging from 40 to 50 at different periods of the same minute. His pulse is also irregular in frequency, ranging from 70 to 110, when counted at different portions of the same minute.

Next to deciding the site of the aneurism, the state of the respiration and pulse are the two symptoms to which, in this and the next case, I attach the chief interest, and to which I shall now allude.

For about the sixth of a minute there is perfect quietness and regularity in this man's breathing; then the respirations gradually increase in frequency and loudness, till they became so loud, especially during expiration, as to be heard several yards off, and so laboured, that every muscle appears to be acting to dilate the chest. Then the respirations become gradually less loud and less frequent, till they return to the state of quietness and regularity I have mentioned, when he will say, "Now I am quite well." After a few seconds of repose, the same process is commenced again; and this is continued, with more or less intensity, whether asleep or awake.

This man called this state “palpitation,” and said that it had annoyed him much for the last three months; but it is evidently an instance of what is called “the respiratory distress of Stokes.” The number of respirations would vary from 40 to 58 during a period of distress, and on other occasions from 32 to 37, when six or eight calm respirations will take place. This symptom is the cause of his greatest suffering, as he has now little, if any, pain or cough.

I have stated that his pulse was also irregular, which it is, if felt during a minute; but I found, on closer examination, that both in this man, and in the female whose case I have next to notice, there was a curious regularity to be observed in its irregularity. For example:—counting it during an entire minute, it would be about 90; but when it was counted from about what I may call the mid-way up of a paroxysm of respiratory distress to mid-way down of the same state, it would be found to number about 12, or at the rate of 70 in a minute; then it would rapidly increase to 17 or 20 in the next sixth of a minute; so that, if counted from that time till the “respiratory distress” was again mid-way up, it would be found beating at the rate of 120 or 130 in the minute; and this state of the pulse was found present from day to day.

The symptom of respiratory distress was first observed by Dr. Cheyne, in 1816, in a gentleman who suffered under fatty degeneration of the heart; and Dr. Stokes, who first directed the attention of the profession to it, states, “that he has never seen it except in examples of fatty heart.” I am not in a position to say that fatty degeneration does not exist in this man’s heart, but that he is the subject of aneurism there can be no doubt; and that it is the arteria innominata is involved, I am disposed to believe from the following reasons:

1st. There has been pain for years, confined exclusively to the right shoulder and neck. The sternal end of the right clavicle is dislocated by a pulsating tumor immediately behind it, which tumor is also to be felt higher up in the neck, at the edge of the trapezius muscle. The pupil of the right eye is smaller than that of the left. The right radial artery has a feebler pulsation than the left; and the double sounds are heard most distinctly at the right of the top of the sternum, and in the site of the tumor. Again, there has been no stridor or ringing cough; no pulsation in the centre of the sternal notch, or in any of the intercostal spaces. With respect to the peculiarity of the pulse I have mentioned, I have not been able to find, in any work on cardiac pathology, that the pulse had been observed to become invariably slow during the period that the respiratory distress was most severe, and again invariably quick when the distress was least, and, I might say, absent; and as this continued day after day, and was observed also in the female patient, I think it cannot be looked upon as a mere

accidental occurrence. It may, perhaps, be found by myself and others so frequently as to prove that there may be (to use an Irishism) a *regularly irregular* pulse as an associate of the respiratory distress.

This patient has now been in hospital for three weeks, and a marked amelioration of his sufferings has taken place. Within the first week he was able to lie down on his right side, with his head resting on his hand, and his elbow on the pillow. Now he is able to lie on his back, and occasionally, for a short time, on his left side. He has no difficulty in swallowing, and has little cough, and no stridor. The respiratory distress has almost entirely disappeared, his respirations being yesterday about 26 in the minute, and now, to a casual observer, partaking more of the character of sighing respiration than of the distress I have described, and which had been seen by several members of the Society during the past fortnight. The pulse has also become all but perfectly regular, and beats about 90 in the minute. This group of symptoms would, therefore, appear to be one that is not continuous in intensity, whatever may be its cause. Since its great diminution, I have observed that the thorax is now more shaken by the impulse of the aneurism, and the clavicle moved forward each time, and I fancy I observe it larger at the sternal notch; the relief to the distress may, therefore, be owing to the backward pressure of the aneurism being less.

FOURTH CASE.

My fourth and last case is that of a female, aged 59, who stated, on admission, that for five years past she had severe pain in her right shoulder and arm, which was always most severe at night. This pain continued till about three weeks ago, when it ceased entirely. She had also had numbness of right arm. She never had any pain or numbness in left arm.

About two years ago, she had an attack of epistaxis from the right nostril, and about that time vomited a considerable quantity of blood. For years she had been subject to a “winter cough,” which is, however, quite free from any stridor or ringing sound, and she is quite certain she never coughed up any blood. She has been a hard-working industrious woman, and ascribes the commencement of her illness to a severe fall. Her face is puffy, and there is also some anasarca of the lower limbs, and ascites, but no fulness about the base of the neck. The right pupil is contracted, being markedly smaller than the left, and this difference continues when both are brought under the influence of Belladonna. Both jugular veins are swollen, but there are no enlarged veins on the chest. There is no displacement of the clavicle, nor any pulsation to be felt behind the sternal notch, although she describes the tumor as being there, which she says she can push aside with her finger, and thus relieve a difficulty in swallowing that is occasionally,

but not always, present. An unusual pulsation is to be felt and seen about the inner third of the clavicle, and the carotid artery there feels dilated, as also an artery crossing towards the trapezius. An indistinctly pulsating tumor is felt deep at the back of the neck, between the sterno-mastoid and trapezius muscles. No pulsation is to be felt or seen at any of the intercostal spaces. Pulsation is distinct in both carotids, rather stronger in the right, and the pulse in the right radial artery is feebler than in the left. A distinct double sound is to be heard over the upper part and to the right of the sternum, and louder than at the left of it, or over the region of the heart. It is also heard over the supposed tumor in the neck, and between the scapula on both sides of the spine, but loudest on the right. The heart's sounds are distinct, especially the second, and its impulse is also to be felt. There is no murmur at either the aortic or mitral orifices, or in the subclavians or carotids, or at any of the localities where the double sound is heard. Since her admission, she has at times been able to lie on her back; but, generally, she is obliged to rest on her knees, with her face on the pillow, inclining a little to the left side. This position appears to increase the dropsy of the eyelids, face, and chest; the right mamma is greatly more swollen than the left, and to-day there is a large anasarca over the trachea and sternal end of right clavicle, and the ascites and anasarca of the lower limbs are increasing. The urine is acid, of sp. g. 1,020, and albuminous. I have already stated in my review of the symptoms of the last patient, that the "respiratory distress of Stokes" was present in this female also for the last two months; and that it was associated with precisely the same regular irregularity of the pulse. Resting the head with the face to the pillow, and lower than the trunk, is a position, described by Dr. Stokes, to have been assumed intentionally by some of his patients, who had fatty degeneration of the heart. Six days ago, this woman coughed up three or four sputa composed of blood and pus; and, during the next night, she states she vomited fully a pint of blood. Although the existence of a pulsating tumor could not be so certainly felt as in the last patient, yet the other symptoms present, and the history of her ailment, tallied so exactly with his, agreeing with him also in the absence of certain symptoms, that I am disposed to believe that the arteria innominata is also implicated here, with perhaps a portion of the aorta.

She is in every respect becoming so rapidly worse, that I believe her dissolution to be not far off. When noticing a contracted state of the pupil being present in three of my cases, I already mentioned that the tumor and contraction were on the same side. With respect to treatment—these two last patients have earnestly asked for stimulants, and have reported that they were greatly relieved by them; whilst the two in

whom the aorta appeared to be solely involved have shown no such craving for them.

{Rough minute book: (Dr. Maconchy, Mr. Murray (Lurgan), Dr. Hodges.)

Dublin Hospital Gazette.}

Council Ordinary Meeting April 6th 1859.

Present, the President.

Circular prepared.

TWENTY-THIRD MEETING.

9th April, 1859.

{Rough minute book: President in the chair. Present, Dr. Ferguson, Dill, Patterson, Wales, Rodd, Heeney, Seaton Reid, Murney, M'Cleery, O'Hare, Cuming, W. M'Gee, M'Minn, Murray, Moore, Mulholland, Warwick, Johnston, T. Reade.}

Cases of Aneurism Continued.

Professor REID exhibited the heart, large vessels, and kidneys of the female patient whose aneurismal symptoms had been described at the last meeting of the Society. For several days before death, she was so exhausted as to be compelled to assume the recumbent posture; and that in consequence, the dropsy of the face and eyelids, as also that of the greatly enlarged right mamma, had diminished very much; with, as might be expected, a corresponding increase in the size of the arms and legs. Her pulse had become more regular, and the right pupil had assumed the size of its fellow. Her death was quiet, and apparently from exhaustion.

He said:—Dr. Murney, with his characteristic courtesy, had made a *post mortem* examination which revealed, as will be seen from his report, fatty degeneration of an hypertrophied and dilated heart, Breschet's cylindrical aneurism of the aorta and innominata, effusion into both pleura and contracted and fatty kidneys, &c.

Dr. Murney found the body was emaciated; upper and lower limbs anasarca; and, on dissecting back the skin from the anterior regions of the neck, the external and anterior jugular and other superficial veins were found greatly distended. In the thorax a few unimportant pleuritic adhesions, and a considerable amount of effusion, were observed on both sides. The pneumogastric and phrenic nerves of both sides were traced to the lower part of the chest—the former from the middle, the latter from the lower, parts of the neck. No peculiarity was observed, nor did those trunks appear to have been subjected in any degree to pressure. The thyroid body was at least twice its normal size, and very firm. The subclavian, internal jugu-

lar, innominate and caval veins were greatly distended with fluid blood, without any clots. The ascending and transverse portions of the arch of the aorta were considerably dilated, but the descending portion and thoracic aorta were of normal calibre. The left carotid and subclavian arteries were also natural. The innominate, right carotid, and subclavian were a good deal enlarged, and the two latter were markedly different from the vessels of left side. The increase was, therefore, principally in the aorta and innominate, which latter was at least twice the usual calibre, and a minor degree of increase existed in the branches of this vessel.

Only two patches of atheromatous deposit could be felt externally, one at the upper part of the transverse portion of the arch, the other at the termination of the innominate; but when the vessels were laid open, a most copious deposit was found; it was as yet soft, and in no part, save those named above, had undergone calcareous degeneration; it varied from the size of a pin head to even larger than a split bean, in greatest quantity in the dilated vessels, but it also extended into those which did not exceed their natural dimensions. The right coronary artery showed the same diseased action in its coats. The heart was considerably enlarged and very greatly distended with blood, it completely filled the pericardium, and was from three to four times the natural size; large clots and fluid blood were found in each of the cavities: in the right auricle the coagulum was of the amber colour so frequently met with. Both ventricles having been opened, the hydrostatic test showed the perfect competency of the aortic and pulmonic semilunar valves. The wall of the left ventricle was 7-10ths of an inch in thickness; the cavity was very considerably dilated. The heart, with aorta, and other arteries referred to, weighed $20\frac{1}{2}$ oz. Deducting $2\frac{1}{2}$ ozs. for the vessels, will leave 18 oz. as the weight of the central organ of circulation. The firmness and colour of the muscular structure of the heart would not have indicated the existence of fatty degeneration, but microscopic examination showed the presence of a considerable amount of such disease. The liver, which seemed of normal size, was not removed. Both kidneys were small and firm, the right weighed 3 oz., the left $3\frac{3}{4}$ oz., both were highly congested, and had apparently undergone some degree of fatty degeneration; time, however, did not permit of a microscopic examination of their structure, but from the casual observation made, there seemed to be sufficient healthy material for the due formation of the renal secretion. A small abscess existed at the lower portion of the left kidney, situated between the fibrous coat and the secreting structure of the gland, but not communicating with its interior.

Dr. Reid being anxious to let the members of the Society see the morbid parts as nearly as possible in

the state in which they were found, the vessels had not been at first opened, and, therefore, as already stated, only two patches of atheromatous disease could be felt externally, one at the upper part of the transverse portion of the arch, the other at the termination of the innominate; but when the vessels were laid open in the presence of the members of the Society, a most copious deposit was found; it was as yet soft, and in no part, save those named above, had undergone calcareous degeneration; it varied from the size of a pin head to even larger than a split bean, in greatest quantity in the dilated vessels, but it also extended into those which did not exceed their natural dimensions. The right coronary artery showed the same diseased action in its coats.

He then said, I have no doubt Mr. President, that those members of the Society who were acquainted with the literature of aneurism, and who have followed my description of the symptoms present in these several cases, will have observed that in forming my diagnosis I have been chiefly guided by the information derived from the researches of the late Dr. Greene, and also from the labours of Dr. Stokes; and from an able memoir by the late Dr. Holland, of Cork, in which he has carefully compared the symptoms present in Dr. Greene's cases of aneurism of the arch of the aorta, with those reported by various writers to have been observed in 24 cases of aneurism of the arteria innominata. From this comparison, Dr. Holland deduced the following rule:—"That the symptoms and signs of innominate aneurism have a tendency to occur on the right side of the body; whilst those of the transverse portion of the arch, as shown by Dr. Greene's cases, appear on the left."

Having read the abstract he gave of the 24 cases, I considered he was justified in proposing the rule I have just quoted as being applicable at least to aneurism of the arteria innominata; and it was on this rule that I based the opinion that in the woman who has since died, "the arteria innominata and perhaps the aorta was involved." In her case the diagnosis was far more difficult than in any of the others, owing to the absence of unequivocal tumor and pulsation; yet the *post-mortem* examination shows how much we may rely on Dr. Holland's rule, when meeting with a similar group of symptoms.

I shall briefly review those symptoms, as now interpreted by the *post-mortem* examination.

1. There was pain felt exclusively in the right shoulder and arm for several years. Now, pain I believe is one of the earliest, most constant, and, perhaps, most frequent symptom of aneurism. But what is its cause? I believe the majority of us associate with its presence the idea of pressure by a tumor on the nerves, or other tissues in its vicinity. But in this woman, although pain was felt during five long years, yet the *post-mortem* examination showed, that in her

there was no circumscribed tumor to produce pressure, and that the enlargement of the aorta and innominate, were only to such an extent as we can readily imagine must be the case when all aneurisms are commencing; at which stage pain is almost invariably present, although tumor to any extent cannot as yet exist.

It therefore seems to me that the cause of the pain is owing to the enlarging vessels stretching the filaments of the nerves that surround it, and this view I conceive receives support from the state of the aneurismal parts in this case, in which the disease has taken the form of an equal dilatation of the vessels for several inches, to which the name of cylindrical or fusiform aneurism has been given, and in which a sack or tumor does not exist, to produce pointed pressure on the surrounding parts.

2. Next, there was some fulness and pulsation at sternal end of the right clavicle; whilst nothing similar was to be seen or felt on the left side.

3. There were the double sounds heard in the same locality, and behind; no doubt conveyed to the latter locality by the vertebræ. During life, I thought these were produced behind by what I considered was a pulsating tumor at edge of the trapezius muscle; but no such tumor was found after death, and I cannot satisfactorily account for my mistake, unless it was owing to the transversalis humeri artery arising, as it did, much nearer the axillary artery, and being, therefore, obliged to cross the locality where I felt this pulsation. It was the three foregoing circumstances that caused me to form the diagnosis I have stated.

4. With respect to some of the other symptoms that were present, I would remark, that we learn from the *post-mortem* examination that a large tumor is not necessarily present when the pupil on the same side is contracted, and that the current of motor power from the spinal nerves to the radiating fibres may be interfered with by a moderate dilatation of the aorta and innominate.

5. The microscopic examination of the heart supports the opinion of Dr. Stokes, that a connection exists between the symptoms of "respiratory distress" and a fatty heart. Had it not been for the microscope, this degeneration of the muscular fibres of the heart could not have been discovered in this case, as we had no other proof of its existence. The craving for stimulants in my two patients who had the respiratory distress, and who felt relief from their use, might be an indication of this enfeebled power of the heart, and of the propriety and safety of their use in similar cases.

6. I did not detect the effusion into the pleuræ during life; and cannot, therefore, say how long it was in existence; but having examined the right lung about a week previously, to ascertain if the aneuris-

mal symptoms might not be caused by cancer of the lung,

I think if the effusion had then been in existence, it would not have escaped my notice, as I examined the base of the lung on that side. I am therefore disposed to believe, that this effusion took place within the last few days; this, however, can be but a matter of opinion, because I was so much on the alert for aneurismal symptoms, that the others might have escaped my notice.

7. Unless we admit, that the right vena innominate was compressed by the dilated artery, nothing was found to explain the extraordinary œdematous state of the right mamma—extraordinary because she generally rested on the left elbow. That such was the cause is rendered probable by the fact, that the enlargement of the breast almost entirely disappeared, as soon as the patient was forced by debility to assume the recumbent position, and thus take off the pressure of the artery on the anterior wall of the chest.

8. I have next to notice the state of the kidneys, which, as may be observed, were much smaller than natural; but as their secreting structure was not much impaired, and as the urine on several occasions was of high specific gravity, I am disposed to believe that the albumen, in this case, was due to impeded circulation, rather than to a disorganized condition of these organs.

9. It only remains for me to allude to the statement of the patient, that she felt, and was able to push aside with her finger, a tumor at the sternal notch; I am disposed to hazard as an explanation of this, that the arteria innominate did occasionally approach too near the trachea, and that she was then enabled, by pressing her finger in behind the sternum, to push it a little aside.

Postscript.—The first of the foregoing cases died on the 22nd May, after two or three days' suffering from increased stridor, dyspnoea, and much increase of lividity. *Post-mortem* examination refused.

The second patient died suddenly on the 30th June, without any suffering; a small quantity of blood being found on his pillow. On *post-mortem* examination the left lung was found adhering to the aneurism, with a rent in it and in the pleura, through which a large amount of blood had been effused into the cavity of the latter. The parts were removed for a more minute examination by Dr. Murney, who kindly furnished the following report:

Heart normal, 9 ounces in weight; the walls of usual thickness, except those of the left ventricle, which were slightly hypertrophied. The aortic and pulmonic valves were healthy and competent. The ascending aorta was of greater calibre than usual; patches of atheromatous and calcareous deposit were found along it, at the origins of the three great vessels

and also on the descending aorta, which were the only parts submitted to me. None of these patches were large. An irregular-shaped opening, which would readily have admitted the extremities of three fingers, was found leading from the convexity of the aorta to the left side of the left subclavian trunk, opposite the ligamentous remains of the ductus arteriosus. It opened into an aneurismal sac, about the size of a cocoa-nut, which rested across the spine, almost symmetrically, being somewhat more prominent to the left side; in appearance it was not unlike a small double hydrocele.

In its general expansion forwards and laterally, the areolar tissue had been spread out into an innumerable series of layers of fascia. On its anterior surface, rather to the left side, a jagged irregular opening communicated with the interior of the aneurism. To this part the left pleura had been adherent, and on the giving way of the tumor, the membrane had also burst, permitting the hæmorrhage which preceded death. Behind there was no such protection, as the vertebræ, &c., were in direct contact with the stratified layers of coagula. Pressure had caused the removal of nearly the entire thickness of the bodies of the second, third, fourth, fifth, and upper part of sixth dorsal vertebræ; the heads of the ribs corresponding to these bones, on both sides, were also partially eroded; that of the fifth, on left side, was entirely destroyed.

The trachea, œsophagus, and other parts which must have been more or less displaced or compressed, had been removed when the *post-mortem* was held; I cannot therefore speak of the effects produced by the aneurism on those structures.

The *third* case died on the 4th May, after several days' severe suffering. Very great œdema appeared in region of right mamma (as in the fourth case), followed by œdema of right arm, and base of right side of neck. Considerable puffiness also appeared over sternum, with much lividity everywhere during last 48 hours. The symptoms connected with the respiration and the pulse rendered a *post-mortem* examination most desirable, and every influence was brought to bear to obtain one, but without success.

Case of Chlorosis.

Professor REID then added—It may be in the recollection of the Society, that at our meeting of the 5th February, I made a communication to them respecting the symptoms that were present in a girl, who was suffering from chlorosis,¹ in the Union Hospital. I then mentioned, that the reason for my bringing her case before the Society was, that a murmur was heard at the apex of her heart, in addition to the basic murmurs usually present in chlorosis. As soon as I had

observed this unusual murmur, I asked several members of the Society to examine her, in order that the accuracy of my observation might be confirmed or not. You alone, Mr. President, had done so, when I made my communication to the Society, and you were satisfied that a murmur was present at both base and apex.

Professor Ferguson visited her a few days afterwards, and also had no doubt that both murmurs were present; although treatment had even then been beneficial to her. At the period of his visit she was suffering from an inflammatory attack of her left lung, chiefly affecting the apex; and, I feared she might, like many other chlorotic girls, be passing into phthisis. I am happy to say that the attack passed off without any injurious results, and her lungs appear now to be perfectly healthy. Her general health has since then been rapidly improving. All the uncomfortable head and chest symptoms have disappeared; her colour and strength are vastly improved; and her general stamina so much increased, that the catamenia have reappeared.

When Dr. Ferguson was in the hospital last week, seeing some aneurismal patients, I asked him to examine her again, when he agreed with me that the murmurs had disappeared from both localities. It will be recollected, that I had heard a murmur at the apex of the heart, in the patient whose hypertrophied heart I exhibited here two weeks ago; and which, during life, I had thought was the subject of fatty degeneration; and that the mitral orifice and valves were found healthy in that heart. That case, and the one whose history I now complete, tend to confirm the opinion of Dr. Stokes, that a systolic murmur at the apex is not necessarily a proof of organic disease of the mitral orifice or valves, in opposition to the opinions of those authors whose views I formerly quoted in connection with this case of chlorosis.

Council Special Meeting April 13th 1859.

Present, the President in the chair Drs. Moore, Patterson, Bryce, Heeney, Halliday & Wales.

Carpenter's a/c 18/9 for repairing glass case was ordered to be paid.

Moved by Dr. Murney seconded by Dr. Patterson "That a circular requiring payment of annual subscription be issued by the Treasurer, and that those whose subscription remain unpaid after Saturday will be ineligible to vote at the ensuing election of officers."

A meeting of Council was ordered for Saturday after the weekly meeting notice of which was to be inserted in the circular.

A proof of voting papers was ordered to be submitted to Council at next meeting.

The weekly circular was prepared.

¹ [Page 766.]

TWENTY-FOURTH MEETING.

16th April, 1859.

{Rough minute book: President, Drs. Gordon, Ferguson, Patterson, M'Minn. Mulholland, Drennan, R. Stewart, O'Hare, Arnold, Ross, Halliday, Murney, Wales, & Cuming, Moore, Martin.}

Scirrhus of Mamma.

Dr. O'HARE read the following case, and exhibited specimen.—The subject of this disease was a lady, aged 50 years, unmarried; had ceased menstruating for the last seven years; had always enjoyed pretty good health up till seven months ago, when she complained of shooting pains through her left breast and shoulder. About this time I was called in to treat her for a very prolonged attack of gastric fever, which seemed to resist all the treatment I could devise. However, she got well, and at that time she noticed a small hardened tumour in the left mammary gland, in the seat of the darting pain, which never subsided, At this time it was not larger than a small split pea, and very hard. This was in Nov., one month after the gastric fever had subsided.

I lost sight of her up till six weeks ago, when I was asked to visit and treat her for an attack of bronchitis, and, upon examining her chest with the stethoscope, I detected a tumour the size of a hen's egg, which I at once believed to be cancerous, and advised its removal. To this she readily agreed, not, however, until I would first acquaint her friend, who is a surgeon of standing in the West of Ireland, He at once gave it as his opinion that the tumour should be removed, and seemed to be quite prepared for something of the kind, inasmuch as four sisters out of six of the family had cancer. The four, he said, had been unmarried; the other two had been married, and had large families, and always enjoyed excellent health, free from all appearance of cancerous degeneration, apparently, though beyond 50 years of age. He operated on two of the four alluded to, both of whom died within the three succeeding years of the operations. The third went up to Dublin, and was there operated upon by Mr. Cusack, of Steeven's Hospital, about two years ago, and still enjoys good health, without any apparent return of the disease. The fourth and last sister I operated upon on Tuesday last, who is now recovering rapidly. The wound is almost entirely healed, and on the whole, the operation appears to be successful.

The only feature in this case, Mr. President, in my mind, worthy of note, is the tendency in certain members of the same family to cancerous degeneration, and still more, in the unmarried portion of that family. It would appear to me that married life in the female is a prophylactic, to a certain extent, to cancerous degeneration.

The appearance of the tumour under the microscope warrants the operation, if operations in this disease be warrantable. Under a power of 450 degrees, the granular cells are very well marked, containing nuclei and nucleoli. A few caudate cells appeared, but not well marked. Upon the application of acetic acid, the cells still appeared more distinct.

Cancerous Growth.

The PRESIDENT exhibited a scirrhus tumour which he had removed from a female, aged 60 years, that morning. This growth was unconnected with the mammary gland, though in its immediate neighbourhood, being situated two inches behind the breast, and exactly below the axilla. He stated that he had seen three cases of cancerous growths occurring in the like situation, which very soon invaded the mamma. In two, the parts had been entirely removed by the knife, but the disease returned, and proved fatal within three years. One had advanced so far as to forbid any operation. In the case before the Society, he hoped the very early removal of the growth would be followed by permanent benefit.

Local anæsthesia had been produced by congelation. The patient did not suffer pain; but, in some time after, there was, as in the former case he related where cold had been applied, very smart hæmorrhage.

In the discussion which followed, some members attributed the bleeding to the active reaction after the congelation, others considered it was accidental, and that by a coincidence both of the growths had been freely supplied with blood-vessels.

The President promised to investigate the question farther, upon suitable opportunities offering.

Cystic Tumour Developed in Nævus.

Dr. GORDON read as follows:—

Mrs. P., aged 39, the wife of a respectable farmer, came to me on the 23rd of March, 1859, fully determined to have a wen removed, which, for the last six months, had caused her great pain and mental anxiety. On examination, I found on the left side of head, posteriorly, a tumour of the size of a turkey's egg. Its surface at several points, was of a livid red colour, and prominent, elsewhere it was unequally lobulated, firm to the touch, quite moveable on the parts beneath, and not very painful on being handled. Supposing it to be an ordinary cystic tumour, in which suppuration had taken place, and which would soon ulcerate, I felt no hesitation in assenting to its removal. Having procured the assistance of Mr. Moore, one of the resident pupils of the General Hospital, I proceeded to its removal—the patient lying on a sofa, with the head resting on one of its ends. As the scalp on the most prominent part of the swelling was very much thinned and discoloured, I determined to leave an ellipti-

cal portion of it attached to the tumour, of about 2½ inches in length and one in breadth.

The first cut, which was made rapidly, went through the skin, and about a line into the tumour. Hæmorrhage most profuse, in fact alarmingly profuse, and to a degree which I had never before witnessed, followed, not only from the vessels of the divided integument, but also from the tumour itself, preventing them being seen and tied. A sponge was pressed into the wound, and pressure made on it and around the tumour. I now requested Dr. Murney's assistance, who arrived in a very few minutes. In the meantime, the patient became faint, the hæmorrhage having ceased, partly from the weakness, and partly from the pressure around the tumour. A second incision was made as rapidly as the first, but the stimulus of the knife aroused the patient and the hæmorrhage. With my fingers the tumour was almost instantly raised from its bed, and the remaining connections separated by a few strokes of the knife. Three arteries were secured by ligatures, and yet the hæmorrhage was profuse from numerous small vessels. A compress of lint was placed in the wound, and the scalp brought partially over it, and then a second compress and a tolerably firm bandage restricted any farther loss of blood. Nine hours afterwards, the compresses and a small piece of the tumour which became detached during its evulsion, were removed. The edges of the wound were approximated, and the water dressings and bandage applied. During the day, the patient was weak, and the stomach irritable; but, on the next morning, she had recovered sufficiently to be able to go home, a distance of 12 miles.

The history given by the patient herself was as follows—She first observed the tumour when nine years of age, and, after gradually increasing in size for several years, it was punctured; suppuration supervened and continued for two years. In 1848 she married. Then it was about the size of a large pea; after that it gradually increased, until two years ago it was as large as a hen's egg. During the last six months it was the seat of constant and severe pain, which rendered her existence miserable.

On examination, the tumour was found to be invested by a thin fibro-cellular capsule, oval in shape, and made up of lobes or cysts. On making an incision into it, the knife, as it were, grated through it; and, on passing my finger along the cut surfaces, they felt rough, and this roughness was due to a large quantity of calcareous matter embedded in numerous small cysts. My first impression was that the tumour was sebaceous, which had undergone calcareous and malignant degeneration. But on examining it more carefully, with the object of determining the source of the hæmorrhage referable to itself, I found it bore an exact resemblance to those cases of cystic tumours developed in nævi, and which have been described by

Mr. Lawrence, in the 22nd volume of the *Medical Times*.

There are two cysts, sufficiently large to admit the point of the finger, which contained blood alone; these communicated with several others, and with a large vessel divided in the first incision. There are several other cysts, one of them of the size of a large filbert, in which there was a slightly yellow serous fluid and a quantity of fibrine; a third set, of which the main bulk of the tumour consists, are entirely filled with cholesterine, granular or molecular matter, free, or irregularly aggregated, resembling corpuscles, and a paste-like or nodulated calcareous matter.

I shall now relate one of the cases of Mr. Lawrence, with a few of his observations, which will show the close similarity of his cases and that now under consideration. There is, however, this difference, that in none of Mr. Lawrence's cases was calcareous matter present; but I regard this as denoting merely a more advanced condition of the same disease. "In the autumn of 1848, I removed from the chest of a child two years of age, a small tumour, partly solid and partly vascular. It had ceased to enlarge at the circumference, but the vessels, tortuous and with thinned walls, were becoming more prominent, and assuming the form of cysts. Upon examination after extirpation, it was found to be composed of veins, which, after pursuing a short course, became much dilated, and eventually formed cysts. In many situations the continuity with the vessel was completely cut off. The more recent cysts contained nearly pure blood; others contained a yellowish fluid, composed of fibrine, albumen, and altered blood-discs, mixed with a large proportion of water. The older cysts contained a limpid fluid, composed of water, albumen, granular matter, and cholesterine. In all the cases of cystic tumour now brought under your notice, the disease was either congenital, or of so long duration, that the patient could not remember its commencement. In this respect they resemble nævi. The smooth internal surface of the cysts in the three first cases, was more like that of veins than any other structure, while their firm texture, irregular dilatations, and partial constructions presented just such an appearance as might have been expected in veins which had undergone dilatation, and then lost their connection with the corresponding trunks. The venous origin thus assigned to these cysts is not an explanation of mine; *non meus his sermo*. I merely set before you the conclusions deduced by Mr. Coote, whose industry and accuracy you are well acquainted with, from a careful examination of the parts removed in the cases now related."—*Medical Times*, Vol. 22, p. 561.

Scirrhus of the Pylorus.

Dr. MURNEY exhibited specimen of scirrhus of the pylorus, which he had met with in the dissecting room.

Worms in General, and Tænia in Particular.

Dr. ROSS exhibited specimen of tænia, and read as follows.—While some are inclined to overrate the constitutional injury and disturbance produced by worms in the alimentary canal, others, I have no doubt, under-rate the effects they cause. If the ova of worms are ingested, in proportion as the system is below par, there will be a tendency to their growth and reproduction. A favourable nidus, and the introduction of the parasites into the body, are the general conditions of their existence in man. The most practical and useful view to take of the entozoa, is to consider them a complication of a deranged state of the constitution and of the alimentary canal, and that while we hold it to be of primary importance to improve the general health, we have a secondary affection, as in many other cases, requiring special treatment. For the expulsion of the whole tapeworm, I place most confidence in the oil of the male fern. The efficacy of oil and turpentine, however, is un-questionable, as the following case will show—

A girl aged 7, was “fat and lusty” until March 8th, 1859. For the two weeks succeeding this date, her general symptoms were feverishness, thirst, headache, severe umbilical pain, diarrhœa, and cough. Her food was porridge, potatoes, and bread, and her residence was in a wretchedly bad sanitary state. She got a tea-spoonful of spirits of turpentine in the morning, and in the evening a table-spoonful of castor oil, (by which the bowels were freely acted on,) a few days before the 22nd of March, on the morning of which the specimen of tænia, which I now show you, was expelled.

The only diagnostic symptom of tapeworm, is the appearance of it, or its segments, in the evacuations; and as the segments are shed every three or four months, by keeping a constant look out we may come to an unerring decision. I have only further to say, that unless the head be expelled, we cannot be sure that the animal will not be reproduced.

Labour, with Unusual Complication.

Dr. MADDEN, Portglenone, forwarded the following communication, which was read by Dr. Cuming:—

On the 31st December, 1858, I was summoned to attend Mrs. S. in her third confinement. On reaching the house, the noise made by the patient led me to believe that the child was on the point of being born. On examination, however, I found it otherwise. The os uteri was dilated to about the size of a shilling, and placed right over the symphysis pubis. A large tumour, in the form of a crescent, extending from side to side, occupied the posterior part of the pelvis. The tumour was so large and firm as completely to prevent the descent of the child's head into the pelvis. At first I thought it might be the rectum filled with fæces, and compressed into this peculiar shape. On,

however, emptying the rectum and bladder, I found it consisted of a misplaced or a partially retroverted state of the uterus. It was evidently formed by a fold of the uterus that had descended into the pelvis. The pains continued very severe and frequent for four hours after my arrival, without effecting the least change in the state of matters.

During this time, I made two unsuccessful attempts at reduction. Fearing that the uterus might suffer injury from the long continued pressure betwixt the child's head and the sacrum of the mother, I had her placed on her back, with her head low, and the pelvis raised. I then introduced my hand, placed my fingers along the tumour, and, having used considerable force during the absence of the pains, ultimately succeeded in reducing the part to its proper position. The os uteri was then easily brought to the centre of the pelvis, dilatation took place rapidly, and the child was expelled in about twenty minutes after the parts were righted. Mother and child did well. It might be supposed that this woman had a very large pelvis, from a fold of the uterus having thus descended before the child's head, but so far from this being the case, the forceps were used in her two previous confinements.

Council Special Meeting 16th April 1859.

Present, the President, Drs. Patterson, Dill, Murney, Cuming, Halliday, Moore, Wales.

Arrangements made for the issuing of ballot papers.

Council Ordinary Meeting April 20th 1859.

Present, the President, Drs. Dill, Heeney, Wales.

Moved by Dr. Murney seconded by Dr. Dill and resolved That a special meeting for the purpose of examining ballot papers and preparing weekly circular be held on Thursday 28th April at 2 o'clock and that the ordinary Council meeting on Wednesday be not held.

Circular prepared.

TWENTY-FIFTH MEETING.

23rd April, 1859.

{Rough minute book: President in the chair, Drs. Ferguson, McClelland, Wales, Bryce, Heeney, S. Reid, Dunlop, Halliday, Drennan, Murney, Moore, Johnston, Wales [sic], Harkin, Stewart, Reade, M'Minn, Ross.}

Rheumatic Arthritis.

Dr. DRENNAN presented a man, aged 60, a carpenter by trade, who had been admitted into hospital with chronic bronchitis, and complaining, likewise, of pain in left arm and shoulder. This pain, he asserts, was first felt between two and three months ago, and has persisted since in variable degree. The shoulder joint

has undergone a marked change in form, which the patient himself, however, had not noticed. The acromion is higher than on the opposite side; the roundness of the shoulder is lost; and the axis of the limb altered. The head of the humerus is above and within its normal situation, and crepitus is perceived on moving it. The elbow cannot be brought into apposition with the side, nor the arm raised beyond a horizontal line, whilst its under movements are performed with facility. The other joints seem unaffected.

Dr. DRENNAN considered this an example of Rheumatic Arthritis, as described by Mr. Adams. Its progress to luxation seems to have been remarkably rapid. The man is of intemperate habits, and, notwithstanding his denial, a fall may perhaps have led to, or aggravated, the arthritic affection.

{Rough minute book: Dr. Murney said that there was bony deposit the whole shoulder being mobile.

Dr. Moore thought there was distraction and ossific deposit.

Dr. Halliday introduced a woman who had been the subject of exfoliation of the parietal bone.

The President exhibited a *lusus naturæ* sent by Dr. Charles of Cookstown.}

Cases of Uterine Phlebitis.

Dr. BRYCE read the following paper:—

I have proposed to bring under your notice six cases, which I will designate as uterine phlebitis, as they resemble that complaint more than any other occurring in the puerperal state. In order to be as brief as possible, I will detail the symptoms occurring in the first case, and then notice any peculiarities occurring in the other five.

Mrs. O. was confined on the 27th April, 1858, I did not see her again until the 30th; found the abdomen greatly enlarged, especially over the epigastric region; the uterus was tender to the touch and greatly enlarged, as large as the gravid uterus at the sixth month. In none of the other cases was the uterus so large as in this, owing, I suppose, to the length of time that elapsed before there was any treatment. The pulse ranged from 120 to 140, the attacks were not preceded by shivering, nor were there any febrile symptoms of any consequence. There was no peritonæal tenderness.

There was little or no pain, except on pressure: in fact, no urgent symptom to attract the attention of the attendants. This patient's labours were always difficult, requiring the use of the forceps. She sank rapidly, and died on the 1st of May, the fifth day after her confinement.

The second case was also delivered by the forceps, in this and the previous labour, although on twelve previous labours she received no assistance. She made a tedious recovery.

The third case differed from the first two in having

considerable head affection. She became quite delirious (so that she could with difficulty be restrained), accompanied with hysterical screaming. This might be owing to her having drunk whiskey to intoxication shortly after her delivery, and to being greatly disturbed the night after her confinement. She died on the sixth day.

Case fourth. This patient was considered out of danger on the fifth day, but was seized with excessive hæmorrhage about 2 p.m. on that day, and gradually sank, and died on the sixth day. In this case the labour was tedious, in consequence of an unnaturally enlarged and pendulous abdomen.

In the fifth case the labour was easy. On the next day after her confinement, and a few hours after the other symptoms set in, she became incoherent, or rather she could not find the proper word to express what she meant, and her articulation was indistinct. These symptoms went completely off, but returned again two or three times in the twenty-four hours. When the general swelling had been somewhat reduced, the transverse colon could be traced through its whole length, distended to the utmost degree, and tympanitic. There was no tympanitis over any other part of the abdomen, in this, or in any of the other cases; but when pressed on, it gave the same feeling as a bladder half filled with fluid, although, of course, distended with air. On the fourth day all symptoms of danger had disappeared, and the pulse had fallen to 90, but on the evening of the same day she became suddenly worse, and died on the sixth day.

Case sixth presented no peculiarity, only that the symptoms presented themselves sooner than in the other cases, coming on in six hours after delivery, whereas, the others were from ten to fifteen. The labour in this case was difficult, and the child dead.

I gave 10 grains of calomel with 2 of opium, followed in three hours by $\frac{3}{4}$ of an ounce of oil of turpentine and some castor oil. This reduced the swelling considerably. This was followed by calomel and opium, in small and frequently-repeated doses, until the mouth was affected. At the same time leeches were applied over the uterus, followed by a blister; the leeching was repeated eight or ten times, and the blister applied twice. This patient recovered after twenty days' treatment.

Cases of Diphtheria.

Dr. HALLIDAY read the following—My attention has, within the last few weeks, been directed to a peculiar form of disease, differing widely in its character from anything which I have heretofore witnessed; and, as no reasonable doubt can now be entertained, that the disease which has been termed "Diphtheria," is epidemic in parts of England, and partly so in this country, I thought it might be well to give to the Society a short account of two or three cases which have fallen

under my own observation.

The first was that of a boy, aged 4 years and 4 months, of delicate constitution, but in ordinary good health, who took ill on Saturday evening, 29th January, with symptoms of influenza, of which other members in the family had been complaining. His mother gave him a purgative powder, and he appeared to be quite better on the following Sunday, and part of Monday; on this night he became restless and feverish, asking frequently for drink. Up to this time, and even on to Friday, there was no evidence of throat affection; but on this day, his mother enquiring as to the seat of illness, he pointed to his head and throat, and she remarked a stiffness in his neck when turning.

He rested very badly on Friday night, and on Saturday morning, at eleven o'clock, she remarked, for the first time, that his breathing was somewhat croupy. He was able to swallow without difficulty. Shortly after this, I visited him for the first time, and, on examination, found the tonsils slightly inflamed, and a whitish yellow slough occupying the back part of fauces; pulse, 120; tongue slightly furred; skin hot; countenance thoughtfully anxious. The solid nitrate was freely applied, which appeared to afford relief. The bowels having been freely acted on, I prescribed a diaph. mixt. Visited again same evening. The breathing, which had been much relieved, was again becoming difficult. Ordered a turpentine stupe and a mixt. containing chlorate of potass. On Sunday morning, the symptoms were much as they had been on Saturday at same hour; he had passed a restless night, and had difficult breathing, with occasional spasm. The caustic in solution was again applied, with slight relief. Ordered a blister round the throat, and a calomel purgative, but without any marked benefit; the symptoms went on increasing. Saw him again at 3 p.m., and at 10 o'clock, and, as there was no improvement, decided, on consultation with Surgeon Browne, on performing laryngotomy, as affording a last chance, but shortly after the operation, he sank calmly, as if from exhaustion, dying on the eighth day.

I have been particular in describing this case, as the two following were very much like to it.

The second, was that of a little girl, aged 3 years and 8 months, who enjoyed good health up to 18th March, when she was observed to be feverish and restless, with slight cough. Saw her in my own house, on Monday, the 21st. There was then slight redness of throat, and also a swelling in submaxillary region, on both sides.

At first, I thought it might be scarlatina. I prescribed a couple of aperient powders, and she left. On Tuesday night, dyspnoea set in, and, on Wednesday, I visited her at her own home. She was still feverish, with rapid pulse, and, on examination, I found a yellowish slough situated on the left tonsil. In this case, I

prescribed calomel in small doses, applied caustic, and blistered. I also gave the chlorate of potass, and supported the strength with chicken broth. On Sunday, the 26th, she was much better, the croupy breathing had left completely, but on Monday morning, she was much worse. She had coughed severely during the night, and the other tonsil was now affected, having passed an exceedingly, restless night. She died on Tuesday, the 29th, tenth day of illness. Surgeon Browne saw this case also with me, and we agreed that an operation would not be likely to afford any relief.

My third case was that of a female child, aged 1 year and 9 months, who took ill on Sunday, the 10th April, with slight cough and feverishness. On Monday, the 11th, she was much worse, and her mother observed a slight swelling on left side of neck, under the jaw; all this time she made no complaint of throat, and swallowed well, but on this night, her mother became alarmed at what she called a "choking in her sleep."

I saw her on Tuesday, the 12th, at Dispensary, the throat was apparently ulcerated, and the tonsils slightly inflamed. I gave nothing in this case save the tinct. ferri mur. 5 drops every fourth hour, and kept hot stupes constantly round the throat. On Thursday she was somewhat better, but became worse on this night, and died on Friday morning, at 9 o'clock, apparently of croup, on the sixth day. The mode of death in these cases, and the course of the disease, correspond with the description given by Bretonneau, and is similar to what has taken place in England, viz., that it is first pharyngeal, extending afterwards to the air passages, and very few are stated to have been saved by tracheotomy. In none of these cases could I obtain a post mortem examination, which I regret. Dr. Corriگان has given a description of a case in the *Dublin Hospital Gazette*, for February, in which the post mortem appearance was described, and dwells upon the peculiar form of the swelling in neck, as likely, perhaps, to form a distinguishing mark. I may add, that the throat, in my cases, presented more the appearance of ulceration, coupled with slough, than that of being covered with the pasty exudation described by writers on this disease; and my little patients had all been previously well nourished, and living in healthy localities.

{Rough minute book: Dr. Harkin had seen a child with cough, sore throat, no croup, great salivation, small ulcers on the lips and tip of tongue. Died of croup refractory all remedies. His aunts went to see it, a child in each house took ill with croup, both ulcers on tongue and lips.

Dr. Heeney saw 4 or 5 cases of ill-defined nature in all which disease commenced as sore throat. Tonsils swollen in some but whitish exudate in back of throat sometimes extending to tonsils. All recovered. Marked with caustics in the first instance then tonics

and nutritious diet. Solid caustics disagreed producing ulceration. 15 grains to ounce, ulceration not present.

Dr. Ferguson asked had any affection of the nasal fossæ been present. In his case two had died and of croup. Would recommend hot moisture.

Dr. Reade said that he had seen 3 members of a family who all had grume into the nasal fossæ and not into the trachea.}

Council Special Meeting Thursday April 28th 1859.

In accordance with circular calling a special meeting of Council to examine ballot papers and prepare circular, the Council met this day at 2 o'clock.

Present, the President, Drs. Dill, Halliday, Heeney, Cuming & Wales.

It was proposed by Dr. Dill seconded by Dr. Heeney and resolved that the examination of all the voting lists then in the possession of the Council be proceeded with.

The following is the result of the counting.

For President. 1st Professor Reid had 22 votes, Dr. Thomas Reade 7 votes, Dr. Murney 6, Professor Ferguson 3, Dr. Pirrie 1 vote, Dr. McMechan 1.

For Town Vice-President. 1st Dr. Murney had 10 votes, which with 6 for President make 16, 2nd Dr. Thomas Reade 8 votes which with 7 makes 15, 3rd Professor Gordon 11, Dr. Drennan 9, Dr. Dill had 9 votes, Patterson 8, Heeney 7, Bryce 7, Pirrie 6+1 as President 7, Professor Reid 6, Professor Ferguson 4+3 as President 7, Dr. C. Purdon 4 votes, Wales 4, Ross 3, Mr. Johnston 3, Dr. W. MacCormac 3, M'Gee 2, Andrews 1 vote, Stewart 1, Mulholland 1, Cuming 1, Mawhinney 1, Aiken 1.

For Country Vice-Presidents. 1st Dr. Babington Derry 12, 2nd Ferris Larne 6, McMechan Whitehouse 4+1 as President 5, [Maionely?] Downpatrick 4, Mr. Madden Portglenone 4, M'Laughlin Lurgan 4 votes, M'Caldrin 4, Graves Cookstown 4, Dunlop Holywood 4, Bruncker 3, Patten Tandragee 3, Clugston Ballyclare 2, Mahood Enniskillen 2, Gassen Coleraine 2, Jamison Newtownards 2, Dickson Ballynahinch 2, Smith Dublin 1 vote, Diamond Rasharkin 1, Forsyth Culmore 1, Stewart Asylum 1, Knox 1, Nixon Antrim 1, Kelso Lisburn 1, Taggart 1, Frame Comber 1, Scott 1.

For members of Council. 1st Dr. Drennan had 12 votes +9 for V.P. 21 votes, 2nd Patterson 10+8 18, 3rd Dill 9+9 18, 4th Dr. Pirrie had 11 votes +6 as V.P. 17 votes, 5th Mr. Johnston 14+3 17, 6th Dr. Bryce 7+7 14, 6th Heeney 7+7 14, Ross 9+3 12, Professor Gordon 8, Dr. Murney 8, Professor Ferguson 4+4 8, Dr. C. Purdon 4+4 8, Mr. M'Cleery 7, Harkin 7, Browne 7, Dr. M'Gee 4+2 6, Wales 2+4 6, Corry 6, McCormack 3+2 5, Moore 5, Stewart 3+2 5, Dunlop 1+4 5, Cuming 4+1 5, McCaldin 1+4 5, Mulholland 3+1 4, Halliday 4, McMinn 3, Professor Hodges 3, Dr. Wheeler 3, Murray 3, Professor Andrews 2+1 per V.P. 3, Dr. Carson 1+2 3, Pro-

fessor Reid 2, Carlisle 2, Dr. Ferris 2, Stronge 2, Aiken 1+1 2, Mr. Smyth 1 vote, Rea 1, Lamont 1, Warwick 1.

The circular being prepared the proceedings terminated.

TWENTY-SIXTH MEETING.

30th April, 1859.

{Rough minute book: President, Drs. Patterson, Wales, Heeney, Murney, Gordon, Moore, Halliday, Stewart, Arnold, Seaton Reid, Johnston, Dill, Ross, Warwick, M'Minn, Mulholland, M. M'Gee, W. M'Gee, Bryce.

Dr. Murney reported that he had made a partial examination of the *lusus naturæ* of Dr. Charles. A cast ordered to be taken and Dr. Murney to furnish a report for the transactions.

Dr. Murney exhibited a small uterus with an enlarged ovary consisting of granular fat with lesions in the centre.}

Fracture of Clavicle Between the Coraco-clavicular Ligaments.

Dr. GORDON read the following paper:—

This specimen of an old and ununited fracture of the clavicle between the coraco-clavicular ligaments, was taken from the body of a man who died during the past week of traumatic delirium, supervening on an extensive lacerated wound of the scalp. The deformity, from projection backwards of the trapezius muscle by the outer end of the inner or sternal fragment, was well marked. The fracture is oblique from behind forwards, being, posteriorly, 10 lines distant from the acromio-clavicular articulation; but it is, anteriorly, 16 lines. There is no osseous union, and the ligamentous bands which, unite the fragments are thick and strong. The articular surface of the outer fragment is applied against the anterior border of the inner fragment; the end of the latter is free, and projects considerably beyond the former, and instead of looking directly upwards, it has undergone a slight degree of rotation, so that its upper surface looks upwards and forwards. The tubercle on its under surface, which lies above the angle of the coracoid process, is surmounted by an osseous process, about half-an-inch in length, to the extreme end of which the conoid ligament is attached. Between this process and the insertion of the trapezoid ligament, there is a space of half-an-inch unoccupied by any of the attachments of the conoid or trapezoid ligaments, but the seat of a considerable amount of ossific deposition, nature having formed a glenoid cavity, with prominent margins on the anterior border of inner fragment, to receive the rounded head of the inner extremity of the outer or acromial fragment. This example, the third which I have met within less than six months, fully corroborates the remarks which I

previously made during the present session regarding this form of fracture; and, I am now more surprised, that the true nature of an accident, seemingly so common, should have been hitherto completely overlooked by surgeons.

Osteo-cancer of Shoulder.

Dr. MOORE exhibited a cast of a gigantic example of osteo-cancer of shoulder. The cast had been taken after the death of the patient, and coloured by Dr. Moore, so as to represent accurately the appearance presented during life. The patient was about 20 years of age. The new feature of the case was the enormous size to which the tumour attained, and its extremely rapid progress, the disease having appeared about four months before the death of the patient.

When seen by Dr. Moore, the disease had invaded the textures connected with the shoulder joint to such an extent as to preclude all operative interference. He remained at home under the care of his ordinary medical attendant. The disease having all the appearances of a malignant growth, advanced rapidly, engaging the entire shoulder, neck, superior part of breast and arm, as far as junction of lower and middle thirds of humerus, and attained the magnitude of an ordinary small-sized bees'-cap. It ulcerated at three points, discharging sanious fluid, with occasionally clots of blood. By this discharge the tumour was reduced in size, and frequent hæmorrhages occurring, the patient succumbed. On cutting down on the shoulder joint, the whole osseous textures therein engaged had almost disappeared, leaving only a mere friable shell.

{Rough minute book: Dr. Murney made some observations as to the rapidity of the growth.

Dr. M'Gee asked had the tortuous state of the veins brought Dr. M. to the conclusion that malignant disease existed.

Dr. Gordon said that the enlargement of the veins was characteristic pattern with pain and tumour in this situation.}

Dr. MOORE also exhibited a cast of foot after removal, in the case of elephantiasis which he had brought before the Society at a previous meeting.

Cases of Tracheotomy.

Dr. MURNEY read the following—

I propose to bring under your notice, the history and results of some cases which required tracheotomy. The reports are taken from my hospital book, but I have curtailed them as far as adherence to the peculiarities and features of interest would warrant.

On the 6th February, 1854, a girl, 2 years old, was admitted into the General Hospital. Some time previously, when thirsty, she attempted to take a drink from the spout of a kettle which contained boiling

water. A quantity of steam, was, of course, inhaled, scalding the mouth, upper portions of pharynx and larynx. She was brought to a practitioner in the neighbourhood, who smeared the parts with oil, and directed her to be taken to hospital if the symptoms became more urgent. Some time, therefore, elapsed, before her admission into this institution. When seen by the resident pupil, her respiration was hurried and laboured; expression of countenance anxious; the uvula large and tense, and the fauces congested. A concentrated solution of nitrate of silver was applied with decided relief, and a mustard synapism placed over the anterior region of the neck. For an hour the respiration became easier, and the symptoms abated. At a quarter before nine o'clock, I saw her, when I was informed the symptoms were becoming more alarming. Strong ammonia was applied externally, so as to vesicate, and the pharynx "swabbed" with solution of nitrate of silver. At ten o'clock, the temporary advantage resulting from the last treatment having subsided, no prospect remained for the preservation of life, save by the performance of tracheotomy, which was done in the usual mode, eight hours after the inhalation of steam.

The trachea was opened close above the thyroid body, and a part of a full-sized flexible catheter introduced and tied in the wound; not more than half an ounce of blood was lost during the operation. Immediately, after some four or five deep inspirations, the child fell into a placid and refreshing sleep. I need not follow the daily reports, but may mention, until the 9th, she progressed favourably; she had now, however, accelerated pulse, although stated to have slept well. On the 14th, she had general bronchitis, which could not be in any way controlled. She died on the 26th February, twenty days after the performance of the operation. The treatment consisted in placing the little patient's bed close to a fire, so that the atmosphere around her was but slightly influenced by external cold; the administration of small doses of calomel, combined with compound hippo powder, in the early stages; and, during the progress of the bronchitis, carbonate of ammonia, in decoction of senega. Stimulation was also used to the surface of the chest, but without any benefit.

The second case occurred on the 2nd January, 1858. It was that of a little girl, aged two years, who also inhaled steam from a kettle, had similar symptoms, and was brought to hospital 6 hours after the unfortunate occurrence. I saw her shortly after admission; external stimulation and caustic solution were here also applied, but with only temporary benefit. At 7½ p.m., viz.—7½ hours after the accident, I opened the trachea at the same part as in the last case. During the operation I tied two arterial twigs, and from the highly congested condition of the veins, there was pretty smart venous hæmorrhage, which

ceased after a few deep inspirations.

On the introduction of the gum-elastic tube into the opening, some blood escaped by its side into the trachea, which produced suffocating cough. To remove this I found it necessary to apply my lips to the wound, and suck out the blood. As in the former case the patient fell asleep immediately after the operation.

Bronchitis set in at once, and the patient died on January 7th, five days after operation. I need not particularize the treatment, as in many respects it was the same as that detailed more at length for the first case.

On the 6th November, 1858, at noon, a fine little boy, aged three years, was admitted into hospital labouring under all the symptoms of œdema of the glottis, caused, as in the other cases, by the inhalation of steam from the pipe of a kettle; the occurrence took place at 9 a.m. Again was I induced to try the application of solution of nitrate of silver; and, as the surface was cold and somewhat dusky in hue, partly from incomplete clothing on a cold day, and partly from obstructed respiration, I placed him in a bath at 110 deg. F. for eight or nine minutes; relief of a decided but only temporary character followed. Again the solution of caustic was used, but with the usual result. At half past one, p.m., namely, four hours and a half after the inhalation of steam, on consultation, tracheotomy was deemed necessary and immediately performed. During its progress nothing untoward occurred; two small vessels spouted, but were immediately secured. He continued to improve till the 10th, when he suffered from bronchitis. Till the 13th this gradually became worse,—on which day and the 14th the severity of the symptoms caused me to fear he would not survive. Steadily, however, the cough diminished, and on the 20th he was convalescent. On the night of Monday, the 22nd November, we had, I believe, the first intense frost experienced this winter. Unfortunately, on the evening of that day the fire in the ward (which was close by the patient's bed, and about which I had been most particular and precise in my directions,) was neglected, and died out about six o'clock. The temperature of the room was gradually sinking, and I suppose about nine was little above that of the lobby or stair. Shortly after the child became restless and fretful, had teasing, irritating, then difficult and croupy cough. I saw him shortly after midnight, and certainly feared all our attention and care were about to prove unavailing; but in a little time he began to exhibit the good effects of a fine fire warming the cold air, and I considered he was also greatly benefitted by a turpentine stupe, which I directed to be applied all round his chest. In the morning he was greatly improved, and in a couple of days he was again convalescent. Considerable caution was exercised in confining the patient, when almost recovered, at first

to his bed, after a time in allowing him to play about the ward, and later on, on mild days in permitting him to expose himself to the colder currents of the lobbies and stairs. He was discharged quite well on the 3rd December. The wound in the trachea had completely cicatrized on the 22nd November, so that, had the difficulty of respiration become greater, another opening of the windpipe would have been necessary, which would have been more troublesome in the performance, and assuredly would have been undertaken with a much more unfavourable prognosis than the original operation.

On the 12th November, 1858, a man, aged 31 years, unmarried, was admitted into one of the medical wards, labouring under an attack of laryngitis, which commenced six weeks previously. He had placed himself successively under the care of two practitioners, from whose treatment he derived some temporary benefit; but, the recurrence of his symptoms, in a more severe form, induced his last attendant to recommend him to hospital. When first visited, he had pain on pressure over the region of the larynx, especially between the *alæ* of the thyroid cartilage; hurried and difficult respiration, each inspiratory effort being accompanied by a crowing sound, which could be heard at some distance from the ward he occupied, even when the door was closed. Four years ago, he had a sore on the penis, after connection, which in a little time healed up. Never had any eruption or other constitutional result of syphilis. The sore was never shown to a medical man, but was treated under the advice of some acquaintance, so that the existence of venereal taint, although probable, could not be ascertained with certainty. On Monday, the 15th, the pain about the larynx, and difficulty of respiration, had increased so much, I recommended tracheotomy, but a number of his friends induced him to leave the hospital. On the 16th, about eleven p.m., I was sent for by my friend, Dr. Heeney, to perform the operation. I found the man in a miserable apartment, surrounded by a number of his friends—several of the male portion more or less intoxicated. He was much worse than when I had last seen him. His lips were blue, the surface dark, and it was apparent, the quantity of air passing to the lungs was now very small, and momentarily diminishing. My friend and I agreed we could not venture to remove him to hospital before operation, nay, I even feared to leave the house to get a tracheal tube, as I had not one with me, so imminent was the state of asphyxia. Before proceeding farther, I would explain the reasons for choosing another and a more difficult operation than that which was performed in the cases of œdema of the glottis. The connection between syphilis and the present affection being very obscure, it was impossible to form any estimate of the extent of the disease in the larynx, and therefore I would not perform laryngotomy for

the same reasons I avoided that part of the trachea above the thyroid body. I therefore determined to open the windpipe at the more difficult, *but, apart from the operation*, the safer locality, immediately below the azygos lobe of the gland. For this purpose, assisted by Dr. Heeney, I made my incision in the usual region, when having, of course, cut some turgid veins, from which a good deal of blood poured, I naturally waited a few seconds to sponge the surface, when I observed respiration had ceased. Nothing then remained but to open the trachea at all hazards, which was immediately done.

In previous operations, the plunge of the knife had been invariably followed by a gush of air into the tube. Now no such pleasant sound was heard. The man was virtually dead, and remained so for at least thirty or thirty-five seconds, during which time I thrice applied my lips to the wound, and sucked from the trachea large mouthfuls of blood, when at first, slowly and imperfectly, then more deeply, the respiration returned; subsequently I introduced a tube and had him removed to hospital, where, having passed through a smart attack of bronchitis, he recovered. There has been complete occlusion of the larynx for more than five months; and I do not anticipate he will ever be able to permit the closure of the artificial opening.

From a consideration of the anatomy of the parts occupying the median line of the neck, I consider there are two situations at which the trachea may be opened—viz., one above, the other below the median lobe of the thyroid body. The former is much the more simple operation, and, I believe, is applicable to the great majority of cases; in fact, at this moment, I do not recollect any instance in which, as I would style it, the low operation should be performed, except a case such as that just detailed, or where a foreign body has passed through the larynx into the trachea, and is, perhaps, situated at the lower part of that tube. The isthmus of the thyroid rests anterior to the third ring of the trachea, consequently, the upper two rings may be reached with some facility, and, when we consider, usually there are no vessels or parts of importance very near to this region, that its depth from the surface is not very considerable in the child, and there are not usually so many turgid veins as exist where the inferior operation is to be executed, there cannot be a doubt as to which locality should be chosen, unless when special contra-indication existed. A little point in the progress of the operation, I think, is not sufficiently insisted upon by surgical writers. It is—in the dissection of this part of the neck we find four layers of fascia, three of which will be cut through in ordinary fashion, and do not require any special notice. The fourth layer is that which lies between the sterno-thyroid muscle and the trachea. It is of considerable thickness and strength. Now,

more than once I have observed, unless care be taken, this membrane was cut, and the trachea not opened until the knife was used a second time. Its position should therefore be borne in recollection, and when cut, I would suggest, the opening should be free, as from the tossing of the patient the orifices in the membrane and the windpipe may not correspond, resulting in impeded respiration to the patient, and some trouble to the operator in the introduction of the tube.

I cannot find any statistics to place before you the results of a number of operations on the windpipe, but I believe I am warranted in saying, at the age of five, seven, or ten, the deaths are not much more numerous than occur with adults, but that during the first two or three years the mortality is very high, and the question naturally arises, Can this be attributed to any source susceptible of removal or mitigation? Now, it is well known, one of the most frequent causes of death after operation for strangulated hernia is having permitted too long a period to elapse before resorting to the knife, and I am fully persuaded the performance of tracheotomy at an earlier period than has hitherto been customary would give the patient a better chance of life; for it seems that by delaying until a condition of venous congestion is produced, and allowed to exist with increasing intensity for a time, we have a lowered tone of vitality induced in the lungs, and perhaps in other organs, but especially the lungs, about to be subjected to various causes which would set up inflammation—certainly a state the most unfavourable. As a probable cause of the greater mortality among young subjects, I would suggest that, as the capillary circulation is so remarkably active, the condition of lowered vitality will be more rapidly induced than in those of more advanced years, and, of course, there is, in addition, that tendency to succumb to any serious disease so invariably exhibited in children.

{Rough minute book: Dr. M'Gee said that the change of position in placing the patient in the horizontal position as orthopnoea had existed generally before operation has been recorded.

Dr. Murney agreed with Dr. M'Gee with regard to the cause of the asphyxia being the position in which the head was placed.

Dr. Moore said that his father had operated in a case in which the patient was given over after the operation.

Dr. Gordon said that there should be a bit of wire keeping the wound open and that no tube should be used. He said that when infiltration has taken place nitrate of silver should not be applied. It was useful in chronic cases but not in cases when inflammation has not checked its acme.

M'Minn and Bryce auditors.}

Examination of Specimen of "Lusus Naturæ"

Forwarded to the Pathological Society
Some Time Since.

The manubrium of the sternum is natural in all respects. The mucro is developed in the usual fashion by centres of ossification placed laterally; the right portion is larger and more fully ossified than the left; the cartilages of the ribs are connected in the normal manner to the sides of the sternum. A wide interval exists between the lateral parts of the body of this bone through which the heart is protruded, and rests in front of the thorax perfectly destitute of covering. Behind it, and separating this organ from the lungs, &c., &c., is a serous membrane, which, in a more developed condition, I consider, would have formed the serous layer of the pericardium. The heart is natural in shape except at the apex, from which a conical-shaped process, which might be styled an auricular process, passes towards the left side for about one-half inch in length, and is connected by a muscular bundle to the anterior part of the cartilage of the sixth rib. The only peculiarities observable in the dissection of the heart are, the walls of the right ventricle are very much thicker than those of the left, and from the latter cavity a *cul de sac* runs for about three lines in the interior of the “conical-shaped process,” already referred to.

Council Ordinary Meeting 4th May 1859.
Present, the President, Drs. Bryce and Wales.

The circular was prepared and the following report approved.

“At the close of the sixth session, the Council have again to report on the position and progress of the Society.

We have on our list fifty country members, three of whom are honorary, and forty-four town members, in all ninety-four, showing in comparison with last year, a decrease of four in the former and an increase in two in the latter. In connection with the notice of our strength, it may be well to attract attention to a falling off in the number of country members in the last two years, The decline amounts to no less than one third of our former number—a fact which merits attention with a view to the consideration of issues calculated to promote and sustain the interest and co-operation of our country brethren.

It is gratifying to have to record no local deflexion.

The Society has had twenty-seven meetings during the bygone session, the average attendance of members being above twenty. The students have not so generally availed themselves of the privileges given them of attending our proceedings as might have been expected, their average attendance being only eleven.

We have to record the enrollment of ten new members since our last report.

Our museum has been further enriched by the addi-

tion of sixteen casts, three of which are plaster, and thirteen coloured wax. The latter deserve special notice and commendations as faithful and beautiful facsimiles of the original morbid specimens here exhibited. With the view to make these valued works of art as serviceable to members as possible the Council would suggest to their successors their management in the approaching recess, and the publication of a comprehensive catalogue.

The past session has been unusually rich in material. The morbid specimens with few exceptions have been of the highest logical interest. The papers and cases brought forward have been very numerous, and for the most part far removed from the common order. Many of them teem with suggestive hints of great practical value. Most of them serve as illustrations of principles or opinions in surgery, pathology and therapeutics while some, the offspring of original observation, who have gone out of the beaten track in search of hidden truths have actually made known and established previously unsuspected facts. The discussion on the various subjects brought under notice have [been] exceedingly important. While they have evinced an utter freedom from personality, they have fearlessly and firmly declared individual conviction, thereby correcting error, promoting progress, and improving facts.

That our proceedings have not declined in value and importance, that on the contrary they have become more instructive and attractive, may be fairly assumed by the fact that during the present session we have had a higher average attendance with our total number at 94, than when we enrolled 123 members.

In devising means for the recovery and extension of our country connexion, we have to refer to a powerful agency already in operation, namely the weekly transactions. At an early period of this session, the Council with the view of development of our resources, to stimulate the zeal and [?] of our members, and to enlist greater general interest and support, determined on printing a weekly record of the Society's proceedings. The increased expense rendered this measure somewhat experimental in character. It has however been already largely supported having received above 50 subscribers and we have reason to believe that notwithstanding the absence of any report of the discussions, it has given considerable satisfaction, and has in some degree fulfilled the expectations of its promoters. The Council however are fully sensible of the defects of the present weekly report, and they would recommend to the consideration of the Society the printing the discussions and remarks in detail next session. To accomplish this a special reporter would be required, but the Council hazarding in some degree the value and extent of our resources, believe that the increased expense would

Belfast Clinical and Pathological Society
Sixth Session: 1858–1859
President Samuel Browne

be ultimately met by additions to our ranks and to the list of subscribers to the Transactions; and [?] these compensated by the influence which a full and carefully arranged record of our proceedings must exercise in promoting the advancement of our science, the interests and permanency of our Society, and our own individual improvement.

In conclusion while we have given prominence to our shortcomings with the view of amendment, we cannot but congratulate the Society on its unmistakable progress. While it has stirred up in the minds of our local and surrounding brethren an earnest, increased, and increasing thirst for the acquirement and extension of medical knowledge, it has afforded ample room and opportunities for its gratification.

The past session has been in every sense pleasing, rendered so by the able, zealous guidance of our esteemed President, and by the general good feeling and cordial sympathy in purpose which has uniformly animated all the members."

ANNUAL MEETING.
7th May, 1859.

{Rough minute book: The President in the chair, Drs. Patterson, Dill, Halliday, M'Minn, Wales, Ross, Seaton Reid, Mulholland, M'Cleery, Dunlop, Ferguson, Murney, Bryce, Stewart, Murray, Mr. Whitaker, Dr. W. Aickin, Cuming.

Dr. Wales read report of Council.

Moved by Dr. Wales seconded by Dr. Ferguson that the report be adopted.

Dr. Bryce read report of auditors and moved adoption. Dr. Patterson seconded.

Dr. Murney gave notice of motion that after 1st November the subscription be 12/6 and 7/6 and that the transactions be furnished.

Dr. Ferguson gave notice of motion that he would bring before the Society the question of whether the transactions be continued in this present form and what form.}

THE Council and Auditors' Reports having been read, the Office-Bearers for the ensuing Session were announced as follow:—

PRESIDENT.—Dr. J. Seaton Reid.

VICE-PRESIDENTS.—Dr. Murney, Dr. Thomas Reade, Dr. Gordon, Dr. Babington, and Mr. Ferris.

MEMBERS OF COUNCIL.—Dr. Drennan, Dr. Dill, Dr. Patterson, Dr. Pirrie, Mr. Johnston, and Dr. Heaney.

{Rough minute book: Dr. Dill gave notice that the Council's attention be given as soon as possible to the financial position of the Society and call a special meeting of the Society and that in future an additional

County Vice-President [be appointed].}

After which the retiring President delivered his closing address, the business being brought to a close by a vote of thanks to the Ex-President, Honorary Secretaries, and Treasurer, separately, and by the installation of the President-Elect.

Paper.¹ It now becomes my duty, gentlemen, to bring the sixth session of the Belfast Pathological Society to a close. Before, however, I resign the chair in which your kindness placed me for the bygone year, I crave your indulgence while I make a few observations which, I trust, you will consider appropriate to the occasion. In the first place, then, I may say that I have just grounds for offering you my congratulations on the success of the session that has terminated. On a review of the papers brought forward, and the discussions to which they gave rise, I feel I may affirm that, for accuracy of research, truthfulness of detail, and practical and scientific deduction, they bear satisfactory comparison with those introduced before any pathological society of the Kingdom, and I can, moreover, most unaffectedly state that I have received much valuable instruction and information on several subjects, besides having had my attention directed to points of practise that I had not hitherto sufficiently weighed and investigated. In these respects, I am sure, I do not stand alone. Nay, more, I can, without the smallest disparagement of any, believe that every one of us has been materially benefited by the free interchange of sentiment which has taken place, and that the most experienced, as well as the youngest member, has gathered mental riches, as, in friendly discussion, we have expressed our own views or criticised the opinions of others. It is, gentlemen, in such interchange of thought, sometimes agreeing, and occasionally coming into—not hostile—collision, that the advantages of a society like this mainly consist, and, properly directed, duly estimated, these advantages are unquestionably great. If carefully cultivated, our society opens up a large and productive field into which each of us may cast some good seed, and from which all must reap fruitful information. The power of carrying out the culture is within ourselves; it requires but our united will, energy, and perseverance; with these, the result is beyond a doubt, the reward rich and absolutely certain. Our society, gentlemen, is but in its infancy, and, therefore admits of many of those improvements which maturer years will naturally bestow.

There is one requisite improvement to which, I trust, I may be permitted to refer, and that is with regard to the discussions elicited by the papers read here, but especially to their being published in the weekly report of our transactions. During the three last sessions, many valuable papers have been produced, important in themselves, and highly creditable to their

¹ [Belfast Newsletter, 1859, May 12, p3.]

authors. These have regularly appeared in the abstract issued to our country members, but reports of the discussions that have taken place have either been neglected, or have not been recorded and issued; I fear, indeed, that they are entirely lost to the society. Now, you will all admit that this is a great misfortune, and renders our transactions, in many respects, very meagre, and less interesting, for it will not be denied that, in the discussion, much of the practical value of the question introduced was frequently to be found. Hence, I think that some steps should be adopted by which full reports of our discussions shall be taken; and as this work could not be efficiently performed by our secretaries—indeed, it would be unreasonable to require the duty of them—it would be necessary that a reporter should be engaged for the purpose, and then that his reports should be placed in the hands of the Council to prepare them for publication. I need not enter more into details, as it will be the duty of the Council to make the necessary arrangements, if it be deemed right to carry out the suggestions I now make; at all events, I think that some steps will be considered requisite, for every one of us must have felt the desideratum to which I have referred. This question was forced upon me early in the session, and I refer to it only now, as I did not see how we could remedy the evil sooner. It is true that the published abstract usually furnished the papers, as read, and thus laid before the members such excellent matter; but these reports fell far short of giving an idea of the many valuable and practical questions to which these papers gave rise. Now, occupying, as I did, the chair at every one of our sessional meetings, I gave strict heed to the subject, and had frequently to regret the absence of arrangements by which much important information would have been preserved to the society, and would have made our sessional volume of transactions more valuable than it can now be. It is then, to supply a defect that admittedly exists that I have ventured to make the preceding remarks, and to offer the suggestions which, in conjunction with the report of the Council, I beg again respectfully to press upon your notice.

I have referred to the professional advantages which this association confers upon its members, and in which the community at large are, more or less, participators; for whatever lends to the advancement of medical science must, of necessity, advantage mankind; but, beyond this, there is here a kindly fellowship which brings us to know, and I trust to esteem, each other; and I hold that the more frequently we are thrown together and mix on friendly terms of equality, the more we shall feel, as brethren should, interested in each other's welfare, and ready to unite for the promotion of whatever is for our general weal. The longer I live, and the greater my experience of the world, the firmer becomes my conviction that it exhibits suicidal folly when the members of our profession remain disunited,

and without a common centre of co-operation. Hence, I feel it a bounden duty to promote, by every means in my power, our medical and pathological societies; and now, from this chair, before I leave it for the last time, I would affectionately entreat my brethren to be kindly disposed one to the other, remembering that we are all engaged in the same great cause—the promotion of the health, and, consequently the happiness, of mankind. This recollection should go far to allay all our differences, and to draw us together by the gentle bonds which ought to unite in fellowship and amity those who labour together in an arduous and philanthropic undertaking. This respect towards each other, moreover, is necessary to command the respect of the world; for in no way could we more effectually mar our usefulness than by losing that esteem, and by no means are we so likely to lose it as by internal bickerings and disunion, or by individual underrating of, and keeping aloof from, one another. This, like the Medical Society, is, in some measure, for us a bond of union; but neither of these societies, in my opinion, is made to perform the professional social good of which each is capable, and, although they are centres round which our brethren of Ulster should rally, I feel they are not so esteemed, and are not sufficiently made the media of promoting the interests of our common profession. With whom the blame rests I will not venture to affirm; but I fear that we of the town are somewhat careless of what does not seem to affect ourselves immediately, and that our country brethren are rather apathetic. Yet both parties may rest assured that whatever affects the interests of the one must, more or less, bear upon the other, and that union and hearty co-operation, in all cases, would give us double strength. Holding such views, then I feel that it is my duty to urge the extension of our society so that, as far as possible, it may be made to embrace the wide extent of Ulster; and that it shall be not only, as at present, the medium of our scientific communication, but also, the focus, under certain limitations, of our professional action in all that affects the brethren. I am not aware whether this latter object was contemplated by the estimable founder of our society (Doctor Malcolm); but every one who remembers his zeal, his esprit de corps, his untiring energy, in all that concerned our interests, will readily believe that, nothing could have rejoiced him more than to see the association he had called into existence spreading its influence far and wide, and giving union and stability to our body.

This union and stability are highly desirable, as I for one believe that, till we are more united, we must fall far short of duly fulfilling our mission. It cannot be denied that our influence is not at all commensurate with the opportunities we have for promoting our common interests, and that we are not held in the esteem we should be by a community which owes so much to our profession. This want of position or respect is not any fault of the public; the blame must rest with ourselves. I

often hear and read melancholy complaints of the small value the public is inclined to put upon our services; but, while I admit the truth of the complaints, and know the readiness with which every community ignores our usefulness, I also feel that the evil originates with ourselves, and that the unbecoming jealousies and the personal strife which disgrace our body lay the foundation for nearly all the social disabilities we endure. Nearly all of us may be personally honoured and esteemed, and, within certain limits, can exercise considerable power; but, as a body, we fall very far short of commanding an influence at all commensurate with what belongs to us individually—the individual power, in fact, loses considerably in the aggregate, and this is naturally the result of disunion. And, gentlemen, until very recently, our co-members of the public service have even suffered from the very causes which operate against us in private life. Our want of influence extended to, and affected their interests, both in the army and navy; at length, however, these invaluable officers sought, and, by union, obtained, redress, and, in the struggle, they were warmly and generously sustained by the entire profession, which, however disunited and at variance regarding their own social interests, worked harmoniously to obtain for their ill-requited brethren of the two services at least an instalment of the rights which had long been denied to them, and these benefits are now likely to be largely increased in the prospect of war. We cannot but deplore the horrors of war; we cannot but earnestly hope that they may be averted from us; yet, if it becomes necessary that England shall be engaged in the defence of her honour, or of the right, we must also rejoice that our brethren, who will be called on to exercise their humane duty amid the crash of battle or in the face of the dire pestilence, will have the consolation of feeling that their services will be more valued than they have ever hitherto been, and that, in the day of honourable reward, they will not be forgotten.

Perhaps at no period have the union and stability to which I have referred been more required than in these days. After many years of barren legislation, a measure of medical reform has, at last, been passed into a law; that Act I shall not venture to criticise, because it would scarcely be fair to find fault with or praise a measure not yet fully in operation; but this much I may say, that we can only regard it as an instalment of what was urgently required, and what our interests yet demand. Still, such as it is, we must accept it, and it becomes our duty to render its protective provisions as effective as possible, and to use all the influence we possess towards the carrying out of those clauses which affect unqualified practitioners. These steps can only be taken, however, when the list of registered medical practitioners shall have been published. But, in the meantime, our union and steady watchfulness are necessary to guard against the several kinds of quackery which, under the

guise of medical science, are mere specious pretences. These should have our determined opposition; they should not find any favour at our hands. For I hold that, if we do not, on all fitting occasions, oppose and expose them, we are tacitly assisting in the deception—we are permitting the world to believe that our minds are unsettled on the question. Thus do we sanction judgment to go by default; but, above all, in a cowardly manner we permit the profession we are bound to defend to be trampled on. And why? Is it not because we are too disunited, too timid, too time-serving, and fearful of creating enemies? No one should unnecessarily provoke enmity; but, when a great principle is at stake, I hold that no man who values his privileges should shrink from maintaining them, in opposition to everyone whom he considers in the wrong, and he must never yield a principle for expediency sake, or conciliate any man by admitting an error to assume the place of truth. When I was called to this chair, at the commencement of the session. I felt myself necessitated to express my opinion on some of the medical heresies of the day. This I did, fully and fearlessly, and I do not now regret the course I then pursued, nay, I now reiterate every word I uttered against them.

Some of my brethren, I believe, considered that my attack upon certain quackeries was calculated to serve rather than damage those systems; whether they still adhere to that notion I know not, but I am satisfied that, when the gage had been thrown down, I was not only right, but was called on, from my position as president of this society, to take it up. Nay, more, I feel that, had I not done so, I would have merited your contempt, and, certainly, I must have despised myself. Just look across the Channel, and see the pusillanimous and time-serving course pursued by some members of a medical association there, and ask yourselves whether those who, under the guise of pseudo-liberalism, contended for the admission of homeoquacks to the privileges of that society did not display an utter disregard for the honour and interests of the professions? How they could have acted so I am at a loss to conceive, unless I believe that they had a decided leaning to the system, without the courage to confess their real sentiments. The majority, however, have nobly vindicated the character of the association, and have taught a lesson to homœoquacks and their sympathisers which these gentlemen will not readily forget.

The Council has suggested—and I quite agree with their views—that some means should be adopted by which country practitioners may be induced to become members. Indeed, I believe that the report of the transactions may be made so ample and interesting as to create a desire on the part of nearly every medical man in Ulster to join with us, and I hope that, before the opening of next session, the Council will have matured a plan by which every inducement will be held out to our country brethren, and that we shall have a great

increase of our enrolled members.

The remarks of the Council relative to the museum are worthy of the most attentive consideration. We have now amassed a valuable collection of pathological specimens and illustrations; but, until they shall have been properly arranged, described, and tabulated in a catalogue, they must remain nearly useless. Indeed, to the majority of our members, they are as a sealed book; hence the earliest duty of our new Council, I respectfully submit, will be the careful examination of the collection and the arrangement of it, so as to make it available; and, as I shall still, *ex-officio*, be a member of Council, I shall have great pleasure in devoting a portion of my time during the Summer to this essentially necessary undertaking. To the general body of the members I would earnestly recommend the storing up of clinical facts and observations during the recess, and the pursuit of pathological research whenever opportunity offers, so that we shall have ample stock of matter wherewith to begin the ensuing session. I throw out this hint as I know that men are too apt to disregard that which they cannot turn to immediate use, and overlook many useful and interesting matters, but of which they do not happen to stand in need, or for which they are not then in search.

And now, gentlemen, it only remains for me to thank you, in the first place, for the honour which you conferred when you called on me to preside over your deliberations. This, like every other professional distinction which you and the Medical Society have bestowed, I owe entirely to the kindness of my brethren, not to any merit of my own. That friendly esteem I hope I shall still continue to possess. In the next place, I have to tender you my very grateful acknowledgements for the unwearied interest which has attended the progress of the past session, and for the anxiety all have manifested to render the papers and discussions of practical value. The President's duty is easily performed, where the members vie with each other in courtesy, and in the maintenance of the order of discussion. Such I have felt to be my position at every one of our meetings; and I shall ever look back upon my presidency of the Belfast Clinical and Pathological Society with feelings of satisfaction and gratitude. (Applause.)

{Rough minute book: The new President was then installed, and returned thanks.

Dr. Ferguson moved that the thanks of the Society be given to the retiring President. Seconded by Dr. Cuming and carried by acclamation.

Dr. Patterson moved that the thanks be given to the Secretaries and that they be requested to continue their services. Seconded by Dr. Bryce.

Dr. Murney moved that the thanks of the Society be given to Dr. Halliday and that he be requested to continue. Mr. Browne seconded.

Dr. Bryce moved the publication of the President's

address. Dr. Ross seconded.}

Belfast Clinical and Pathological Society
Seventh Session: 1859–1860
President James Seaton Reid

BELFAST CLINICAL AND PATHOLOGICAL SOCIETY

SEVENTH SESSION

1859–1860.

OFFICE-BEARERS
FOR THE SESSION 1859–00.

PRESIDENT.
PROFESSOR J. SEATON REID, M.D.

VICE-PRESIDENTS.

RESIDENT,	NON-RESIDENT,
DR. MURNEY.	DR. BABINGTON,
DR. THOS. READE.	Londonderry.
DR. GORDON.	SURGEON FERRIS,
	Larne.

SURGEON BROWNE, R.N., *Ex-President*.

TREASURER.
DR. HALLIDAY.

HON. SECRETARIES.

DR. CUMING, DR. WALES.

COUNCIL.

DR. DRENNAN.	DR. DILL.
DR. PATTERSON.	DR. PIRRIE.
DR. HEENEY.	SURGEON JOHNSTON.

BELFAST
CLINICAL AND PATHOLOGICAL SOCIETY.

SEVENTH SESSION—1859–60.

Council Special Meeting May 19th 1859.
Present, the President, Professor Reid, Mr. Browne, Dr. Dill, Dr. Murney, Dr. Wales.

The recommendations of Ex-President and Council considered with the view of extension of the reports of the Society at a reduced expense.

The meeting adjourned until 26th May 1859.

Council Special Meeting 26th May 1859.
Present, the President, Drs. Drennan, Patterson, Dill, Johnston, Heeney & Wales.

With the view to increase the revenue of the Society so as to meet the increased expenses of publication &c. It was moved by Dr. Murney seconded by Dr. Patterson and unanimously resolved that as a recommendation of Council That the subscription of town members be increased to 12/6 and that of country members to 7/6 and that for such increase all members receive the transactions as published.

It was also moved by Dr. Murney seconded by Dr. Patterson that in future there be no reprints of the transactions at the end of the session.

A committee consisting of Mr. Browne, Dr. Murney, Dr. Drennan, Dr. Moore, Dr. Cuming and Mr. Johnston was appointed to arrange to catalogue the museum.

Signed
J. Seaton Reid.
June 9th 1859.

Council Special Meeting June 9th 1859.
Present, Professor Reid, President, in the chair, Drs. Murney, Johnston & Wales.

Mayne's a/c ordered to be paid.

Council Special Meeting September 8th 1859.
Mayne's estimate considered.
Adjourned until 10th inst. at 3 p.m.
Present, Professor Reid, Dr. Murney, Dr. Heeney, Dr. Patterson, Dr. Cuming, Mr. Johnston, & Dr. Wales.

Council Special Meeting September 10th 1859.
Present, Dr. Murney, in the chair, Dr. Halliday, Dr. Patterson, Mr. Browne & Dr. Wales.

Revenue of Society considered, as also expenses of past year with the view to the reduction of outlay.

Mr. Browne moved and Dr. Patterson seconded the confirmation of the motion recommending an increase of annual subscription passed at the Council meeting of 26th May last.

It was also moved by Mr. Browne and seconded by Dr. Patterson that a special general meeting of the Society be called for the 24 inst. at 3 p.m. for the consideration of the Council recommendation viz: the increase of 2/6 to the annual subscription of town and country members, in consideration of their getting the transactions as published weekly or fortnightly and with the view to meet necessary expenses.

Society Special General Meeting to consider the question of subscription. September 24th 1859. Present, the President, Drs. Blakely, Hume, M'Gee, Arnold, Browne, Murney, Dill, Rea, Clugston, Patterson, Heeney, Mulholland, Cuming, & Wales.

In accordance with the Council recommendation it was on the motion of Mr. Browne seconded by Dr. Hume resolved "That *all* members shall contribute, with their annual subscription, the sum hitherto paid for the ordinary weekly abstract (2s 6d), by which the Council will be enabled to issue, during the session, improved reports of the Society's proceedings, in a permanent form, which will then be forwarded to every member."

Council Council Meeting October 22 1859. Present, Professor Reid (President), Drs. Halliday, Pirrie, Heeney, Cuming & Wales.

Arrangements made for the opening of the session on Saturday next.

Advertisements in the local and leading provincial periodical papers ordered setting forth opening of the Society &c.

Circular arranged.

FIRST MEETING
Saturday, October 29th, 1859
at the General Hospital.

The President, Professor J. SEATON REID, M.D., was in the chair.

The following members were present:—Professor Ferguson, Drs. M'Minn, Wales, Dill, Heeney, Mulholland, Ross, Patterson, Halliday, Murray, Reade, Lynch, Moore, Drennan, O'Hare, Dunlop, M'Cormac, Pirrie, M'Mechan, M'Crea; Surgeons Browne, Ross, Arnold, M'Cleeny, &c.

Dr. Cuming, one of the secretaries, read the minutes of the previous meeting, which were confirmed.

Dr. DILL then, according to previous notice, moved that an additional country Vice-president be appointed, so that the number in town and country be equalised. Dr. Heeney seconded the motion.

Professor FERGUSON moved, as an amendment, that the question be deferred till the annual meeting,

and being seconded by Surgeon BROWNE, the amendment passed unanimously.

{Rough minute book: Motherell, Castlederg, was proposed by Dr. Reid.

Moved by Dr. Murney, seconded by Mr. Johnston "That Mayne's proposal for printing be accepted."}

The President delivered the Opening Address as follows:—¹

GENTLEMEN,—*Since the establishment of the Clinical and Pathological Society of Belfast, it has been the custom for the President to deliver an inaugural address at the commencement of each session. It, therefore, now devolves upon me to place before you a few observations of an introductory character.*

I have, in the first place, however, to return my most sincere and grateful acknowledgements to the members of this Society, for the very high honour which they have spontaneously conferred upon me by electing me their President.

This Society was established for the high and noble purpose of advancing medical and surgical science in their practical departments, in the hope of rendering them more efficient for the removal or relief of disease. To preside over the deliberations of gentlemen engaged in so important and vital an object requires such varied accomplishments that I would have been disposed to recoil from the office, had I not been certain of the assistance and support of those who had acted so efficiently as my predecessors, and did I not rely on a continuance of that courtesy towards each other which has hitherto characterised the members of this Society, even when challenging the correctness of each other's views.

The subject matter of an address like the present necessarily varies with the person who holds the office of President. The special branch of practice to which he is devoted, the direction of his reading, and the nature of the questions that at the time agitate the public mind, naturally exercise an influence over the subject he may select for the consideration of his hearers. My professional career having been that of a physician, I have naturally selected for my theme, a subject connected with practical medicine. I have just stated that this Society originated in a desire to contribute to the advancement of medical science; but it is, doubtless, known to you all, that whilst we have claimed for medicine a place amongst the progressive sciences, the validity of our claim has been denied, and it has been asserted, that no progress has been made by it for centuries past. For example, when the late Sir William Hamilton, of the Edinburgh University, reviewed, a few years ago, "Dr. Thompson's Life of Dr. Cullen," he did

¹ [Kindly supplied by Professor R S J Clarke, Honorary Archivist, Royal Victoria Hospital, Belfast. The original was printed in *The Belfast News-Letter* for Tuesday, November 1, 1859.]

not hesitate, after calumniating the members of our profession, to ask, in the most disparaging manner—“Has the practice of medicine made a single step since the days of Hippocrates?”¹

Believing that he and others have acted most unjustly, in denying that our knowledge has increased, I shall, in the following remarks, endeavour to show that, even within the last half-century, a large amount of progress has been made, and that no little amount of benefit has been conferred on mankind by the results.

You are aware that medical science may be defined to be an aggregate of the knowledge we derive from the study of anatomy, physiology, pathology, chemistry, materia medica, and the practice of medicine and surgery. But, it is evident, that were I to go into details respecting the contributions made by each of these, I would far exceed the limits of an address like the present. I must, therefore, endeavour to find some department in which the contributions made by each would appear to be concentrated, and, by a brief and impartial examination of it, endeavour to vindicate our profession against the charges which have been so inconsiderately brought against it.

Now, I believe that you will agree with me in stating that, as the chief object of medical science is the removal of disease, each case presents to the physician two grand problems to be solved. First, to discover its nature; and, secondly, to devise its cure; so that all the benefits resulting from a study of the various branches I have named must be found centred in diagnosis and therapeutics, and are ultimately valuable to us in proportion as they facilitate the recognition and treatment of diseases. That various maladies attack the human body must be admitted by the most superficial and illiterate observer. The records of medicine, in their most imperfect state, recognise this as a fact, and it is employed as the basis of every treatise on medical practice. Diagnosis, or the power of distinguishing these diseases from one another, lies at the very foundation of our art; and just in proportion to the perfection and accuracy of our diagnosis, and our power of discrimination, will be the certainty of our therapeutics, and the attainment of the grand object for which our profession was instituted. Now, if it can be shown that medical science has made progress in the acquisition of knowledge in these two departments, even within so limited a period as the last half century, I conceive it will go far to vindicate our profession against the disparaging charge that has been brought against it.

In attempting the fulfilment of such a task, it is desirable to follow some method or arrangement, and I am not aware that I can suggest a better one than to take as a basis the usual anatomical divisions of the organs of the body, and endeavour to ascertain what improvements have been made in the diagnosis and

treatment of their respective diseases. By this plan, the diseases of the nervous system; next those of the respiratory and circulating systems; then those of the digestive and eliminative organs, will successively be examined.

I shall commence with an examination of the nervous system, rather out of deference to the important place which it holds in the animal economy, than because it is the department in which the greatest progress has been made. That this has not resulted from any want of zeal on the part of our profession, but from the existence of circumstances beyond their control, may be shown by a brief mention of some obstacles that, so far, appear insurmountable. Chief among these may be mentioned the enclosure of both brain and spinal cord in cases of bone, which remove them beyond the reach of any direct examination of their condition, and thus compel the physician to rely almost exclusively upon derangement of their functions as indications of the presence of disease. But our experience of thoracic disease has taught us how little dependence can be placed on derangement of function alone, and what innumerable mistakes we should commit had auscultation not enabled us to test the correctness of its indications. I need but mention, as examples, that the greatest dyspnoea, the most agonising pain, and the most hurried breathing, may be dependent on either functional or organic disease. Again, if distrusting functional derangements, we are disposed to rely upon the statements of the patient, we know that, in many instances, only a very small amount of disease shall have taken place on the surface of the brain, till the mind becomes so confused that no reliance can be placed on the descriptions of the unhappy sufferers. A third obstacle exists in the peculiar structure of the nervous tissue itself. You are aware that this is composed of two materials, called respectively the grey and the white, and that anatomists and physiologists, in their most recent investigations, have endowed each of these with peculiar powers. But they find these structures so intimately blended together that they have difficulty in deciding the boundaries of each; so that, when the pathologist, after a careful observation of symptoms during life, attempts to explain them by organic changes found after death, he is much embarrassed by this structural intermixture. Although an attempt has been made to overcome the first of these obstacles, by the application of auscultation to the brain, yet it has hitherto been barren in results, and I fear that we must look upon them all as belonging to a class that human skill will never be able to remove.

It was necessary to mention the existence of such impediments, in order to protect our profession against a charge of being deficient in zeal; and to account for the want of that precision and accuracy in the diagnosis of diseases of the nervous system which has been acquired regarding diseases in other departments. Still,

¹ Discussions on Philosophy and Literature. By Sir William Hamilton, Bart. 1852. p.253.

the investigations and observations carried on during the last half-century have not been entirely without fruit; and we are enabled to point to several discoveries of the greatest scientific importance, which have rendered our diagnosis more accurate, and extended our knowledge in various directions.

In the first place, we have acquired the power of distinguishing from one another several diseases of the brain that were formerly confounded together. By an application of the law which connects symptoms with lesions, and which led to a closer study and record of the former; and by a subsequent comparison of them with the records of dissections, it was found that diseases very dissimilar in their nature and seat, although similar in their more prominent features, had hitherto been confounded under the same name. For example, there can now be little doubt that, under the name of phrenitis and brain fever, several diseases were described and treated that were in their nature totally distinct, while there were also united under the name of inflammation of the brain, several others, which are now well known to be distinct, both in their seat and in their results.

When inflammation is confined, as is occasionally the case, either to the substance of the brain or to the membranes covering it, we are enabled not unfrequently to tell which is involved; and, when the membranes are the seat of it, to decide whether it be those covering the base or the surface that are diseased—a precision in diagnosis which was assuredly unknown to our immediate predecessors. In the diagnosis of these inflammatory affections we have learned the great reliance that may be placed on our opinion, when either persistent vomiting or sighing respiration, or both, may be present. Whilst our forefathers in medicine would have ascribed the first of these to deranged stomach or biliousness, we have been taught the fearful significance that it gives, in either old or young, to apparently trivial cerebral symptoms; and, if sighing respiration be a less obtrusive symptom, experience has taught us all how to interpret its association with cerebral indications, although these may appear to be of little importance. So indicative of serious brain disease are these two symptoms, that their absence justifies us in holding out hopes of a favourable result to our treatment of others in the same region, which their presence would debar us from entertaining. One of these diagnostic symptoms we have seen manifested by a derangement of the digestive functions, the other through the respiratory system; but there is a third, of equal significance, indicated by the organs of circulation, though of rather less value, because it requires the disease to have reached its last, if not hopeless, stage, before it is fully developed. I allude to the varying frequency of the pulse, first mentioned by Dr. Whytt. Repeated observations have confirmed the accuracy of his remark, that in inflammatory affections of the brain, the pulse is

first frequent, then becomes unusually slow, and again resumes still greater frequency towards the termination of life.

Now, it is not without interest to remark, as a corroborative proof of the difficulties connected with an investigation of the diseases of the brain, that the three chief symptoms which modern research has proved to be the most indicative of inflammation of that organ are learned through a derangement of the digestive, the respiratory, and the circulating systems, rather than from a direct interrogation of the brain itself. I may here state a fact that might be of use on some occasion to some of the junior members of our Society, as I have not observed the point noticed by any authors. Before death takes place from inflammation of the brain in children, there appears occasionally a dusky rash over some parts of the body, which has led the attendant to suppose the child was dying from undeveloped scarlatina. I have known this opinion to have been held with such pertinacity, that whilst the symptoms had been persistent vomiting, constipation, screaming, coma, squinting, convulsions, and hemiplegia, extended over ten or twelve days, yet, in opposition to the opinions of two others, death was asserted to have been caused by suppressed scarlatina, and no other certificate would be given. The more correct diagnosis of these inflammatory affections of the brain has caused the term hydrocephalus to be used much less frequently; as it is now known that the coma, the dilated pupil, and squinting, which were formerly believed to indicate effusion of water in the brain, may be the accompaniments of a mere inflammatory opacity or thickening—effusion of fluid being rather the exception than the rule.

Again, paralysis was formerly described and treated of as a distinct disease, and in almost every instance subjected to the same treatment; whereas now it has been proved to be only a symptom, common to various structural lesions of the nervous centres, such as rupture, inflammation, softening, pressure, &c.; each of which requires a variation in our remedies. And with regard to that form of paralysis that appears occasionally in the insane, it was in consequence of the accurate observations of physicians who practised little more than thirty years ago, that we have been taught to predict an invariably fatal result from the association of the slightest amount of unsteadiness or slowness of articulation with the very mildest form even of mental aberration; repeated observations having proved it to be a law, that the slightest delay in the formation of successive syllables or words by the insane is the certain forerunner of that general paralysis in them which invariably terminates life within two or three years. No remedial measure has hitherto been found to ward off the issue, though lowering treatment has been followed by most injurious results. Now, it is extraordinary that not a trace of a description of this peculiar kind of

paralysis, is to be found in the writings of any physician prior to the year 1822; though it possessed such peculiar characteristics as to be confined almost exclusively to males, to be most frequently associated with that form of insanity in which the patient is always hopeful, the world prospering with him in every respect, his power of motion and his health, in his own opinion, always improving, though he can scarce move or speak. Such patients, also, almost invariably become fat, the very opposite result of the presence of other forms of insanity; yet, with such peculiarities, its natural history was only discovered about the date I have just mentioned.

Within the last few years a peculiar inflammatory affection has been discovered, attacking the base of the brain and superior part of the spinal cord, to which the name of cerebro-spinal meningitis has been given. This, although an acute inflammation, appears to prevail at times as an epidemic, and did so some years ago in the Belfast Workhouse. It most frequently attacks boys, or young men recently subjected to the vicissitudes of a military life.

The foregoing statements have indicated the progress of medical science, by showing that we have acquired much greater facility in the interpretation of symptoms; so that we are enabled, not only to distinguish more accurately diseases of the brain from each other, but also to assert with greater confidence the existence of particular diseases from the presence of certain symptoms, though these latter may not appear to be directly connected with the brain.

I have now to adduce proofs of progress of a somewhat opposite character, by showing that certain symptoms, which at the commencement of the present century were looked upon as infallible evidences of serious, if not fatal, disease of the brain, are now to be interpreted in a very different way. We are indebted for this discovery to our celebrated English physiologist and physician, the late Dr. Marshall Hall. At the period I have mentioned, all diseases were ascribed to inflammation, and it was to the discovery and treatment of it that every physician directed his attention. Pain was known to be one of the most certain indications of its presence in inflammation of the bowels and other localities; and when it was complained of in the head, it was at once held to be indicative of inflammation of the brain, which required the most active blood-letting for its removal. Dr. Hall's great powers of observation soon told him that pain was by no means a certain indication of inflammation of the brain; and that it was almost invariably present when that organ was deficient in blood, rather than overcharged. All who have read his invaluable essay on bloodletting, will recollect his instancing case after case, in which severe pain in the head was but temporarily mitigated by bleeding; but at once relieved by nourishment—brandy and ammonia. To the same illustrious physician are we indebted

for another discovery of a similar nature, as he was the first to point out that a group of symptoms in children, such as insensibility, squinting, and convulsions, which had hitherto been looked upon as certain indications of hydrocephalus, or inflammation of the brain, and requiring the most decided lowering treatment, were in reality the result of exhaustion; and were most certainly removed by brandy nourishment and ammonia. Dr. Watson, of London, has truly remarked that one of the most trustworthy diagnostic symptoms of this peculiar condition of the brain in infants, consists in depression of the anterior fontanelle, the reverse of what occurs when the brain is inflamed. When we recollect the saving of life that has resulted from the discovery of the two foregoing facts, we must admit, that apart from his discovery of the "reflex function," Dr. Hall was entitled to be enrolled amongst the most successful benefactors of his race. Few discoveries of modern times are of greater importance than that which has taught us that exhaustion and irritation may originate a group of symptoms in both brain and intestinal diseases having a great resemblance to inflammation, but which would be aggravated and perpetuated by a lowering treatment, and almost immediately relieved by the reverse. Intimately connected with the brain, are to be found the spinal cord, and certain cerebral nerves; each liable to serious diseases, which, if not so destructive to life as those we have been alluding to, are still of such importance as to cause us to inquire what progress has been made in their diagnosis and treatment.

In connexion with the discoveries in this portion of the nervous system, we may well be proud that Great Britain and Ireland have furnished such experimental physiologists and practical physicians as Sir Charles Bell, Dr. Marshall Hall, and Dr. Bentley Todd. Sir Charles Bell's discovery, in 1811, that the anterior and posterior roots of the spinal nerves performed different functions, enabled an explanation to be given why disease in one part of the cord caused a loss of power, and in another a loss of sensation; and, although the recent investigations of Brown Sequard have shown that he had not succeeded in unravelling all the mysteries connected with sensation and motion, still the accuracy of his original discovery remains almost intact. By Sir Charles's discoveries, also, respecting certain cerebral nerves, we are enabled to explain why, in disease or injury of the seventh pair of nerves, certain superficial muscles of the face are paralysed, and others escape uninjured; and, again, when the anterior root of the fifth is involved, how it happens that the temporal and masseter muscles have lost power, whilst others do not suffer. Two kinds of facial paralysis are met with; one is of trivial importance, almost invariably amenable to treatment, and needs cause little anxiety to the patient; the other is of most serious import, generally dependent on disease of the brain, and too often uninfluenced by treatment. Now, you well know that we are indebted to

the discoveries of Sir Charles Bell and Dr. Bentley Todd for our capability of distinguishing between them; in the one case warranting words of comfort and assurance to the patient; in the other, demanding those of a less hopeful character. Sir Charles's investigations have explained that when the eyelids are incapable of being closed in facial paralysis the disease soon yields to proper treatment, and a permanent recovery results. Indeed, there are few of us who have not found the value of this knowledge, and the relief from anxiety it enabled us to administer to our patients, whose cheeks had become suddenly paralysed. Whilst, on the other hand, by the investigations of Dr. Bentley Todd, we have been taught that the power of closing the eyelids, in a case of facial paralysis, is an absolute proof that the affection is of a more serious character, and depending on disease of the brain itself.

Again, the discovery by Marshall Hall of the propriety of "reflex action," and which has immortalised his name in the science of physiology, has furnished us with unerring means of ascertaining whether the cause of the paralysis of the limbs of our patient is due to disease of the brain, or seated lower down in the cord, thus indicating not only the locality to which our remedies should be applied, but furnishing us with the means of deciding on the propriety of using that most powerful remedy, strychnine, which is beneficial when the spinal marrow is the cause of the paralysis, but hurtful when the brain is diseased. Although this knowledge had been acquired within the last quarter of a century, yet some recent investigations of Professor Van Der Kolk have extended our knowledge of the reflex function, by demonstrating that the posterior roots of the spinal nerves divide in the spinal cord into two parts, one of which passes directly up to the brain, and is the channel of sensation; whilst the other penetrates through the white masses of the cord into the grey substance, and becomes the channel through which the phenomena of the reflex action are excited. I might add to the foregoing other examples of improvement in our diagnosis of other diseases of the nervous system, but I have limited myself to a notice of the most important conquests that have been achieved; conquests which have been acknowledged by the most enlightened practitioners in every country, and by them admitted to have contributed to the preservation of human life.

Such, gentlemen, is the reply that an examination of even one portion of the diseases of the human body enables us to present to the detractors from our professional renown. And when we recollect that some of the most important of those discoveries were made by Sir Charles Bell in Edinburgh; that they had procured for him so world-wide a reputation, that no disease of the nervous system could be mentioned without his discoveries being noticed; that he was the co-professor of Sir William Hamilton in the University of Edinburgh; and that Scotchmen are generally not insensible to the

claims of their countrymen, we are at a loss to account for the utterance by Sir William of such a calumny on our profession as "that medicine in the hands by which it is vulgarly dispensed is a curse to humanity rather than a blessing,"¹ or for his addressing to us the question, "Has the practice of medicine made a single step since the days of Hippocrates?" When language like this is published by a writer of such unquestionable attainments in philosophy, and attempted to be justified by quoting a statement of the blacksmith Priesnitz, of water cure celebrity, surely we must accuse him of having shown a most unpardonable ignorance respecting the history and progress of medical science, or conclude that his mind had become warped by a most unjustifiable prejudice against it. But, I must remember that Sir William is no more, and that—

De mortuis nil nisi bonum.

The plan which I had laid down for my inquiry into the progress of medical science, requires me next to ascertain what improvements have taken place in the recognition and treatment of diseases in the organs of respiration and circulation. I am certain that you will agree with me in stating that it is here that the practice of medicine has achieved its greatest triumphs, and that we are enabled to enumerate discoveries in diagnosis and therapeutics that half-a-century ago would not have been deemed possible by the most enthusiastic member of our profession. It is almost superfluous to state that these have resulted from the application of auscultation and percussion in the investigations of all diseases of the lungs and heart. Auscultation in medicine, you are all aware, is the art of listening to the different sounds produced in the living body; and, as a method of diagnosis, it has for its object to determine the condition of an organ in which the natural sounds are altered. Its application to the study of diseases of the respiratory and circulating organs proved it capable of rendering the diagnosis of nearly every disease of the lungs, of the pleura, and of the heart more certain, and more minutely accurate, than perhaps even those diagnoses established by means of the sound, the probe, or the finger. For the discovery of this valuable and useful art we are wholly indebted to the immortal Laennec, and at a date so recent as 1816. Not only did he lay the foundation of our knowledge respecting it, but, by his indefatigable industry and ardent zeal, he brought it very nearly to that degree of perfection which it has now attained, and which renders it one of the most efficient means ever devised by the skill of man for the elucidation of pulmonary and cardiac affections. The stethoscope enables the physician of the present day, as it were, to see through the body of the patient, and to announce, in the great majority of instances, what alterations of structure exist at the point which is subjected to his examination. No intelligent

¹ Discussions on Philosophy, &c. p. 252.

practitioner can now refuse to acknowledge that the discovery of auscultation, by this eminent Parisian, forms one of the most memorable eras in the history of medicine; nor will its practical utility be denied by any one who has qualified himself to estimate its value. Whilst we have claimed for our countrymen, Sir Charles Bell, Dr. Marshall Hall, and Dr. Todd, some of the most valuable discoveries in connexion with the nervous system, we must, in candour, acknowledge that the entire merit of the discovery of auscultation is due to the illustrious Frenchman, although, as an art, it has been greatly extended and more accurately applied by Drs. Stokes, Williams, Walshe, Corrigan, and Hope. It has rarely happened, however, that there has been an instance of a discovery of equal importance in which so little was left by the discoverer to be performed by others; and we, who have benefited so much by his genius, cannot but rejoice that, as an exception to the general rule, the gratification was enjoyed by Laennec of witnessing the acknowledgment of the value of his discovery, and its adoption by the most intelligent of his countrymen and contemporaries.

Exactly a century ago an Austrian physician had announced the discovery of a new means of detecting the diseases of the lungs and the heart, to which he gave the name of percussion. This discovery attracted little attention, and had fallen into oblivion till about the year 1808, when Auenbrugger's treatise was translated into the French language by Corvisart. The value of percussion was soon tested, more extensive applications of it proposed, and, under the distinguished Piorry, of Paris, it has been brought to a high degree of perfection as a means of diagnosis. He, however, appears to place too exclusive reliance on this method, and professes to obtain results with his pleximeter which others of equal ability and honesty are quite unable to confirm. Still it must, in candour, be admitted that many who have accompanied him in his visits to his hospital patients have been astonished at the accuracy of his diagnosis. The most ignorant vender of whiskey or beer knows how to estimate the gradual falling of the liquor in a cask, by the different sounds elicited on striking it above and below the level of the liquid. In like manner, every part of the human body, when struck, emits a certain sound, and always the same sound under the same circumstances, and, therefore, when found altered by disease, it becomes a valuable symptom. Ordinary percussion is chiefly used to ascertain the degrees of intensity of sound, or, in other words, the degrees of sonorousness or clearness, and their opposites—dulness or flatness. It, however, reveals only one symptom, and but one element of diagnosis; although that symptom is often of paramount importance, yet it rarely, if ever, is of itself sufficient for determining the nature of the disease. If, for example, percussion discovers dulness at the base of a lung, other means must be employed to discover its cause. In such a case, it

merely indicates that a comparatively dense body occupies the place which in health is occupied by a substance of lesser density. If we wish to know more, auscultation and the general symptoms must determine what the nature of that body is, and how it affects the general system. When auscultation and percussion are thus combined, they become invaluable in diagnosis; in fact, they are essential to the successful practice of medicine, nor can either be relied on to the exclusion of the other. Their mutual dependence is so well known to you all that I need not mention many examples. But, having given one illustration of the insufficiency of percussion without the aid of auscultation, I may, in justice to Auenbrugger, give one where percussion is as necessary in aid of auscultation. Certain circumstances cause the stethoscope to be applied over the right lung, but no sound whatever of respiration can be heard. Is the lung solidified, or is the pleura full of fluid? Auscultation cannot furnish a reply, because no respiratory sounds are heard, either healthy or morbid. The aid of percussion is sought to clear up the difficulty, and it finds perfect, or even unusual, clearness of sound; therefore, neither solidification nor effusion can exist. There must be some cause preventing the air passing into or out of the lung, and a reference to the patient's history may furnish good grounds for believing that a foreign body blocks up a bronchial tube, thus rendering the passage of the air through the lung impossible, and, consequently, stopping all sounds. This body may be a "wisdom tooth," as in the late Dr. Houston's patient, or a half-sovereign, as in the case of the celebrated engineer, the late Mr. Brunel. The idea of combining auscultation and percussion originated with Laennec, proving that he desired progress in medical science rather than fame for himself, by an exclusive advocacy of auscultation.

Percussion, I have said, had been proposed as a means of distinguishing diseases of the chest fully a century ago, but it attracted little notice, and had fallen into oblivion till Corvisart recalled attention to it in Paris in 1808, and it was little practised in England till 1824. Whilst, therefore, it cannot, like auscultation, be claimed as a discovery of the last half-century, still to the physicians of this period is due the merit of its application, and a more accurate and extensive appreciation of its value.

I make no apology for this allusion to the discovery and history of auscultation and percussion; because, in common with every practical physician, I witness daily the incalculable benefits they confer on mankind, and feel that medical science can most truthfully point to both, as discoveries of recent date, which exercise an unquestionable influence in the relief of human suffering and the preservation of life; in this way accomplishing the noble purpose for which our profession has been organised. And if any sceptic wishes to be convinced of the great progress that the practice of medicine has made since the introduction of these methods

of investigation, it is only necessary to contrast the facility of discriminating the most frequent pulmonary affections at the present time with the difficulty which confessedly existed prior to the employment of those methods. If we turn to the works of Cullen, in praise of whom Sir William Hamilton could find no language sufficiently eulogistic, or to the more recent writings of Good or Thomas, we will find that these authors acknowledge the inability of the practitioner to distinguish, by means of symptoms, pneumonia, pleuritis, or bronchitis from each other. At the present time, by associating auscultation and percussion with other symptoms, it rarely happens that the discrimination cannot at once be made. And that this improvement is mainly due to these newly-discovered aids in diagnosis is shown by the fact that, to distinguish the affections referred to by symptoms alone, is still as difficult as it was to the physicians I have named. If any one ascribes our success to a more accurate interpretation of mere symptoms, it is sufficient to refer to the mistakes in diagnosis daily made by practitioners who rely exclusively on symptoms; mistakes which might be easily avoided by their practising auscultation and percussion. Bronchitis, pneumonia, and pleuritis, are not unfrequently latent, so far as distinctive symptoms are concerned, and consequently overlooked; or they may be completely masked by the symptoms of other associated affections, and thus escape detection. Of this we have daily examples in fevers and in head affections of both children and adults. But the application of auscultation and percussion at once enables the modern practitioner, if properly qualified, to arrive at a correct conclusion as to their existence.

Chronic pleurisy was habitually mistaken for other affections by the physicians of former times, and still is mistaken by those who do not practice auscultation and percussion; and yet nothing is now more simple than to determine the existence of this affection by these new methods of investigation. In illustration of how much we are indebted to these methods for improvement in the accuracy of our diagnosis, let us examine for a moment the value of the definition given of acute pleurisy, by the late Dr. Good, in these words:—"Acute pain in the chest, increased during inspiration; difficulty of lying on one side, hard pulse, short distressing cough." Is there a physician who would now accept this as a definition of the disease, or from the presence of these symptoms state that it existed? You all know that he would not, and for the simple reason, that the use of his stethoscope and percussion have taught him that the disease may exist without any of these symptoms, and, what is of more importance, that if they were present, they may indicate the existence of pericarditis rather than pleuritis. How different is the accuracy of our diagnosis of acute pleurisy, as revealed by auscultation and percussion. This will be best shown by a rapid sketch of what they indicate as taking place in

such a case. A patient complains of his left side. The symptoms I have quoted from Dr. Good may or may not be present. His physician immediately applies his stethoscope, and through it hears the sound, as of two rough surfaces rubbing over each other; percussion at first finds no dulness. In a few days the rubbing sound ceases to be heard, and it might be supposed that the disease had disappeared, were it not that percussion now detects dulness, owing to effusion of fluid, where clearness previously existed. Day after day this is found increasing in extent. The sounds of the heart now cease to be heard through the stethoscope in the region of the nipple, but are heard underneath, or to the right of the sternum, and can be traced daily passing gradually across till they are heard on the margin of the right arm-pit. In a few days more, the patient has been brought under the influence of medicine, and the fluid which had dislocated the heart begins to be removed; then, day after day can the heart's progress back to its natural position be traced by auscultation, till in a short time, by means of auscultation and percussion combined, we can assert that all fluid has been removed, and the lung has been enabled to resume its natural functions. There are few present whose experience could not verify the description I have given, and all are aware that the information thus obtained may be implicitly relied on, even should the patient's mind be so utterly prostrated as not to be able to answer a single question. It is known to you all that, for any such accuracy in diagnosis, or history of a case of acute pleurisy, we would search in vain the works of either Cullen, Thomas, or Good; yet this accuracy of knowledge is now possessed by every well-educated physician, though he should only have just completed his education.

It is unnecessary to make similar special remarks regarding the accuracy of our diagnosis of pneumonia, bronchitis, and other diseases of the lungs. Indeed, the value of auscultation and percussion might be illustrated by almost innumerable instances, but I shall only notice a few general examples of their utility. By them we are enabled to distinguish at once between organic and functional disorders of the respiratory organs; to detect serious lesions, while their functions seem almost unimpaired; to determine the precise situation of the lesion, its stage, and extent; to indicate the proper place to which our remedies ought to be applied, as well as to prevent error in their selection, by establishing that essential preliminary to all successful treatment—a correct diagnosis.

Acknowledging, to the fullest extent, the discoveries that have resulted from the application of auscultation and percussion to the investigation of the diseases of the lungs, we are constrained to admit that they have been surpassed in novelty and extent, if not in accuracy, by those that have resulted from the use of these new methods in recognising and distinguishing dis-

eases of the heart and large blood-vessels. These diseases were imperfectly understood until within a comparatively recent period—almost within the last quarter of a century. Formerly, they were thought to be very rare, and, because not recognised till their advanced stages, were considered to be almost uniformly fatal—a popular impression which has still such hold on the public mind as to require extreme caution in announcing their existence, They often escaped detection altogether, in consequence of the attention of the practitioner being directed to other prominent morbid affections, such as congestion, and hæmorrhage from the lungs, cerebral apoplexy, and different forms of dropsy, of which they were in reality the primary cause; but which, from an ignorance of auscultation, there was no means of detecting. For, if it has been successfully shown that general symptoms are insufficient to enable us to detect diseases of the lungs, we may, with tenfold accuracy, assert their incompetency with respect to diseases of the circulating organs, as every practical physician is aware that, where they would seem to point unerringly to the presence of organic disease, it may not be present; and, even when it is present, no general symptom might indicate its existence.

Formerly, as I have said, the diseases in question were considered to be rare, and almost uniformly fatal; now they are known to be very frequent; but, if treated in their early stages, they are found, though dangerous, to be by no means uniformly fatal, nor entirely beyond the control of medicine. The facility with which the stethoscope enables us to detect these diseases, and to announce their presence, has caused non-professional persons to imagine that diseases of the heart were surely becoming more frequent. Recently they have been ascertained to be so associated with, and dependent upon, certain diseased conditions of the fluids of the body, that the early application of therapeutic measures to the latter has repeatedly been successful in preventing them.

Great as we have found the revolution produced by the application of auscultation and percussion to diseases of the lungs, it is undoubtedly greater and more important in connexion with diseases of the circulating organs; for these methods have revealed to us diseases, the very existence of which was previously unknown, and enabled us to detect them in their very earliest stages, and before a single feeling on the part of the patient or a single constitutional symptom had given warning of their presence. And if there be here to-day any member of this Society who is disposed to disparage the value of auscultation, I would ask him could any of our forefathers in medicine have detected in a single instance the existence of acute inflammation in either the lining or the covering membrane of the heart? We know well they could not; and that, even with reference to the most frequent cause of inflammation in both these localities, the only extent to which

observation of symptoms through thousands of years had increased their knowledge was, that disease of the heart followed so often on acute rheumatism that they appeared to stand towards each other in the relation of cause and effect. But to tell at what period the heart became diseased, with what morbid process it commenced; in what texture of the organ it had originated, or how its presence was to be detected, was to them impossible.

How entirely has the application of auscultation removed this professional ignorance and incompetency! If we see a patient at the commencement of an attack of acute rheumatism, before the heart becomes involved, we can, by the aid of auscultation, tell almost the very hour in which inflammation will commence. We can tell, in the overwhelming majority of instances, whether it is seated in the interior or the exterior covering of the organ. If in the interior coating, we can tell whether it is the orifice through which the blood enters, or that through which it leaves the heart, that is involved. We can tell whether the disease only obstructs the passage of the blood from the heart, or whether it has so disorganised the valves as to render them incapable of preventing the regurgitation of the vital fluid.

For this precision in our diagnosis, we are chiefly indebted to the labours and observations of Bouillaud, in France, and in England, to those of Williams, Hope, and Latham.

Again, if the exterior covering be attacked, the same sound of two roughened surfaces passing over each other which auscultation detected in acute pleurisy, is found to exist here also. This friction sound may, as in pleurisy, disappear in a few days, and the same erroneous conclusion might be formed as to the cessation of the disease, did not percussion inform us that the natural dull sound over the heart had become extended over a larger space, indicating an accumulation of fluid round the heart. In a few days the patient has been brought under the influence of medicine; the removal of the fluid commences; and when it has so far disappeared as to allow the roughened surfaces to approach each other, we have a return of the rubbing sounds for a short period, and then, by the conjoined application of percussion and auscultation, we learn that all morbid indications have ceased, and that all immediate risk to life is over.

Now, this knowledge has been acquired within the last quarter of a century, and it is with feelings of no little gratification that we can point to it as the result of the genius and industry of our illustrious countryman, Dr. Stokes.

But the value of auscultation is not confined to acute cases alone. Many of you, like myself, have been asked to visit a patient who thought “he had caught cold.” Every portion of the lungs is explored with the stethoscope, without finding any disease. At last a faint murmur is heard over one of the large arteries; it is

traced to its origin in the heart, and reveals the existence there of deadly disease, of old standing, the patient being all the while ignorant of its existence, and unconscious of any illness in which it originated. If asked of what value is the discovery of this incurable disease, which is causing no inconvenience? I reply that, apart from the scientific interest connected with its detection, it may be of vital importance to the patient. With a knowledge of its existence no intelligent physician would apply those debilitating remedies which, under other circumstances, might be applied with propriety. Nor could he forget, in the treatment of such a patient, that

Hærit lateri lethalis arundo.

The examples I have given have shown the value of auscultation in the detection of diseases of the heart; but it is of no less importance in a group of cases in which certain symptoms and sensations in a patient lead him to believe that he is the subject of disease, when in reality he is not. These symptoms often imitate very closely those of real disease, and occasion much mental distress and anxious apprehension to the subject of them, lest he may be labouring under an incurable affection. I am certain that there are few members of this Society who have not had opportunities of removing such mental disquietude by the application of the stethoscope, which enabled them to assure their patients that there was no evidence of organic lesion.

Time will not permit me to furnish illustrations of the great improvements that have taken place in our power of detecting those diseases of the substance of the heart and of the large blood-vessels, which are developed in the enlargement, the softening, or the conversion into fat of the former, and in the dilatation into aneurisms of the latter. In the discovery of these, our countrymen, Dr. Stokes, Dr. Corrigan, Dr. Greene, and Dr. Bellingham, have all borne a most distinguished part, having extended our means of diagnosis, and contributed rules for their treatment, that in practical utility could not be surpassed. I am certain that you will not have forgotten how unhesitatingly the indebtedness of our profession and of mankind to Laennec, as the discoverer of auscultation, has been admitted, and also the great perfection to which he had brought its application in investigating diseases of the lungs; but truth compels us to acknowledge that he was not by any means so successful in his application of it to the diagnosis of diseases of the circulating organs; inasmuch as many of the diagnostic symptoms and rules which he inculcated have been found by his successors to be quite incorrect. This, you are aware, was owing to the inaccuracy of the knowledge of his day respecting the motions and sounds of the heart, and not to a want of accuracy of observation on his part. In fact, the order in which the contraction of the various parts of the heart took place, and the cause of the sounds that were heard, were not ascertained till many years afterwards; and in

their elucidation Professor Carlisle of Queen's College, Belfast, took a most active part.

The high state of perfection that has been reached in the diagnosis of diseases of the heart and large blood-vessels has resulted from the researches and discoveries of Laennec, Corvisart, Collin, Louis, and Bouillaud, in France; of Hope, Williams, and Latham, in England; of Stokes, Corrigan, Green, and Bellingham, in Ireland. Nor do I consider that I am detracting from the merits of British stethoscopists, if I assign a pre-eminent position amongst them to our countryman Dr. Stokes. He has shown himself to be a master in the diagnosis of disease of both the heart and of the lungs—in the former discovering almost all that we know of pericarditis and fatty degeneration; in the latter, the differential diagnosis of intra-thoracic tumours. Indeed, by his discoveries and published works on the diseases of the respiratory and circulating organs, he has earned for himself a position in the history of auscultation, only second to that of the immortal Laennec.

Whilst referring to what we owe to distinguished men in our own and other countries, in this department of medical science, we may observe, that we are not aware of any contributions Scotland has furnished to it by any of her physicians, or the professors in her universities or colleges. Dr. Hope, who wrote so ably on diseases of the heart, was, indeed, born in Scotland, but he pursued his investigations into cardiac diseases in England; so that we think it will be found, that all the really valuable additions which have been made, out of France, to the diagnosis of the diseases of the lungs and heart, have resulted from the researches of either Englishmen or Irishmen, in which investigations, Ireland's sons have borne no inglorious part.

We must not, however, forget how much our therapeutic knowledge has been advanced by the zealous and judicious manner in which Dr. Bennett, of Edinburgh, has introduced cod-liver oil as a remedial agent in the treatment of thoracic and other diseases.

I have now terminated my inquiry into the progress that has been made in our knowledge of diseases of the lungs and of the heart; and I believe that I am justified in stating that if medical science could indicate no other discoveries than those I have mentioned, they are abundantly sufficient to prove that the slander that has been published against us was unfounded and unjust. More numerous proofs of advancement could have been given, had I not been compelled to limit myself to an enumeration of some of the most prominent, the value and accuracy of which have been admitted by the most intelligent and trustworthy physicians in every country. I must add that the largest exercise of charity cannot reconcile us to the opinion that a discovery like auscultation and the stethoscope, which was the theme of conversation amongst all classes in the community, and which had its aid invoked by the highest and wealthiest in the land, as well as by the poorest of the

poor, could have been so utterly unknown to the reviewer I have named, as to warrant his asking the disparaging question—“Has the practice of medicine made a single step since the days of Hippocrates?”¹

I have next to inquire into the improvements that have been effected in the diagnosis of the diseases of the digestive and eliminative organs. Many asserted discoveries in this department have not yet received the assent of the majority of physicians; and as in my examination of the nervous, respiratory, and circulating systems, I only noticed such discoveries as had met with general acceptance, a similar course here will render my notice a very brief one. Notwithstanding the increase to our knowledge of the physiology of digestion that resulted from the observations and examinations made by Dr. Beaumont, through the valvular opening in the stomach of the Canadian, St. Martin, we are still compelled to admit that little, if any, improvement has taken place in acquiring a more accurate diagnosis in the diseases of the stomach. Some progress has, however, been made in distinguishing the inflammatory diseases of the intestines. The researches of the late Dr. Abercrombie have shown that inflammatory pain, when associated with a loose state of the bowels, may be, in the majority of instances, accepted with considerable confidence as indicative of the mucous coat of the intestines being involved; that pain, if accompanied by a constipated state of the bowels, may be interpreted as symptomatic of inflammation of the muscular coat; and again, that when the inflammation is limited to the peritoneal coat there will be pain, soon followed by dullness on percussion, and that the bowels may be either loose or constipated. Previous to those investigations of Dr. Abercrombie, all the inflammations of the bowels were included under a common name, and the peritoneum supposed to be frequently involved, when the mucous membrane alone was affected, it being now well ascertained that the serous and the mucous tunics of this organ are rarely involved in the same acute inflammation, except when occurring in the puerperal state.

With respect to chronic inflammation of the peritoneum, an interesting application of the law of tubercular development was found to apply. Louis had observed, during his researches into tubercular disease of the lungs, that if, after the age of fifteen years, tubercles, or grey semi-transparent granulations, were found in any organ, they existed at the same time, in a more advanced stage in the lungs. And, as chronic peritonitis, occurring subsequently to the age of puberty, is always tubercular, an application of the law just stated indicates that that disease is always associated with tubercles in the lungs, although their numbers or development may not have intimated their presence. The well known accuracy of Louis's observations requires us

to admit this as a fact, and it should never be forgotten in the treatment of chronic peritonitis, for it at once prohibits the use of mercury, which has been found of such unquestionable value in the treatment of the acute disease. The only eliminative organ in the abdomen, in which the diagnosis of its diseases has made undoubted progress, is the kidney. About a quarter of a century ago, Dr. Bright discovered that this organ was very frequently the subject of disease, which gave origin to a number of other secondary diseases that, previous to his investigations, had never been supposed to be in any way connected with the kidney. This state of the kidney he considered capable of being ascertained by a diminished specific gravity of the urine, but especially by the presence of albumen in it.

A considerable amount of discussion and investigation, continued even to the present day, followed his announcement of this hitherto unknown disease. Some have differed with him respecting its nature, others as to the pathognomonic value of the diagnostic symptoms he had announced. All, however, are unanimous in acknowledging the kidney to be liable to a disorganisation previously unknown, and that its detection depends on an examination of the urine. In honour of the discoverer, it has received the name of “Bright's Disease,” which will perpetuate the name of this distinguished physician, like that of Mr. Pott, through all future ages of our profession, and mark him as one of the most accurate observers of symptoms during the lives of his patients, and a successful tracer of them to their cause after death.

It is not without some interest to remark, in passing, that notwithstanding Dr. Bright's unlimited zeal in examining patients when alive, and their bodies after death, yet he possessed so little moral courage, that when ill himself, he would permit no minute investigation to be made into the nature of his disease; so that, although he had the advice of some of the most eminent physicians of the metropolis, yet from compelling them to rely upon mere symptoms in the formation of their opinion, he died without his disease being detected, although the examination of his body after death proved that the application of the stethoscope would have revealed it in a few seconds.

But, to return to the diagnosis of Bright's disease of the kidney. If some recent statements be verified, there would at last appear a means of reconciling the conflicting opinions and statements I have alluded to, and of establishing some most valuable symptoms for diagnosis. The researches of Dr. George Johnston and Dr. Wilkes, some years ago, conjoined with the recent investigations of Mr. Dickenson into the particulars of a large number of cases treated at St. George's Hospital, appear to have proved that there are two forms of diseased kidney to be met with under the name of Bright's disease, and that each of these possesses peculiar diagnostic symptoms, amongst which Mr. Dickenson now

¹ Op. Cit. p.252.

wishes us to include the age of the patient. First, there is an enlarged kidney with a smooth surface, in which it is the secreting surface of the tubes that is deranged. The diagnostic symptoms of this form are stated to be scanty urine, with a specific gravity above 1,015, much albumen and coarse granular tube casts; considerable dropsy; the average age of fatal cases being 28 years. In the other kind, the kidney is contracted, granulated or lobulated on the surface, and the disease seated in the tissues between the tubes. The diagnostic symptoms of this form are stated to be a rather abundant secretion of urine, with a specific gravity below 1,015; little albumen; some transparent tube casts, loaded with fat or oil; little dropsical effusion, and the average age of fatal cases 50, the patients being often gouty. My own experience leads me to believe that this new classification and indication of the symptoms peculiar to each may be relied on in practice, if we take care to separate those cases in which the urine contains albumen, in consequence of impeded circulation through the heart.

Here, again, we have another example of the discovery of a new disease and its diagnostic symptoms, resulting from the observations and researches of physicians within a comparatively recent period. Nor must we forget that Dr. Christison, colleague of Sir William Hamilton in the Edinburgh University, took a very distinguished part in indicating the secondary diseases that most frequently appeared during the progress of Bright's disease; whilst Dr. George Johnston, and, more recently, Dr. Basham, have most successfully applied the microscope in detecting the various kinds of casts and transudations that are found present in the urine during the course of this disease. Indeed, the latter asserts that greater dependence can be placed on the revelations of the microscope than on those other diagnostic marks hitherto relied on.

The recent researches of Dr. Addison, of London, have directed the attention of physicians to a diseased state of the supra-renal capsules, and to a frequent association with it of a peculiar discolouration of the skin, and a state of great constitutional languor and debility. As yet, however, it has not been proved that these exist in the relation of cause and effect; nor has much practical utility resulted from the discovery.

I have now passed in review the more important discoveries that have been made during the last fifty years, in connection with the diseases of the three great anatomical divisions of the human body. In all of them we have found evidence of additions to the knowledge of the practice of medicine, that could not have been anticipated at the commencement of this century. There are few amongst us who have not read the terms of derision in which all the leading journalists received the announcement of what auscultation and percussion proposed to effect; and we now know that they vie with each other in proclaiming their success. Notwithstanding the physical obstacles opposed to a minute invest-

igation of another department, we have found discoveries effected of the very highest importance, and conjoined with a more accurate interpretation of symptoms in their diagnostic, therapeutic, and prognostic relationships; all contributing to the preservation of life. And, lastly, we have had revealed the existence of a most fatal form of disease in one of the eliminative organs, and its diagnostic symptoms established on a most certain and accurate basis. With such indisputable evidence of progress in the practice of medicine, are we not justified in appealing to every impartial mind, whether a satisfactory reply has not been furnished to the defamatory remarks which a high name has circulated against us.

Had time permitted, I might have alluded to the glorious termination to the investigations of the physicians of the last century in the discovery of vaccination by the immortal Jenner, in 1796, which is estimated to save at least 500,000 lives each year, and which, if unacknowledged by the reviewer I have named, had elicited from the savage chief of the Indian tribes, the following most striking language:—"We shall not fail to teach our children to speak the name of Jenner, and to thank the Great Spirit for bestowing upon him so much wisdom and so much benevolence." I might have alluded to the labours of Howard, the philanthropist, a member of our profession, who has effected such an annual saving in human life by his reformation in the management of jails and lunatic asylums. I might have instanced the saving of life that has resulted from the practice of medicine in its obstetrical department, so that the mortality from child-bearing has been reduced from one in fifty to one in two hundred; and that, from a better management of children's diseases, and attention to hygenics, 100,000 lives are now annually saved, when compared with the mortality that prevailed among children less than two centuries ago. And, finally, I might mention the prolongation of human life generally in these countries, resulting from a more successful treatment of diseases, and from the adoption of various sanatory arrangements, first suggested, by our profession; so that, whilst it is known that one in every twenty-one of the inhabitants of England and Wales died annually about a century and a-half ago, now the bills of mortality only indicate one in every forty-five.

I had originally intended to have entered more minutely into these subjects, and to have reserved a portion for a closing address. I feel compelled, however, to condense both addresses into one, and to indicate only the more prominent discoveries in our science. I trust that enough has been said to establish for medicine a valid claim to an unquestioned position amongst the progressive sciences. I have only to regret that the enumeration of the proofs of its advancement, and the defence of its practitioners from the slanders that have been published against them, had not devolved upon one more competent to the task.

Belfast Clinical and Pathological Society
Seventh Session: 1859–1860
President James Seaton Reid

Gentlemen, the value of a society like this to ourselves, as well as to the public, the spirit that should influence our proceedings, the necessity for each member exerting himself to promote its success, have all been so well placed before you by others, that it would be a work of supererogation did I dwell on them again. Aware that my position as President renders it undesirable that I should be a frequent contributor to your proceedings, I have to hope, that the Session we now enter upon shall be productive of such varied and valuable communications from you all, as to prove that your zeal, industry, and anxiety for the prosperity of this society have in no degree diminished.

I enter on my duties, pleading for an extension of your forbearance, in consideration of my many shortcomings, and with unfeigned anxiety, lest anything should occur that would in any way check the hitherto prosperous career of this society.

Need I add, how desirable it is that all possible courtesy should be extended by you towards each other during debate, so that when the session closes we shall separate with those feelings of mutual esteem and respect which it is desirable should exist among the members of a profession that has been organised in harmony with the commands of the Great Physician to His disciples, when He said—“Into whatsoever city ye enter, heal the sick that are therein.”

Having such an authority for the practice of a profession which exercised the sympathies of even Divinity itself, I shall close in the not inappropriate language of an eloquent historian of medicine, who says—“Who of us shall forget its ever-living charities; its moving scenes of joy and sadness; its many sunny aspects; its benignant, ennobling, liberalising influences; which few beyond our own circle can properly appreciate, and none so well understand as ourselves.”

{Rough minute book: Moved by Mr. Browne seconded by Dr. Moore “That the address would be published.”}

It was moved by Dr. FERGUSON, seconded by Dr. MOORE, and resolved, “That the Address of the President be published as part of the Transactions.”

The PRESIDENT then presented to the members a handsomely-framed engraving¹ of the late Dr. Malcolm, Founder of the Society. He was sure his departed friend required no eulogium here, as he lived in the memory of them all; but he hoped that his example would excite them to emulate that zeal which was so characteristic of him.

{Rough minute book: Moved by Ferguson seconded by Browne “That the thanks be given for Dr. Malcolm’s portrait.”}

¹ [The image of Malcolm currently in the possession of the Ulster Medical Society seems to be a photocopy. The whereabouts of the original is unknown.]

Council Council Meeting November [2nd] 1859.

Present, the President, Surgeon Browne, Drs. Dill, Cuming, & Wales.

The President read a letter from Dr. Browne of Derry in which the writer stated “that he had been elected a member of the Society two years since, and had received some of the weekly reports, but that through the misadventure of a friend to whom he gave his subscription it had never been forwarded. He therefore enclosed two years subscription.” It was arranged that if Dr. Browne’s name could be found in the minutes as having been proposed and seconded that he should not again be submitted to proposal and ballot but that his subscription for two years be received and that he shall receive the transactions for the past year.

Enlarging the size of the type and paper of the transactions was considered and it was resolved to make no change.

The circular was prepared as follows. To be discussed the medical journal or journals in which it will be advisable to publish the transaction of the Society.

The ballot to be taken for John Motherwell M.D. (Edin.) L.R.C.S. (Edin.) Castledearg, C^o. Tyrone.

To be proposed Samuel Hunter M.D. Edin. L.R.C.S.I. Belfast.

Morbid exhibits. Recent parts in elephantiasis, case of enlarged nymphæ of clitoris. Case of aggravated hysteria.

SECOND MEETING.

November 5th, 1859.

The President in the Chair.

{Rough minute book: President, Dr. M’Gee, Patterson, Ross, Corry, Wales, Heeney, Halliday, Mulholland, Browne, Dill, M’Cleery, Arnold, M’Minn, Warwick, W. Aickin, Murney, Murray, Ferguson, Rea.

Dr. Motherell elected.

Dr. Hunter seconded by Dr. Ferguson, proposed by Dr. Reid.

Moved by Dr. Ferguson seconded by Mr. Browne that Dr. Hunter be admitted as country member.

Dr. Connor by Dr. Halliday seconded by Dr. Mulholland.

Dr. Buckingham by Dr. Halliday seconded by Dr. Corry.

Moved by Mr. Browne seconded by Dr. Patterson “That transactions be published in the Dublin Gazette.”

Moved by Dr. Halliday seconded by Dr. M’Gee “That the transactions be continued to be published in the Dublin Hospital Gazette.” Passed.}

Mr. BROWNE introduced a patient on whose foot he had recently performed an operation. This man, S. G., aged twenty-two, some four years ago, first suffered from strumous disease. He then had a tumour over

the carpal end of the radius, which, after some time, suppurated. Three years after, ten months since, he felt pain over the metatarsal bone of the great toe of right foot. This part became enlarged, and finally suppurated. On examination, the metatarsal bone and first phalanx of the great toe were found to be in a necrosed state, necessitating their removal. Seven weeks since the parts were amputated, and the wound healed up kindly. He now walks well, and with a very slight halt in his gait.

While under treatment, a portion of the radius was found to be necrosed; this was removed, since which the open sore, of several years' standing, has completely cicatrised, and the man's health, formerly very bad, has been quite restored.

Case of Elephantiasis.

By Dr. Babington, Surgeon, Londonderry Infirmary.

(Read by Dr. Cuming.)

H. S., the subject of accompanying drawings, was admitted into County Londonderry Infirmary, 15th August, 1855, presenting the appearances accurately delineated, and sketched soon after his admission.

He did not complain of any particular disease, but wished to have something done to his leg, the weight of which caused him much annoyance.

He was a man of weak intellect, and could give but an imperfect account of the commencement and progress of his case. The following particulars are all which could be obtained:—Aged thirty-six years. Disease commenced in the skin of his back, over the lower part of the spine, when fourteen years of age, and gradually increased to its present size, as represented in the drawing. His leg began to enlarge about ten years since, and the tumours, scattered over the chest and trunk, appeared at intermediate periods—those on the face and neck since the leg began to enlarge. The leg measured twenty-seven inches in the centre of the swelling, which was quite loose, without any deep attachment, and rolled about from side to side over his foot, the skin of which was natural in appearance. An ulcerated opening existed in the lower part of the tumour, from which an ill-digested sanious discharge flowed in small quantities. He complained of no pain either internally or externally; his urine presented no morbid indication; there was no evidence of any internal organic disease, with the exception of the left side of the chest, in which no respiration could be detected. He complained of weakness, and suffered from occasional attacks of diarrhoea. He remained in hospital till December 8th. He was again admitted on 10th April, 1856; and remained till 30th October. His appearance had undergone no change, the leg measured thirty inches. He spent the year 1857 wandering over the country as a mendicant, and again returned to the hospital on 10th May, 1858, and remained to 12th August. At this time he was suffer-

ing from severe and protracted diarrhoea. The leg now measured thirty-four inches; the other appearances had undergone no change. He was much weaker than formerly. He was admitted again, for the fourth and last time, in a state of extreme debility and prostration, on the 4th January, 1859. The leg measured thirty-five inches, and he was labouring under very severe diarrhoea, which baffled all treatment, and continued till 19th June, when he died exhausted. On the day of his death the leg measured twenty-seven inches.

The result of the *post-mortem* examination was anything but satisfactory. The drawings before the Society accurately represent the external appearance of the body, except that the integuments were of a darker colour. There was a total absence of fat and cellular tissue, and the greatly-thinned integuments were everywhere adherent to the muscles underneath, which were wasted and of a pale greenish colour. The tumour could be easily dissected off and had no subcutaneous attachments. The brain was softer than in health, but presented no other morbid appearance. The heart was softened in its muscular structure. Right lung healthy. Left atrophied, adherent to the spine, carnified, and about the size of a turkey's egg. Liver, kidneys, and spleen healthy. The peritoneum and mesentery presented no morbid appearance, but the internal surface of the intestines was thickly studded over with small tumours resembling those on the skin. A slice of the leg and one of the cutaneous tumours were microscopically examined by Mr. M. Collis, of Dublin, and pronounced to belong to a class of tumours denominated "dermoid," non-malignant, "and having a great tendency to multiplication in the same subject." A slice was also sent to Dr. Cuming, but was decomposed before it could be examined.

I had hoped to have exhibited the leg for the inspection of the Society, but notwithstanding the greatest care, it became rotten and offensive, and the only portion that remained at all capable of examination was forwarded to Dr. Wales on the 28th inst., to be laid on the table.

{Rough minute book: Mr. Browne dissented from the term elephantiasis.

Dr. M'Gee said that it was not elephantiasis from its multiplication.

Dr. Ferguson said that he considered it disease of the skin.

Ordered to write to Dr. Babington regarding copies of drawings. Moved by Mr. Browne seconded by Dr. M'Minn.

Dr. Corry requests to take photographs.}

Case of Hypertrophy of Clitoris and Nymphæ.

By Surgeon Browne, R.N.

The plaster casts upon the table illustrate the appearance of the morbid parts before removal, and the

condition after. The first shews the size and position of the flap-like appendage, as it lay in front of, and concealing the vulva; the second shews the growth raised up, and displays the right nymphæ greatly enlarged; the left not so much so; while the third exhibits the appearance of the parts after the removal of the growth, and healing had taken place.

As will be seen, the hypertrophied structure measured 5½ inches in length, 3 in breadth, and was 7 inches in circumference at its largest point. The patient from whom these casts were taken, and this structure removed, had been for some years a prostitute, though she is now only in her 19th year. She states, that at the age of 13, she first had connexion, and suffered injury: from that time, however, she continued for some three or four years to earn her bread by prostitution; she then became diseased; after being cured, she went to the country for one or two years. About three years since, she observed the commencement of the growth which has since enlarged so much, and for several months she has not been able to pursue her unhappy calling, in consequence of the position the diseased structure occupied.

When she came into the hospital, I was not aware of the nature of the case; but desiring to ascertain her disease, I instituted an examination, and found the condition of things presented by No. 1 cast. Shortly after her admission, I determined to remove the impediment of which she complained. Having brought her fully under the influence of chloroform, I introduced a female catheter into the bladder, so as to mark the position of the orifice of the urethra, that I might avoid injury to that passage; I then made an incision on each side of the neck of the tumour, uniting them above, just within the *labiæ majores*, and then completely dissected off the hypertrophied mass, including the clitoris and nymphæ. There was very little hæmorrhage,—two small vessels only requiring ligation.

The upper part of the elevated structure, above the vestibule, for about one inch, was united by two sutures—the parts healed up satisfactorily, and left the improved face on affairs that are exhibited by cast No. 3.

After the external parts had healed, I examined, with the speculum, and discovered several growths on the walls of the vagina,—some attached by small pedicles, and two by broad bases, the largest being immediately below the orifice of the urethra. These I removed by means of the strong curved scissors. Some of these growths were of hard firm structure, covered by the fine polished mucous membrane; and others were of the soft friable character often presented by condylomata.

On examining the structure removed, it was found to consist of mucous membrane thickened, the mucous follicles being greatly enlarged, and the sub-

mucous cellular tissue filled with the so-called lactaceous deposit, similar to what is observed in cases of lipoma.

Amputation of Foot

Dr. MOORE exhibited a portion of foot, removed by Chopart's operation, on account of ulceration and swelling of a malignant character, at metatarsal joint of great toe, involving the next two toes and adjacent textures. There was considerable redness and tumefaction of the part, accompanied by pain. Dr. Moore was inclined, at first sight, to regard it as a specific ulceration, and it had been so looked upon and treated by the medical gentleman who consulted him in the case. The disease was progressing rapidly, and, fearing that it might extend to the ankle joint, Dr. Moore deemed its removal advisable, knowing as he did that several members of the young man's family (cousins) had suffered, and still are suffering, from malignant disease affecting different parts. One, a young gentleman on his return from abroad, consulted Sir Benjamin Brodie and other eminent members of the profession in London, for disease of the antrum, which had rapidly increased. He came to Dr. Moore with regard to operation for its removal; but from the extent to which the disease had engaged the bones of the face, and the ethmoid, and from its pressure on the eyeball, Dr. M. considered that there was not the slightest room for operative interference. From that time the destruction of the bones of the face, forehead, and lower jaw had progressed with great rapidity, laying open the cavity of the mouth, the orbit, and attacking the root of the tongue, rendering deglutition almost impossible. Another cousin suffered from malignant disease of breast, which was removed, but ultimately attacked her again with a fatal result. Another had a tumour of the neck of a large size, which was of a fibrous character, containing cysts of cheesy matter, which was removed by operation. Dr. Moore has since seen another member of the family with ulceration of the dorsum of foot, on which he looks with suspicion.

Council Council Meeting November [16?] 1859.

Present, Surgeon Browne, Dr. Drennan, Dr. Halliday, Surgeon Johnston, & Dr. Wales.

The circular was prepared as follows. For ballot for membership Barnwell White M.D. Edin. F. & L.R.C.S.I. Londonderry.

Surgeon Johnston will introduce a case of popliteal aneurism.

Surgeon Browne R.N. will exhibit a melanotic tumour, and will give details of the case and operation.

Dr. C. D. Purdon will read a case of aggravated hysteria.

THIRD MEETING.

November 12th, 1859.

Surgeon Browne, ex-President, in the chair.

{Rough minute book: Mr. Browne in the chair, Drs. Ferguson, M'Gee, Corry, Dunlop, O'Hare, Halliday, Arnold, Wales, Dill, Mulholland, M'Laughlin, Murney, Johnston, Thomson, M'Cleery, Smith, Bryce, Heeney, M'Minn, Ross.

Dr. Cuming proposed, Dr. M'Laughlin seconded, Barnwell White.

Drs. Hunter, Connor, Buckingham were elected.

Dr. Purdon's paper was postponed.}

Turning in Labour When the Pelvis is Contracted.

Dr. DILL read the following paper:—The question of turning in the case of a narrow pelvis, or in one very slightly contracted or deformed, must be considered by the obstetric practitioner as one of some importance. It is my intention to advance a few statements and illustrations, which will prove the impropriety of having recourse to this operation. At the same time, I may here state, that I shall not by any means assert that we may not have exceptional cases. My position is, that, as a general rule, turning, under such circumstances, is bad practice. It is Professor Simpson who to a certain extent revived, and now advocates, the affirmative side of the question; and, although his name and his authority stand high, yet, I believe, the weight of argument and evidence is against him.

The following are, very briefly, a few of my reasons for not turning, where the vertex presents, in a slightly contracted pelvis. And, first, have we not all very frequently observed cases of lingering labour, where the impaction of the head in the pelvis was such as to force us, for a time, to entertain the opinion that nothing but artificial means could dislodge it, but which has been expelled after all, by the natural efforts of the mother, thereby proving that while there is in many cases a contracted pelvis, or a want of relative proportion between the head of the child and the pelvis of the mother, nature unaided will overcome the difficulty, by our merely exercising a due amount of patience. Second. In my opinion the vertex is a more favourable part to present to the brim and outlet of the pelvis than that portion of the head which reaches the brim first when extracted by the lower extremities. In the first instance, you have a part presenting of a cone-shape, and by means of the sutures, the bones so overlapping, accommodating, and adapting themselves to the pelvis as to enable the head to pass through, though it maybe with difficulty; while, in the second instance, you have to deal with a firm, angular, unyielding body. I would, therefore, be disposed to ask, if the head, with a vertex presentation, will not pass through a slightly-contracted pelvis by the natural efforts, or even assisted by the forceps,

will the delivery not be more difficult, when the head is being extracted, after turning? Third. It will, I believe, be conceded that there is, at all times, considerable danger to both the life of mother and child in turning; and how often, even when turned, is it necessary to call in the aid of either the forceps or perforator to complete the delivery? But, even though these instruments be not required, have we not to contend with the long delay of the head all this time pressing upon the funis? Besides, is not the force which we are frequently obliged to apply to the neck in extracting the head, calculated not alone to endanger the life of the child, but seriously injure the soft parts of the mother? I was called upon to assist Surgeon S., in the case of Mrs. A. It proved to be very tedious labour, from a slightly-contracted pelvis in the conjugate diameter. The head had somewhat descended, but, from the long delay, it was thought right first to try the forceps, and, not succeeding, craniotomy was performed, and the child easily extracted by the hook. She became pregnant a second and a third time with similar results. I was sent for to attend the same woman in a fourth confinement, but on this occasion the breech presented, at which I was pleased, as it, without the risk of turning, afforded a favourable opportunity of testing Simpson's mode of dealing with such cases. The breech, trunk, and shoulders were expelled with some little assistance, but, with all my efforts, the head could not be brought away until it was perforated, reduced in size, and extracted by means of the hook; thus proving that by turning, in such cases, the practice becomes complicated, by adding a second, and it may be a third operation to the first.

{Rough minute book: Dr. M'Gee, Dr. Halliday, Dr. Heeney said that when the head was impacted we should not turn, but when the head is above the pelvis if the head can pass he would turn and by no means perforate.

Dr. Dill said that when the head could be brought away by turning it could be brought away by the long or short forceps.}

Surgeon BROWNE introduced a patient from whom the eye had been extracted in consequence of melanosis, and said that he would lay before the Society an account of the case at a subsequent meeting.

Dr. BRYCE introduced a patient, aged thirty-eight, affected with what were believed to be fibro-cartilaginous tumours of the fore-head of ten years' standing.

*Case of Horny Growth Removed
From Lower Lip.*

Surgeon BROWNE exhibited a horny growth which had been removed from the lip of a man 60 years of age in

the Cookstown workhouse by Dr. D. Hamilton, and which had been sent to the Pathological Society by Dr. Thomas Hamilton, late of Belfast. This, when recent, was an inch and a-half in length, being fully an inch in circumference at the point of attachment to the lip. The man had been a great smoker, but it seems that he had always held the pipe in the opposite side of his mouth. The part from which the growth had been excised healed up, and no return took place. Mr. Browne remarked that the Society had had three different kinds of necrosed structure before it, wherein dame nature's supply of material was more abundant than either ornamental or useful.

FOURTH MEETING.

November 18th [sic], 1859.

The President in the Chair.

{Rough minute book: President, in the chair, Dr. Halliday, Ferguson, S. Reid, M'Gee, Rea, Thomson, C. D. Purdon, Mulholland, Murney, M'Cleery, Browne, Patterson, Dill, M'Minn, Warwick, Heeney, Bryce, Johnston, Gordon, Wales, Murray, Moore, Arnold, Ross, M'Cormac, Pirrie.}

Case of Aneurism of Aorta.

The PRESIDENT gave an account of three of the cases of aneurism, the histories of which he had brought before the Society towards the close of last session,¹ and exhibited the heart and aneurismal tumour of the second of those cases.²

Case of Staphyloraphy.

Surgeon BROWNE introduced a young woman, aged 28 years, on whom he had operated for the case of cleft palate, on the 11th of last October. The part had united perfectly, the sutures having been removed on the fourth day of the operation.

He referred to a case he had published in the *Dublin Quarterly Journal of Medical Science*, 25th vol.³ and stated, that since that report, he had operated in four additional cases of cleft palate. In three of his cases, the operation had been completely successful; in one, partially so; and in another, failure followed two operations to which the patient had submitted.

He expressed his intention of giving his views on the subject of staphyloraphy, at some length, in an early number of the *Dublin Quarterly Journal*.

Artificial Anus.

Dr. MOORE introduced a patient who had consulted him with regard to the propriety of closing an arti-

ficial anus in his lumbar region. He was a soldier at the siege of Lucknow, and when in the act of holding his musket to his shoulder, received a gunshot wound in his left arm, close to the elbow-joint; the ball passed through the arm from without inwards, then entered the abdomen immediately below the lowest rib, and made its exit above the ilium, close to the spine. He was confined in hospital in India for three months, and afterwards transferred to one of the depot hospitals in England, being in hospital eight months in all. There is a slight discharge from the wound of matter, occasionally flatus, and several times during the twenty-four hours feculent matter passes through the orifice. Dr. Moore did not deem it advisable under the circumstances, to interfere.

Removal of Metatarsal Bone.

Dr. MOORE exhibited the diseased metatarsal bone of the great toe, which he had removed from a lad 15 years of age. There was considerable swelling, and three fistulous openings existed which communicated with the bone. The great toe and the rest of the foot were in a healthy condition. Dr. M. was anxious to try, by the removal of this bone, whether the symmetry of the foot could be preserved, and whether the great toe could obtain any support after the removal of its natural one.

Exostosis of Finger.

Dr. MOORE exhibited a little finger which was a marked example of exostosis of the little finger; the finger weighing upwards of three ounces. The lad's occupation was that of a weaver, and the disease interfered with his prosecution of it. It was removed at the joint, and the head of the metacarpal bone, which was quite healthy, was snapped off merely to preserve the symmetry of the hand.

In answer to a question from Dr. Heeney, Dr. Moore stated that the little finger of the other hand was slightly affected with the same disease. He had observed in such cases that some of the other fingers, and sometimes toes, were similarly altered in structure.

{Rough minute book: Dr. Gordon considered that it was a cartilaginous tumour and that exostosis was a misnomer.}

Case of Aggravated Hysteria.

Dr. C. D. PURDON read the following case—

A. B., aged 14, born in one of the Southern states of North America, of a nervous temperament, was attacked with intermittent neuralgia of the face, which continued for three weeks. After an interval of several days, gastric fever came on, and continued for six weeks. During the attack, the heart was feeble, and the pulsations amounted to 50 in the minute; and this slow state of the pulse continued for several weeks.

¹ [See page 786.]

² [Account omitted as it is identical to that given in the Post-script on page 793 which was taken from the Transactions.]

³ [*Dublin Quarterly Journal of Medical Science*, 1852, v13, p214. The case had been presented to the Belfast Medical Society on 1 September 1851 (see page 111 et seq).]

During the convalescence, she complained of a slight pain in the lumbar region, which lasted for a short time, and was at first attributed to exhaustion. This uneasy sensation remained for some days, and then became more severe at a certain period of the day, and after continuing some time, subsided—recurring again daily at the same hour. She complained now of intolerance of light. After ten days or so, on the subsiding of the lumbar pain, she was seized with a severe pain in the head, and great intolerance of sound; and now, each day, at the same hour, she was attacked with a very severe pain in the loins for about three-quarters of an hour; and on its subsiding, the head-ache came on, and lasted for an hour, when the paroxysm ceased. This attack came on day after day, increasing in violence and inducing great agony; and when at its height, she would throw herself about the bed in extreme pain, uttering frantic screams for four hours; on the attack subsiding, sleep would come on, and would last for a considerable time. As the disease progressed, delirium, and a state approaching to catalepsy, frequently came on, and lasted for some hours, also frontal neuralgia. The spine, at this time, became very tender, particularly at the lower lumbar vertebræ, the mammæ developed, and the uterus tender on pressure; and it appeared that the catamenia would soon appear, which, however, did not take place. The disease continued increasing in violence, the patient became more exhausted each day, and every remedy that could be thought of was used in vain, as well as moral control. She was now unable to use any exertion, and on account of the extreme agony she suffered in her back, she could not be raised, for when forced to sit up, an attack of hysteria was produced, and often followed by a cataleptic seizure.

It now occurred to me to try the effect of ice, which was used successfully by Sir H. Marsh in a case of hysteric vomiting; so, half-an-hour before the paroxysm came on, I applied it to the lumbar region, and kept up the application for four hours with the best result, as there was no attack that day. This treatment was followed for several days, during which time the threatened attacks became less and less, and after the withdrawal there was no recurrence of the paroxysm. Salt water was now poured over the back every day, and a wet bandage applied round the loins, with the best effect.

The intolerance of light and sound were greatly abated. After waiting for some weeks, she was raised in the bed, but the pain was so great that she became quite cataleptic for some time; after using strong sedative linaments to the spine for some time, it was again attempted to raise her, at the same time supporting the back, and still there was no improvement. I then made a gutta percha cast of the back, and padded it with cotton wadding, and applied it to the

back as she lay on the bed, and then raised her up a little without much inconvenience or suffering. Each day she was raised more and more, till she was able to sit upright. The catamenia now appeared very scantily, with a still further improval of the symptoms; and, although now and then she had frequent attacks of hysteria, in different forms, she still improved, and was soon able to be wheeled out in a Bath chair. After using the gutta percha cast for six months, she was able to take it off, and in a short time she could sit up in a chair without any other support than the back of it; and, after persevering for more than two years, I had the pleasure of seeing my efforts crowned with success, and the sufferer restored to health.

{Rough minute book: Dr. Purdon said that the ovary was the starting point.

Dr. Heeney asked was the globus hystericus present.

Professor Gordon thought we should take a broader view of the case and look upon the affection as part of a marked change in the system.

Dr. Pirrie knows that the case is hysteria of the mucous membranes of the intestinal case having been admitted as paralysis, then having a tumour of the frontal brain.}

Council Council Meeting November 23rd 1859.

Present, the President, Surgeon Browne, Drs. Dill, Heeney, & Wales.

For election William Greenfield M.D. (QUI).

Surgeon Browne will exhibit a melanotic tumour which had occupied the orbit, and will give details of the case and operation.

Dr. Heeney will read notes of a protracted case of prurigo resisting ordinary treatment.

FIFTH MEETING.

November 26th, 1859.

The President in the Chair.

{Rough minute book: Dr. Wales, Mr. Browne, Dr. Ferguson, Mulholland, Halliday, Patterson, Murney, Dunlop, H. Thompson (Ballylesson), Rea, M'Gee, Connor, Bryce, Johnston.

Dr. Greenfield of Holywood was elected.}

The PRESIDENT exhibited uterus and uterine appendages removed from a patient who had died in the Union Hospital. A large cyst existed, supposed to be connected with the round ligament of the uterus.

The specimen was referred to Dr. Murney for examination and report.

Surgeon BROWNE introduced a patient from whom he had removed three toes for serpiginous ulcer.

Dr. HEENEY introduced a young man, a millworker, in whom the left lung presented the physical signs of phthisis and extensive pleuritic effusion. He believed that succussion could be produced in the patient.

The patient was examined by several members, and a discussion ensued, in which there was evidenced difference of opinion with regard to the existence of the phenomenon in question.

{Rough minute book: Dr. Murney said that he would bring the association before the Society at next meeting.

Dr. Ferguson said that it might be water and flatus in the stomach. He thought that there was phthisis with effusion.

Dr. M'Gee said that there is no pneumothorax.}

Case of Melanosis of the Eye.

Surgeon BROWNE, R.N., read the following:—In *The Dublin Quarterly Journal of Medical Science*, for 1857, will be found a paper which I published on melanosis attacking the eye, and which was read before the Belfast Medical Society.¹ In that paper, I stated, in reference to the disease under consideration, that there cannot be a question that melanosis is closely allied, in some respects, to tubercular and cancerous deposits or growths, bearing some resemblance to both; like tubercle, it has not any true organization within itself, while the cancerous growths have; but, like all of these affections, the deposit of which it consists, once commenced, goes on to invade and destroy the organization with which it is in contact, finally leaving an inorganic or foreign mass in place of the vital structure which it caused to disappear. The origin and cause of melanosis we do not know; there is no appreciable sign by which such a development can be prognosticated, nor do we really know what is the first step in a disease which always leads to a fatal deterioration of the frame; hence, in this, as in all the so-called malignant affections, we cannot adopt any means to prevent their origin and consequent growth. Whether the system be in the first instance affected in all or in any of these malignant diseases, is very uncertain; but it must be admitted that a very short time elapses until it participates in the morbid action; and then the disease, no matter under what name, is no longer a local malady and removable. The question then arises, is there any time in the existence of these malignant affections that they can be said to be certainly removable? My belief is, that many of them may be so removed, when in the very early or the *inactive* stage, and are situated in parts that admit of operation. I believe that some of these growths may be removed with certainty before the taint has been reabsorbed into the system, and hence we have permanent recoveries after the excision of undoubted

cancerous or analogous growths. Now, I consider that melanosis of the eye illustrates this position. Very early removal of the eye has frequently preserved the system from contamination, and consequently has saved life, while late extirpation has always been followed by an outbreak of the disease in several other localities. Hence, I feel satisfied that whenever we find an eye deprived of sight, and presenting the signs of melanosis, we should extirpate at once; and the same remarks apply to cancerous and medullary disease of the eye. Melanosis usually begins within the eye, seemingly in the choroid; it is said also to attack the conjunctiva. I have never seen the disease, in the first instance, in that tissue; but wherever situated it soon invades the surrounding structures. Like the other forms of malignant disease, it is often associated with another form of destructive growth; and the case I am now to submit to the Society illustrates this fact, as will be seen presently.

On the last day of meeting, I introduced to your notice a respectable female whose eye I had recently extirpated in consequence of the organ being affected with melanosis; and the members had an opportunity of observing that the person seemed to be in robust health, as she stated herself to be. Her history may be briefly related. She is 66 years of age, is unmarried, had enjoyed good health till within the last two years. About fifteen years since, after exposure to cold and wet, she had severe inflammation of the right eye, which resulted in destruction of sight, but without deformity of the organ. Some time after, a small black speck become visible on the upper and outer side of the sclerotica: this gradually spread until the entire globe became involved in the disease. She never suffered any pain in the part until two years since. When I first saw her in July last, the globe was greatly enlarged and protruding—the camera was clear in its surface, but surrounded with a nodulated black mass, and behind it there was the same dark-coloured appearance. The eye was also quite immovable; while on its outer side, within the margin of the orbit, and in the situation of the lachrymal gland, there was a small hard mass, which could be slightly moved.

I advised immediate extirpation of the diseased structure, as the only chance for prolonging life. At this time, I should remark, the patient's health was very much impaired; she seemed weak and emaciated, she had lost her appetite, and her nights were nearly all sleepless, and she suffered constant severe pain; her colour was very dusky, and characteristic of a person labouring under malignant disease.

The first week in August I extirpated the eye—the patient being under the influence of chloroform,—the hæmorrhage was not very great, and was easily suppressed; the entire contents of the orbit were removed, with the exception of some perfectly healthy adipose structure. The optic nerve was divided close

¹ [See page 184.]

to the optic foramen. With the exception of some slight sickness at stomach,—the effect of the chloroform,—the patient recovered without an unpleasant symptom, and she returned home at the end of three weeks, greatly improved in health and in capital spirits, so that she could at last sleep, and eat, and drink, and enjoy life as formerly. More than three months have now elapsed since the operation, during which time the patient has not had a single uneasy sensation, and her health continues to be excellent; but time alone can shew whether the disease has been not only locally removed, but also completely banished. Of course the chances are rather against her, and in favour of a return of the disease, as there cannot be a question but that the taint of the disease was in the system before its local extirpation. An earlier operation would have given her a much better chance of complete immunity. This has been fully exemplified by the case to which I referred at the opening of this paper. That young lady now enjoys most perfect health, though more than two years have elapsed since I removed her eye. In her case, moreover, the system was still free from any apparent taint at the time of the operation. At all events, in the case immediately before us, the complete extirpation of the eye was the only chance to prolong the poor patient's existence.

The diseased mass removed is now before the Society, and presents the usual appearance exhibited by melanosis of the eye of some standing—namely, a complete destruction of the normal parts, and the substitution of this peculiar deposit. In its present state, after being in spirits for three months, it looks like a mass of fresh consolidated peat; the sclerótica and cornea alone remain, the former surrounded by the melanotic matter externally, and its inside completely filled with the same. When the parts were freshly removed, nothing of the original tissues, save those I have named, remained; the deposit seems to have filled up the inside of the globe of the eye, and then to have burst through the sclerótica on the upper and outer side, a line or two from the margin of the cornea. The growth seems to have been circumscribed or restrained, in a measure, by the suspensory ligament of the eye—the fibrous membrane, which Mr. O'Ferrall has described as the *tunica vaginalis oculi*—and which surrounded the growth like a capsule. This may be still observed, giving a smoothness to the surface of the growth. On the outer side of the removed mass, the hard substance to which I have already alluded was found loosely attached. This was not the lachrymal gland, but a scirrhous deposit, and which, under the microscope, exhibited the usually-observed cancer cells, thus illustrating what has often been remarked by pathologists, the coexistence of what has been considered distinct varieties of the carcinomata.

On examining the cut optic nerve, its structure was found to be quite healthy, and it had been divided beyond or outside of the capsule-like tissue, which surrounded and enclosed the melanotic mass.

I have already referred to the adipose condition of the orbit; this was perfectly healthy, and unaltered. The lachrymal gland, which was removed, was free from any change, though it was somewhat flattened by the pressure to which it had been subjected by the diseased growth.

Council Council Meeting November 30th.
Present, Drs. Browne, Read, Halliday, and Wales.
The circular prepared.

SIXTH MEETING.
December 3rd, 1859.
The President in the Chair.

{Rough minute book: Dr. M'Gee, Mulholland, Stewart, Patterson, Ferguson, Gordon, Warwick, M'Minn, Dill, Wales.}

Notes on Scarlatina.

Dr. M'GEE read the following:—

Scarlatina, from its prevalence and severity of late, having become of more than usual interest to us all, to bring the question fully before the Society, I have availed myself of its occurrence in a family which I attend, and where it was ushered in, accompanied, and followed by an epidemic, if not a contagious, visitation of a throat affection, closely resembling cynanche tonsillaris, attacking nearly all those of the family who had in former years had scarlatina.

The family in question, residing in a large, airy mansion, in a rural district, where scarlatina of a malignant type had appeared about three weeks before, consisted of fourteen, exclusive of servants, viz., the parents, governess, and eleven children. The five youngest children alone had never had scarlatina. Of the six elder children, five of whom had, in former years, passed through the disease, the youngest, a boy, Master F_, now aged 12, had had the disease (if at all) in so mild a form that a subsequent attack was prognosed.

This boy was attacked on the 14th Nov. by sore throat and difficulty of swallowing, accompanied by high fever, hot but moist skin; tongue thickly loaded with brown fur; no fiery edges on tip; no prominent papillæ. Both tonsils, the uvula and soft palate, were swollen and of a dusky red, and the lining membrane of the posterior nares seemed to partake of the inflammatory action. Notwithstanding the local application of nitrate of silver, and the use of antiphlogistic treatment, the left tonsil and left side of the soft

palate suppurated and burst on the fifth day, when the fever subsided, leaving a cool, but harsh, dry skin. The uvula now became rigid and more swollen, as if infiltrated, and its point covered by a diphtheritic patch, stood prominently forward. On the tenth day his pulse had fallen to 68, and his pupils, usually large, were still more dilated. He had no rash nor desquamation, and his tongue, on becoming clean, shewed no trace of scarlatina. On the 12th day he was convalescent, and recovered without further unpleasant symptoms.

On the 19th Nov., five days from Master F_ being attacked, one of the younger children sickened—the tongue and throat indicating scarlatina, and a well-marked rash appeared on the third day. Between the 19th and 22nd, the remaining four of the younger children were attacked by scarlatina. Of the five cases, three might be termed scarlatina simplex, and two scarlatina anginosa. In all, the characteristic strawberry tongue was present. The tongue covered over its roots and centre by a thick, brown fur. On this coating becoming detached (about the fourth or fifth day), had the raw-beef appearance, with a glazed centre, as if seared by a hot iron. All, during the progress of the disease, had the uvula swollen, rigid, and protruded, or pointed forward, as in the case of Master F_, and in two there were a few small patches of diphtheria on the tonsils. They were all convalescent on the tenth day. During convalescence, three shewed some slight puffiness of the face. In two, the desquamation was furfuraceous, and in three flaky.

I need not at present occupy the time of the Society with a detail of the local and general treatment. I may state, however, that so long as there was morbidly pungent heat, I used frequent tepid sponging, and gave nauseating doses of ant. tart., without any evidence of sinking. To the tonsils, uvula, and soft palate, nitrate of silver, in both its solid and fluid state, was applied freely during the first three days of the attack.

During the progress of the younger children toward convalescence, three of the elder children, with the governess, and Mrs. F_, were attacked by sore throat, with much pyrexia and constitutional disturbances; pulse very quick; skin hot, but moist: tongue furred deeply; dark brown at the root and centre; loss of appetite; little thirst. In every one of these cases diphtheritic patches were observable on the tonsils and uvula—very trifling, indeed, in three of the cases, and well marked in two. Mild purgatives when required, stimulants to the throat externally, and nitrate of silver internally, were the remedial measures adopted in four of these last cases, and I tried a capsicum gargle, but it did not answer. I am happy to be able to say that the four here referred to are convalescent, the tongue having presented nothing of the raw, seared look present in the cases of scarlatina.

I have now to describe the remaining case, that of Miss F_, aged 21. She was seized with symptoms closely resembling those of Master F_, my first patient, but in a more intensified form, with some pain on pressing over the thyroid cartilage and sides of the trachea; no hoarseness, and little pain in speaking; deglutition difficult, and very painful; the left tonsil and left side of the soft palate more especially affected. The uvula on the second day became rigid, and as if infiltrated. Treatment similar to that adopted in Master F_'s case was used, with the inhalation of the vapour of hot water and vinegar, with external stimulants. On the sixth day, the left tonsil had suppurated and burst; but, although the fever abated, and the pulse fell to 86, she had little relief from pain. Swallowing still difficult and painful; both tonsils tumid; uvula yet more rigid, and turned upward and forward, shewing its posterior surface, with its rounded tip, as if adherent to the soft palate anteriorly. The uvula, both tonsils, the arches of the soft palate, were covered by a diphtheritic exudation, of which some patches were observable on the pharynx. As is observable in some cases of cynanche tonsillarum, there was difficulty and pain felt in opening the mouth. The parts affected were mopped over with a solution of chloride of calcium, of a strength varying from two to four parts of water to one of the ordinary solution. This I have found to be a valuable application in foul or sloughing throat, or mouth affections; but it requires to be applied by means of a mop made of linen, as it almost immediately destroys sponge. Under this treatment Miss F_ is convalescing, though slowly. The diphtheritic exudation is gradually clearing off, and no fresh patches have shewn themselves, excepting some very trifling ones on the gums over the front teeth in both upper and lower jaws.¹ As I do not remember to have seen any case recorded in which the peculiar affection of the uvula is described, I request my medical brethren will give me the result of their experience thereon.

Some questions of interest present themselves in regard to these two sets of cases. Were the cases of scarlatina and those of throat affection the same disease? Where should we seek, if we search at all, for the source? Is it probable that the poison was conveyed to his home by the father, nine days before the outbreak in his own family, having been in contact with a mild case of scarlatina at a distance of eighty or ninety miles from home? Should we refer the source of the contagion to the immediate neighbourhood where scarlatina was rife, or to some atmospheric

¹ Dec. 31.—Miss F_ has had a return of the inflammation and swelling in the left soft palate, which rapidly spread across to the right side. Tongue deeply furred, of a dark brown colour; much difficulty of swallowing. The swelling and pain continued unrelieved, until recourse was had to free scarification of the soft palate, when she convalesced rapidly, and is now quite well—Note by Dr. M'Gee.

condition? I should not omit to state, that the servants escaped an attack, though not more favourably situated, and though two of them were in close and constant communication with the sick.

In reply to Professor Gordon, Dr. M'GEE referred to the difference in the appearance of the tongue in the two sets of cases. In all the scarlatina cases the strawberry tongue was present, succeeded by a clean, seared or glazed centre, varying in intensity in the patients. In the other cases, the tongue was covered by a thick coating of brown fur. As to the exudation being aphtha, Dr. M'G. observed that neither had the patches the appearance of aphtha, nor were his patients of the class or of the bodily condition in which such a disease could be expected to occur. As to the manner in which the poison of contagious disease had been conveyed, though he had but submitted the question for the consideration of the meeting, he detailed some curious instances.

To Dr. Ferguson, he replied that he viewed the rigid condition of the uvula as analogous to œdema, as it affects the epiglottis. He could not agree with Professor F. in classing all the cases under the head of scarlatina, even while admitting that scarlatina may appear, as he had seen it, twice in the same subject, and that the primary attack modifies or diminishes the severity of a second attack. He observed that, while the scarlatina rash is sometimes absent, yet it is usually in the very severe or malignant cases that the rash is absent. Now, in the two sets of cases there was a marked distinction:—in the tongue, as already described; in the skin, which was hot, but moist; in the throat affections, hot and dry, with a sense of itching in the scarlatina; and there was consequent desquamation in the latter cases, none in the former.

Surgeon JOHNSTON, who had entered the room after the reading of Dr. M'Gee's paper, detailed some complications attendant on cases of scarlatina in his practice, and he referred especially to diphtheritic exudation, and a very interesting discussion arose as to sthenic and asthenic cases, and as to the particular tissues affected in scarlatina.

Malignant Disease of Antrum.

Dr. MOORE introduced a patient, a man aged 57, with disease of antrum. About nine months ago he perceived a swelling in the cheek, and afterwards experienced pain in his gum, with loosening of a tooth. He consulted Surgeon Thomson, of Ballylesson, who diagnosed disease of the antrum, and advised him to come to Hospital for operation; but for weeks after this advice he did not present himself. On admission, it was found that the roof of the mouth had lost its resistance; there was swelling of the alveolar process, with slight discharge therefrom, and prominence of the upper maxilla. In this condition he was shown to the Society, but on Dr. Moore explaining to him the

nature of his case, and the operation which would be required, namely, to remove the whole of the superior maxilla, with the floor of the orbit, and the great risk of hemorrhage, he would not consent to the operation; nor did Dr. Moore, considering his time of life, urge or wish him to undergo it, but if the patient himself would urge it he would have no objection to undertake the task.¹

Council Council Meeting December 7th.

Present, Drs. Moore & Wales.

The circular prepared.

SEVENTH MEETING.

December 10th, 1859.

Dr. Murney, V.P., in the chair.

Removal of Tumour.

The SECRETARY exhibited a portion of a tumour forwarded by Dr. BABINGTON, V.P., Londonderry, and read the following communication from that gentleman:—

“I have forwarded for exhibition at meeting of Pathological Society, half of a tumour which I removed this morning at the Infirmary here. The patient was a healthy man, aged 42. The tumour was situated on the right scapula. Had been removed twice before; first time in this infirmary, eight years since; second time, five years since, by a practitioner in his own neighbourhood. The tumour again began to grow about a year since, and has attained its present size. On removal it weighed 1¼ lb. It had no deep attachments; was contained in a capsule; and was nourished by ten arteries. You will observe a patch of ulceration on the portion sent, from which he had frequent attacks of hæmorrhage.”

Case of Hare-Lip.

Surgeon BROWNE said—The little patient which I have the pleasure of exhibiting to the Pathological Society, is one I operated on for simple hare-lip on the 15th of October last, and in whose case I used a new sort of suture. Before I enter upon any description of the operation, I beg to call the attention of the Society to the splint and metallic suture I now hold in my hand. This is the splint that has been lately introduced to the notice of the profession of this country by Dr. Battey of America, and used by him for the cure of vesico-vaginal fistulas; and who, when here, in the month of October, kindly explained to me his operation for the lesion in question. I have not had any opportunity of using his splint and metallic sutures in a case of vesico-vaginal fistula, but at the time of his describing his method of approximating the fistulous

¹ Since then the disease has increased rapidly, the patient having left the Hospital.

edges, it struck me that the appliance could be adapted to a case of harelip. A very short time before this, I had operated upon a fine little fellow, three years old, the son of a gentleman in town, for hare-lip, using the ordinary needles and twisted sutures. The operation was quite successful; but I had so much difficulty in removing the needles, at the end of three days, and as one of them, which I had to leave in for another day, caused deep ulceration of the part, I determined to adopt a different method the first opportunity; and having seen Dr. Battey's splint and sutures, I fixed upon his appliance.

The child before the Society presented soon after. It was then six weeks old, a remarkably fine infant, but with a single hare-lip, the upper part of the fissure exhibiting the shape of the letter V, in consequence of a central part which stood out beneath the septum of the nose. Having the splint prepared, with three sutures attached, I brought the child under the influence of chloroform, rapidly pared the edges of the fissure, and then, with a long three-edged glover's needle, I carried the metallic sutures completely through the right and left sides of the lip, embracing both skin and mucous membrane, about the 16th of an inch from the raw edge. I then drew the sutures home to the splint, saw that the wounds were in close apposition, and fastened each point by taking a turn or two of the wire around and beneath the little shot in which the opposite end was made fast. At the end of three days I removed the splint and sutures very easily by dividing the latter as they lay across the former, then by gently raising the splint upon its edge, the sutures were drawn out without causing any disturbance or pain.

The part I found to have united, save at the top—the site of the V-shaped portion—where the splint had got in beneath its point. However, I applied three slips of court plaster, and did not disturb the parts for two more days. On the fifth day after the operation, and while endeavouring to fix the little V part in its place, the child screamed and struggled violently, and the consequence was, the newly united parts were torn asunder. Though not very well pleased, I was not much disconcerted by the *contre-temps*. I prepared a new splint, pared the edges afresh, and once more brought the parts into apposition. The sutures, as before, were removed at the end of three days, and, after carefully dressing the lip for some ten days, with ordinary adhesive plaster, complete and firm union was established.

So far as I can judge, this splint and these sutures will be found very useful in the surgical treatment of hare-lip. They bring the parts into, and retain them in, close apposition; they cannot strangulate any part of the lip; they are very easily removed; and they cause exceedingly little irritation, and might be left in for many days without causing ulceration.

The splint is a thin piece of lead, half an inch in breadth, and as long as may be required. It is perforated by small holes, at intervals of a third of an inch; these are in two rows, a fourth of an inch apart, and a small slit is carried from each hole of *one* row through the edge of the splint. The sutures are No. 32 wire, iron or silver, and each is passed through a small perforated shot, these shots forming the points of attachment for both portions of the suture. The only thing to be observed in the application of this apparatus is the accurate passing of each suture through the entire thickness of the lip, and that they are introduced at an exact distance from the cut margin.

Council Council Meeting December 14th.

Present, Professor Reid, Dr. Heeney, Dr. Halliday, Dr. Wales.

Circular prepared.

A/c of 19/- for postage and stationary ordered to be paid.

EIGHTH MEETING.

December 17th, 1859.

The President in the Chair.

{Rough minute book: Present, Drs. Halliday, Johnston, Stewart, Ferguson, Warwick, Johnston, Thomson, [John?] Moore, Gordon, Patterson, Rea, Heeney, Wales, Connor, Browne, Mulholland, Bryce, Dill, Murney, Moore, M'Cormac.}

Inversion of the Bladder.

Surgeon JOHNSTON read the following—

On the evening of Sunday, August 8th, I was requested to visit Mrs. M_, aged 20 years, and was informed that she was threatened with a miscarriage. On visiting her I found my patient apparently suffering very intensely from "pains," attended with such tenesmic efforts, as to induce her to remain almost constantly on the night-chair. I was told that there had been considerable hæmorrhage with discharge of "waters" the previous day. She had been nine months married, and calculated that she was rather more than four months pregnant. For weeks past she had suffered from irritability of the bladder, but enjoyed very fair health until Friday, the 6th, when, after over-exerting herself in lifting a box, she felt great uneasiness in her back, attended with frequent and urgent desire to pass water. These symptoms became more urgent on Saturday, and were accompanied with severe attacks of vomiting. She was unable to retain the contents of the bladder; the tenesmus was most distressing; and she had no relief except when on the night-chair. It was thus I found her on my first visit; and after considerable persuasion I succeeded in get-

ting her to retire to bed. On my attempting to make a vaginal examination, she became very impatient, and complained very much of the intense pain I gave her, far exceeding that commonly given in a vaginal examination. This did not escape my notice. On examining I found a soft fluctuating tumour, in size about that of a pear, pyriform in shape, extending as far down as the os externum of the vagina, and feeling very like a bag of membranes. My finger passed from the base of the tumour along its narrow neck-like portion, into a small narrow cavity, which I considered was the dilated os uteri, being also under the impression that the narrow neck-like portion of the tumour was the cord attached to the ovum. I followed up this cord into a cavity, which I presumed to be that of the uterus. My patient now insisted on being allowed again to remain on the night-chair, and complained of her inability to bear any further examination. Being under the impression that the uterus would expel its contents, and there being no hæmorrhage, I gave some general directions and returned home.

I visited her on Monday morning, and found her in the same state of suffering; and having slept none during the night, her pulse was now excited, and the attacks of vomiting frequent. She was unwilling that I should make any examination. I therefore administered an anodyne, and returned in the evening with my friend Dr. Bryce, to whom I communicated my impression that my patient was going to miscarry. He examined the tumour; but in making his examination, discovered that he could pass his finger up behind it, into the vaginal canal, where he felt the “os uteri” still undilated. He felt puzzled to explain matters, and at first suggested the idea that there was a malformation. On further consideration he concluded that the tumour was a vaginal vesicocele—a prolapsed bladder—and not a bag of membranes.

Dr. Bryce’s discovery of the vaginal canal, and of the os uteri still undilated, was certainly new light to me. I again made an examination of the tumour; in doing so, I found that it yielded to gentle pressure, continuing which, it retired upwards, through the cavity which I had supposed to be the os, into the cavity which I had supposed to be the uterus, but from which flowed a small quantity of urine. The true nature of the case was for the first time manifest, viz., that it was one of inversion of the bladder, that the os through which I passed the tumour was the “meatus urinarius,” dilated to such a capacity as to admit two of my fingers. I suggested this explanation to Dr. Bryce, and, in order to satisfy ourselves on this point, we made an ocular inspection of the state of the meatus urinarius, which confirmed the diagnosis. Immediate and decided relief followed the reposition of the inverted bladder; the vomiting ceased; the pulse fell; our patient’s expression changed; the pain in the back ceased; the urgent symptoms of irritation of the

bladder were almost quite relieved; and she soon fell asleep. We visited her some time afterwards, and found that there had been no return of the inversion. I drew off a quantity of bloody urine with the catheter. We enjoined her to employ no voluntary efforts in micturating, for a time; administered an anodyne; and ordered an oil draught the following morning.

The next day I found her comparatively easy. During the next month, however, she suffered from incontinence of urine, even when sleeping; and complained very much of a scalding sensation in the urethra. The urine was bloody, and there was a considerable deposit of mucus. These symptoms were treated, and gradually disappeared. I saw her last on the 3rd of December. She was then quite free from any vesical uneasiness; was able to retain her urine as usual; felt in perfect health; and was soon expecting her confinement.

Believing that medical science may be advanced by a publication of our mistakes, as well as of our successes, in practice, I have given a fair and candid account of this peculiar, and I believe I may add uncommon, case.

Prior to my meeting with it, I had never heard of such an accident. I was, therefore, quite unprepared for it, and did not recognise it. It is well that it should be recorded, in order that it may enable others to exercise caution in dealing with tumours of an obscure character, and attended with perplexing and anomalous symptoms. We should ever be prepared to meet with cases presenting symptoms and features for which we may have no precedent. It may appear strange that I was so slow in recognising the true nature of the case, and that in the first instance I made a very decided, and what might have been a very serious, error in diagnosis (as owing to the view I first took of this case I contemplated puncturing the membranes). I had been led to believe that Mrs. M_ was about to miscarry. My mind was preoccupied with that idea; and after I examined, I felt so satisfied that the tumour was the ovum entering and protruding from the os, that I did not see any necessity to push my external examination, and my patient was certainly very unwilling that I should do so. To Dr. Bryce belongs the credit of throwing that light on the case which led to the recognition of its true nature. I have been unable to discern any similar case on record, viz.—inversion of the bladder occurring during pregnancy.

Dr. Meig, in his work on “Diseases of Women,” details the history of a case of inversion of the bladder at the orifice of the urethra, in the person of a little girl three years of age. In her case, it was mistaken for a vascular tumour, and was about being ligatured, when its true nature was fortunately discovered. Dr. Murphy had a similar case in Dublin, an account of which I have been unable to find. Jones and Sieveking,

Belfast Clinical and Pathological Society
Seventh Session: 1859–1860
President James Seaton Reid

in their "Pathological Anatomy," mention the possibility of introversion of the bladder, and even, in females, of its projecting from the meatus urinarius externally. We find, therefore, that inversion of the bladder is an accident with which we should be prepared to meet in females—that we may meet it in children, or in pregnant females. In the former we should be careful to distinguish it from a vascular tumour, and avoid ligaturing it; in the latter from a bag of membranes, and avoid puncturing it, as in either case fatal results would be almost certain to follow. I would only suggest whether we might not mistake inversion of bladder for polypus?

{Rough minute book: Dr. Patterson saw with Dr. Simpson a case of prolapsus of the bladder.

Dr. Bryce said that he corroborated Mr. Johnston's remarks.

Dr. Gordon said that there must be malformation of the urethra and some deficiency of the neck of the bladder.}

Surgeon JOHNSTON also introduced a patient, the subject of extraordinary contraction of the thoracic parietes, the result of empyema.

Council Council Meeting January 4th 1860.
Present, President, Drs. Browne & Wales.
Circular prepared.

NINTH MEETING.

January 7th, 1860.

The President in the Chair.

Dr. HEENEY introduced a patient over the greater part of whose chest a loud blowing sound could be heard, the cause of which was the subject of considerable difference of opinion among the members present.

Pericarditis and Hypertrophy of Heart.

Dr. PIRRIE exhibited a greatly-enlarged heart, weighing 34½ oz. There were vegetations on the mitral and aortic valves. The pericardium was covered with highly-organized lymph. The patient had had an attack of rheumatism two years since, which had left him subject to palpitation, in consequence of the increasing hypertrophy. A recent attack of rheumatism caused his admission to Hospital, during the progress of which pericarditis had supervened.

Council Council Meeting January 11th 1860.
Present, the President, Drs. Dill, Murney, & Wales.
Circular prepared.

TENTH MEETING.

January 14th, 1860.

The President in the Chair.

{Rough minute book: Murney, Dr. Dill, Browne, Dunlop, Warwick, Heeney, Patterson, M'Cleery, Mulholland, M'Minn, Wales, Johnston, Stewart, Connor, Cuming.

Dr. Heeney introduced the question of the existence of gonorrhœal rheumatism, expressing his belief that there was no pathological connexion between gonorrhœa and rheumatism, and stating that he had not in an experience of several hundred cases of gonorrhœa met with rheumatism on more than two or three occasions.

Dr. Brown concurred with Dr. Heeney believing rheumatic attacks occurring during gonorrhœa to be merely coincidences.

Surgeons Warwick and Johnston differed with Dr. Heeney stating that they had both observed cases of gonorrhœa in which rheumatism had occurred in successive attacks of gonorrhœa in the same person.}

Some Cases of Excision of the Eye.

Mr. BROWNE read the following:—

In the Transactions of the Pathological Society for last session will be found the record of a case in which I excised the globe of the eye,¹ to relieve the patient from the constant pain which he suffered, and to save the other eye from the destructive effects of irritative or sympathetic inflammation with which it was threatened, and which is a most intractable form of disease, and very frequently destructive of vision.

I have now to bring before the Society two other cases in which I excised an eye, and for similar reasons, and under similar circumstances, to the one already related.

The first is that of A. M'G., aged 54 years, from Islandmagee. About eleven years ago, a chip of metal was driven forcibly into his right eye; the immediate consequence was intense inflammation of the organ, with great swelling; when this subsided, he was without any vision in the eye. From that time, he suffered at intervals excruciating pain in the part, and which, during the time, incapacitated him for any work; latterly, the left eye began to be affected with cloudiness of vision, and he was advised to have the injured eye removed.

In August last I excised the globe; he recovered without a single backset, and returned home at the end of a fortnight. Since then he has been quite free from his former severe suffering; he is in perfect health, and the left eye has quite recovered its impaired vision.

¹ [See page 785.]

As in the former case, a minute particle of metal was found imbedded in the choroid, near the bottom of the eye; and the lens, vitreous humours, and retina, had completely disappeared.

The second case is that of B. M'G., aged 46 years, of Belfast. Some seven years since, this man was struck upon the eye by a chip of metal, which stuck in the margin of the right cornea, but did not penetrate. Severe inflammation followed—this I was enabled to subdue by active treatment. For some time the sight did not seem to have suffered; but, at the end of several months, vision began gradually to be lost, without any severe pain. About that time, he received another blow in the eye from a chip of metal—this rekindled active inflammation, and vision became permanently extinguished. I was not certain whether this latter chip of metal had penetrated the chambers of the eye; but as he suffered very severe paroxysms of neuralgic pain in the globe and eyebrow occasionally, it was considered probable that a foreign body lay in the interior of the organ. About a year ago, the left eye became sympathetically affected, vision becoming cloudy and indistinct; this, with the frequent attacks of pain in the right eye, prevented him from following his trade, that of a “fitter,” and he finally consented to have the injured organ excised. This operation I performed early in September last, and with very good results, as the patient has been free from pain ever since, and the clouded state of vision in left eye is gradually clearing off.

I carefully examined the excised eye, but could not find any foreign body, properly so called; but the structure of the part was entirely changed. The choroid was thickened and strongly adherent to the sclerotic, while it surrounded and was firmly attached to bone-like lamina of considerable density, which represented the hyaloid membrane. There was not any vestige of the retina left, and the lens was shrunk to the size of a mustard seed. This, the nucleus, apparently, of the lens, was attached loosely to the hollow bony plate which had replaced the anterior part of the hyaloid membrane. The iris and ciliary body were thickened—the former adherent to the cornea. The long ciliary nerves were seen penetrating the sclerotic and passing along the surface of the choroid to their destination. On separating the choroid from around the optic nerve, the mouth of the central artery of the retina was visible, and the remains of its direct branch which runs in the vitreous humour to the back of the lens, could be seen entering a foramen in the posterior bony plate which represented the hyaloid membrane.

This conversion of some of the inner structures of the eye into bony or calcareous matter I have frequently seen. I had a beautiful specimen of a crystalline lens I extracted, which had been converted into a solid, polished bony ring, the centre consisting of a

very fine cribriform plate. But I have never before seen the vitreous humour, or rather the hyaloid membrane, thus changed into bone-like structure. The cases I have now submitted to the Society beautifully illustrate the several results which may follow inflammation in the same organ in separate individuals. In one, scarcely a vestige of normal structure remains; in another, a part of these structures are converted into a new organization; and in a third, an inorganic material has not only replaced the original structure, but has invaded the surrounding parts also; and beyond that, even the system has become contaminated from this source.

With respect to the operations of extirpation and excision of the eye, I need scarcely trouble the Society with any remarks, beyond stating that the one is very simple as compared with the other, as may be imagined, as in the one case the entire contents of the orbit are, or should be, cut out, while in the other, the globe is merely removed.

Council Council Meeting January 18th 1860.

Present, the President, Drs. Halliday, Johnston, Dill, Browne, & Wales.

Circular prepared.

ELEVENTH MEETING.

January 21st, 1860.

The President in the Chair.

{Rough minute book: Drs. Dill, Mulholland, Halliday, Bryce, Patterson, M'Minn, M'Gee, Heeney, Cuming, T. Reade, Warwick, Rea, Johnston, Wales, Moore, Murney.}

Retained Placenta.

Dr. HALLIDAY read the following case:—

On Saturday, the 16th inst., I was called upon, at 12 o'clock, noon, to visit Mrs. S., aged 38, a dispensary patient, who, I was informed, had been delivered prematurely of her twelfth child, at 6 A.M.; and the placenta not having been thrown off, the parties became uneasy. I found her in bed, free from pain, but evidently under the influence of drink; there was little or no loss. On making an examination, and exerting gentle traction on the cord, it broke off; the midwife having previously tried to remove it by pulling. I was barely permitted to pass my finger inside the vagina, up to the os uteri, which was considerably closed, but through which I could feel the edge of the placenta. Upon endeavouring to pass my hand a little further, so as to lay hold upon it (having previously firmly pressed over the fundus), she became exceedingly impatient, and would permit no farther interference. I endeavoured to reason with her, but all in vain. I then

prescribed ergot, and left. On calling again I found she had not taken the medicine, but said she would not mind anything, as she was well enough, and would be all right. For two or three days she remained free from pains, and had little or no discharge, when she got up and attended to her household duties. On the fifth day after delivery she began to have occasional loss, with pains, which increased up to Tuesday week, the eleventh day, when the mass was expelled, accompanied with violent hæmorrhage, occurring to such an extent as to endanger life. She recovered, however, although slowly; and months elapsed ere she regained her usual looks or health.

I should have stated, that during all the time there was little or no pain on pressure; the pulse was but slightly quickened; and the child, though it lived for a short time, could not be quite seven months.

{Rough minute book: Dr. M'Gee spoke with reference to the dispensary question. Dr. Halliday should have given in his patient to protect himself from possible consequences.

Dr. Dill thought that Dr. Halliday should have given chloroform and not have left the patient.

Dr. Murney exhibited morbid parts removed from a man who died in consequence of a fall down a staircase of a steam vessel.}

Penetration of Brain by a Nail.

Surgeon JOHNSTON read the following case:—

A lad aged 15 was, with other boys, amusing himself and them by firing off a pistol, to ram down the colfing of which they used an ordinary cut nail of about four inches in length, as a ramrod. The nail was slightly bent. Accidentally the pistol went off in the hands of one of them, while the nail acting as the ramrod had not been removed. In consequence of the discharge the nail passed through the hand of one of the lads, and entered the brow of the patient, above the internal angular process of the frontal bone, passing horizontally into the brain. He was seen by Surgeon Johnston and Dr. Bryce, who, on examination, found a hard body embedded underneath. The nail was then withdrawn by Mr. Johnston and the boy sent to Hospital.

Dr. MOORE stated, that when the boy was admitted to Hospital there was slight ptosis, with swelling of eyes. He ordered him to be put under a mercurial treatment combined with antimony. This course was pursued, due attention being paid to the state of his bowels, till ptyalism was produced, cold lotions being applied to the scalp, the hair having been shaved off. Under this treatment his pulse, which had risen to 120, gradually became slower. In a few days the exudation from the wound was of a clear amber-like colour, in considerable quantity, and which became gradually less as the wound cicatrized. Dr. Moore

remarked that he had seen many injuries of the brain from the wounds of which the same class of fluid exuded when the substance of the brain had been penetrated. Dr. Moore did not wish to bring him down from his ward, as his pulse rose on the slightest exertion or excitement, but hoped, on that day week, that he might be able to do so.

Dr. HALLIDAY introduced a boy the subject of very frequent micturition, each evacuation of the bladder being followed by a discharge of blood.

Council Council Meeting January 25th 1860.

Present, the President, Drs. Cuming, Halliday, Browne, & Wales.

Circular prepared.

TWELFTH MEETING.

January 28th, 1860.

The President in the Chair.

{Rough minute book: Present, Dr. M'Gee, Moore, Wales, Ferguson, Patterson, M'Cormac, Rea, O'Brien, Johnston, Moore, Cuming.}

Dr. WALES introduced a patient with an intractable eczema.

{Rough minute book: Dr. M'Gee uses chloride of lime alternating with stupes of bran water and using occasionally ... [?] applications [?].

Dr. Ferguson would treat him as antiphlogistically as if he had pneumonia.}

Injury of the Brain.

Dr. MOORE introduced the boy whose brain had been penetrated by a nail, and whose case had been described by Surgeon Johnston and himself at previous meeting. The lad was doing very well.

Tumour of Cranium.

Dr. MOORE introduced a patient with extensive atheromatous deposit, forming a continuous tumour of the forehead and side of the head, who had come to the Hospital expecting its removal by operation. From the nature of the tumour, and its extent, he did not think operative interference advisable, but merely introduced the patient as an example of an interesting affection.

Scirrhus of the Pylorus.

The PRESIDENT exhibited the liver, kidneys, heart, and stomach of a woman who had died in the Union Workhouse of scirrhus of the pylorus. He said—I exhibit to-day some morbid parts removed from the body of a married female aged 56, who died a few days ago in the Union hospital.

She complained on admission chiefly of cough, and some dyspnoea, and that she had suffered occasionally from vomiting. The chest symptoms were soon relieved by the ordinary treatment, when vomiting became a more prominent symptom, and led to an examination of the region of the stomach, where a knotty tumour was found rather to the left of the medial line of the epigastrium, and could be traced to be connected with a larger, but much smoother tumour in the right hypochondrium. There was, however, so distinct a sulcus to be felt between the two, that I considered there was evidence of scirrhus pylorus, as well as of enlarged liver. The vomiting was immediately checked by bismuth, lime water in milk, and a diet of bread and milk—a course of treatment which I have often found markedly beneficial in similar cases, only requiring small quantities to be administered at a time. The vomited matters had never been discoloured, or of “coffee-grounds” character, consisted chiefly of food, and an acid, glairy fluid.

The vomiting did not return for fourteen days, when it became for the first time of “coffee-grounds” character, and continued so until her death, accompanied by tarry evacuations from the bowels. These, no doubt, led to a fatal termination sooner than I anticipated, for she was neither so emaciated, nor had her abdomen the retracted appearance which almost invariably precedes death in such cases. This latter might, perhaps, be partly owing to the fact that she had never given birth to a child, and, consequently, the abdominal walls had not lost their natural tension, whilst the absence of extreme emaciation, was, no doubt, owing to the fact revealed by the post-mortem examination, that the pyloric orifice was patent enough to permit the digestive process to be generally completed. Like many childless women, she had a considerable beard upon the chin.

The post-mortem examination revealed a moderately dilated stomach, with a dark patch on the mucous membrane of the greater curvature, and a similar, but smaller, discolouration near the pyloric orifice; from these the blood had probably been effused, but there was no ulceration in either. The pyloric orifice was surrounded by a hard, but not very thick, ring of scirrhus matter, with nodulated parts on both the mucous and peritonæal surfaces. It admitted readily the passage of the little finger through it; and there was no ulceration. A firm adhesion existed between the pyloric end and the liver; and the sulcus observed during life was still quite evident.

The liver was greatly enlarged, and was studded with a large number of whitish-coloured tumours; some distinct, and having a well marked central depression, whilst in other parts they appeared to run into each other. Where some of these tumours were in contact with the peritoneum of the abdominal parieties, an elevated deposit had taken place on the

latter, but without any direct vascular continuity. Similar tumours also existed in the omentum, which was attached to the uterus by a firm adhesion.

A section of the liver found some of the tumours distinct, but the majority coalesced, and left little of the natural structure of the liver to be seen. A few of the tumours had a vascular ring about one-eighth of an inch from their circumference. Their density was not so great as the deposit at the pyloric orifice; but near the latter there was one that was so soft as to bear a great resemblance to broken down reddish cerebral matter.

The microscopic examination by Dr. CUMING confirmed the opinion that the deposit in the liver was that of encephaloid cancer. The spleen was free from disease.

Enlargement of Testicle.

Dr. MOORE introduced a patient who had been admitted to hospital with a chronic enlargement of testicle to the size of an ordinary clenched fist. He did not look upon it as a malignant disease, but as that class of enlargements of the testes which is remediable by the introduction into the bladder, twice or so weekly, of a full-sized metallic bougie. This course was persevered in for two or three months, and now the testis was reduced to almost its natural size, and the patient stated that its wonted action was renewed.

Fluid from Ranula.

Dr. MOORE exhibited a quantity of glairy amber-coloured fluid, about 3 ounces, which he had removed from the mouth of a middle-aged man in the hospital on the previous day. The patient presented himself with a tumour near the ramus of the jaw, as large as a turkey's egg, which fluctuated; but opening the mouth, the tongue was seen to be pressed aside by a well-formed ranula.

A portion of the tumour was lifted up by the forceps, and about an inch in length of the covering below the tongue was snipped away with scissors. The glairy fluid exhibited flowed out with slight pressure upon the tumour. The sac was then thoroughly emptied, and its lining membrane was swabbed with a strong solution of caustic. Dr. Moore found by the introduction of his finger that no concretion was present. The operation has been followed by complete recovery.

Council Council Meeting February [undated]

President in the chair, Present, Mr. Browne, Dr. Halliday, Dr. Wales, Dr. Dill, Dr. Cuming, Mr. Johnston.

The Treasurer was directed to issue circular relative to defaulting subscribers and form was approved of.

Circular was prepared.

Council Council Meeting February [undated]
Papers wanting Dr. Murney account of post-mortem
of uterine tumour, amputated limbs, fractured skull.

Dr. Heeney Prurigo
Dr. Moore's amputation
Dr. Murney's arm

THIRTEENTH MEETING.

February 4th, 1860.

The President in the Chair.

Case of Hysteria.

Surgeon JOHNSTON introduced a girl affected with what he supposed to be hysteria. She was in a debilitated state, and had menstruated scantily, though regularly. The most marked characters of the case were the frequent recurrence of incomplete *syncope*, without loss of consciousness, apparent *respiratory distress*, and a slight *cataleptic* tendency, as exhibited in the momentary preservation of any altered position of the extremities. Considering debility to be the chief cause of the malady, he had prescribed suitable sanatory measures, together with *chalybeate* and other *hæmatic* remedies, but so far without any apparent effect.

Concurrent opinions as to cause, nature, and treatment of this case were expressed.

Puerperal Observations.

Dr. W. AICKIN exhibited a *placental cord* 4 feet 3 inches long, which had encircled the child's neck five times. The case did not present any remarkable features; the only point worthy of note being the fact that *ergot* had failed to excite uterine action, while *opium* had succeeded. In the course of his remarks, Dr. A. condemned the side as a lying position in advanced labour, and recommended the back, which led to the following observations on the merits of different parturient postures.

Dr. PATTERSON—"The back is the best position during labour."

Surgeon JOHNSTON—"Nothing is gained by separating the knees during the expulsion of the child."

Dr. WALES—"The practice of abducting the knees during expulsion of the child endangers the perineum by advancing and tightening it anteriorly"

Dr. HALLIDAY, in reference to the cord encircling the neck: "It is elongated in proportion to its requirements in this respect."

The PRESIDENT—"Observed the *funis* so much shortened by entwining the neck as to retard labour."

Surgeon BROWNE—"No advantage generally in any particular position in labour, save convenience; uterine action being sufficient to effect expulsion of the child without other muscular aid, as evidenced under the administration of chloroform."

Dr. M'GEE—"Will not agree with Surgeon Browne in ignoring the powerful aid afforded by the respiratory and abdominal muscles."

Dr. DILL—"Most women seek fixed points for muscular action during the throes of labour. If this has a purpose, auxiliary muscular action has its advantages. The left side is the most convenient; and in the obese, separation of the knees during expulsion of the child diminishes resistance. The occasional success of opium in exciting the uterus to action is due entirely to its first or stimulating effects."

Exhibition of Recent Parts.

The PRESIDENT exhibited some morbid parts removed from the body of a female, aged 25, who died of phthisis.

A large amount of tubercular deposit existed in both lungs; and the disease appeared in a more advanced stage in the right than in the left, which had also been indicated by auscultation during life. The liver was very pale, greatly enlarged, and much thickened at its base; its surface was smooth, pitted, and broke down easily on pressure, and was deeply indented by the pressure of the ribs. When a slice of it was placed in the centre of a bright fire, it shrivelled up like a piece of leather, without emitting any sparks or flame; nor was any mark left on paper when a piece of it was laid on it on the heated bar of the grate. As it did not therefore furnish the indications usually relied on as indicative of a deposit of fat, a piece of it was boiled in a weak solution of nitric acid, when it became white—in so far tallying with Dr. Budd and Dr. Beale of what takes place with one test when the deposit is chiefly of an albuminous nature.

Dr. Cuming then examined a portion with the microscope, and found a considerable amount of oil globules; but as some oil might be present when the deposit was chiefly albuminous, Professor Hodges, M.D. kindly undertook to ascertain the percentage of fat, and found it to be nearly 9½, the healthy proportion being about 4, which has been found by Dr. Beale to be reduced to near one, or even so low as one-half per cent., when the enlargement of the liver was due to an albuminous deposit. This chemical analysis proving that the enlargement of the liver was owing to a deposit of fat and not of albumen, the fire and the paper tests were applied again at the end of ten days, when it was found that owing to the evaporation of fluid, and consequent drying of the liver, it now both stained paper and emitted sparks and flame in the fire, thus indicating that before a liver can be pronounced not to be enlarged by fat, care must be taken that it is sufficiently dried when applying the rough and ready tests that were relied on till the introduction of the microscope, &c.

Great dulness, on percussion, existed at the base of the chest, but the enlargement of the liver was so

evident on percussion and to touch, that no difficulty existed in accounting for the dulness. There was neither jaundice nor ascites, and not more œdema of the limbs than is usually present in phthisis. This patient denied that she had ever expectorated blood, nor was any observed during her two visits to hospital.

FOURTEENTH MEETING.

February 11th, 1860.

The President in the Chair.

Congenital Malformation of the Pupils.

Mr. BROWNE introduced a little girl, aged 10 years, in whom there exists a peculiar malformation of the iris in each eye. In the right, the pupil is transverse, and has a double aperture; in the left, the pupil is single, but is also transverse, the slit extending to the ciliary attachment on the outer side, while on the inner side, the iris presents the appearance as if the transverse slit had become united for about half a line in breadth. Both pupils, upon being dilated with atropia, became nearly circular; both apertures, in the right, dilating so as to leave a merely thread-like division of the iris between them. Vision in the left eye is good, but in the right, is very imperfect, in consequence of the anterior chamber having become greatly enlarged from hydrophthalmia. The cornea, and about a line in breadth of the upper portion of the sclerotic, being very much thinned, Mr. Browne expressed it as his opinion, that nothing could be done to remedy these changes of structure in the right eye; but that tonic treatment, rest, and care, might prevent the left eye from becoming dropsical also.

*Impaction of a Pin in the Throat
for Four Months.*

The SECRETARY read the following case from Surgeon M'DONNELL, of Randalstown:—

Catherine M'Gee, aged 61, a country servant, had been in town in September last; on her way home, she put a pin in her mouth, and forgot about it. On getting to her master's, she ate some bread, in swallowing which, she found something prick her at the lower part of her breast. She endeavoured to bring it up by retching, and succeeded so far as to get it to the upper part of the œsophagus. She now found it impossible to swallow anything, either food or drink, and she remained in this state for eight days, when she applied to me. I examined her throat carefully, but could find nothing; however, I passed a probang into the stomach, and this enabled her to swallow, but she complained of pain in doing so. I heard no more about her till the 1st of January, when she came to me, saying she was sure the foreign body still remained, and pointed to a swelling over the thyroid cartilage. On examining this swelling, I thought I could find fluctu-

ation, and made an incision in the median line,—a little unhealthy pus came away, but I could detect no foreign body. I desired her to poultice for a few days, and return again. She did so on the 3rd inst., but I was unsuccessful this time also. She became much alarmed, and requested me to do anything that I considered safe to relieve her. I was cautious in cutting in so intricate a situation. I made my first incision in a V shape, extending the lateral cut along the corner of the thyroid body, and raised the angular flap, and after a long and careful search, I found the head of a pin protruding through the hyo-thyroid ligament, about half-an-inch from the surface. The greatest difficulty I experienced was from the cough produced on touching the deep parts. I would infer from the way it came out, and its appearance—the head and great length of the pin, being oxydized carbon, and the point clear—that it passed across the trachea and pierced the œsophagus; but how it got into this position, and how she tolerated it so long in so important a part, is what I cannot account for; and also the head of the pin appearing first, seems to me strange. I may add, the old woman got immediate relief, and she is now quite well.

Disease of the Heart.

The PRESIDENT exhibited the heart, kidneys, and liver of a female, aged 57, who had died of dropsy.

When first seen, she was found lying flat in her bed, with intense circumscribed lividity of her cheeks and nose, general anasarca and ascites, with lividity of forearms and legs, and pulsation in both jugular veins. She suffered much from cough and dyspnœa, and large crepitation was heard over both lungs. The rales in her chest prevented any correct conclusions being formed as to the state of the heart. When the lung symptoms had been considerably relieved by treatment, a systolic murmur was heard below the nipple, which could be traced with increasing distinctness towards the cuniform cartilage, but not in the direction of the side:—at the right side of the upper portion of the sternum, three sounds were audible, having a striking resemblance to the cantering sound heard often in pericarditis. She continued to assume a perfectly prone position to the last, and died sooner than was expected.

Post-mortem examination found a hypertrophied and dilated right ventricle and auricle, which had permitted regurgitation, and consequent pulsation in the jugular veins. The left ventricle had been laid open, without testing the sufficiency of the aortic valves—a deposit had taken place between the folds of membrane forming these valves, and there was a small vegetation on the aortic surface of two of them; a similar deposit, but to less extent, was found also in the pulmonary valves, but no vegetation. No murmur had been heard at the base of the heart during any of

Belfast Clinical and Pathological Society
Seventh Session: 1859–1860
President James Seaton Reid

these examinations. The kidneys were enlarged and deeply congested, but their structures healthy. On the surface of the left, there was found a cyst containing more than an ounce of fluid. The urine was not albuminous. The liver was enlarged and thickened at its base, where it had several fissures of near an inch in depth. Dr. Murney stated, that he had only met with these in females, and that he ascribed them to the habit of wearing stays—but as these fissures were vertical, it is difficult to account for their production by pressure of this kind.

Observations on Mushrooms.

Professor DICKIE, M.D., made some observations on mushrooms. He said that many varieties of these fungi, which were considered unsafe as food in this country, were used on the continent. Pickled mushrooms and black bread constituted a meal in some parts of Russia. To the *Amanita Muscaria* he called particular attention. After describing its beautiful appearance, he said it was met with in Autumn throughout Europe, and flourished in Colin Glen, in our own neighbourhood. The Kamtschatkans, and other inhabitants of the north-eastern parts of Asia, used it in a *dried* condition, as a means of producing intoxication; and he adverted to the long-known fact of its inebriating principle being eliminated by the kidneys almost unimpaired. In illustration of this peculiarity, he said it was common for an individual, his edible stock being exhausted, to prolong his debauch for several days by the more disgusting debauch of drinking his own urine; and also, that the urine of one who had feasted on the *Aminata* was esteemed by his more degraded companions for its inebriating qualities, who in turn, and through several successive persons, could reproduce the original effects. He next called attention to the physiology of the action on the body of this class of fungi as a field for investigation almost untrodden. So far as known, the poisonous mushrooms might be considered narcotic, the first effect being stimulation, and the second, sleep. In conclusion, he expressed himself willing to aid in a more extended inquiry into their actions on the system. He also said that the mushroom fungus could be developed by exposing ergot of rye in a warm and moist situation.

FIFTEENTH MEETING.

February 18th, 1860.

The President in the Chair.

Dr. MURNEY exhibited several specimens of the shortening of the neck of the femur from injury *without* fracture, which were interesting from the liability to error in diagnosis. His remarks will be given in detail in Appendix.¹

¹ [Not available.]

SIXTEENTH MEETING.

February 25th, 1860.

The President in the Chair.

Cases brought forward at this meeting by Professor Gordon, Dr. Moore, and Dr. W. Aickin, on chimney-sweeper's cancer, medullary disease of testis, destructive ulceration of fore-arm, and carcinoma in sub-maxillary region, have not yet been furnished to the Secretaries, but will be given in Appendix.¹

SEVENTEENTH MEETING.

March 3rd, 1860.

The President in the Chair.

Dr. WALES introduced a child suffering under chronic hydro-cephalus. The head was greatly enlarged and increasing, and yet the little patient was improving in general health. Dr. W. observed, that the child's mother was lying under well-developed small-pox when he delivered her, and he considered the absence of the disease in the child an interesting fact.

Dr. HARKIN exhibited a girl having a small encysted tumour above clavicle, which, from pulsation derived from the carotid, simulated aneurism.

*Case of Compound Comminuted
Fracture of Tibia and Fibula.*

Surgeon BROWNE stated that the specimen before the Society was taken from the leg of a patient at present in hospital, and which had been amputated after an attempt to save the limb had been persevered in for nearly four weeks. He stated, also, that the specimen which he exhibited was a beautiful illustration of the lesion sustained by the bones of a limb from direct violence—the result, in fact, of a heavy body having passed over the leg while it was extended, on its outer side, on the ground. It would be observed, that about an inch below its centre the tibia is fractured obliquely, with a small detached portion; opposite this point there is an oblique fracture of the fibula also. About three inches lower down the tibia is again fractured transversely, the posterior part of the bone being comminuted; the part of the bone between the oblique and transverse fractures is detached and displaced outwards above, its upper point pressing against the oblique fracture of the fibula. It was, he might remark, at these points—at either end of the separated portion of the tibia—that the injury had become compound, as a wound extended through the soft parts to the bone. Then a little above the inner malleolus there is a split into the structure of the bone, perpendicularly for an inch and a half, extending towards, but not into, the ankle joint. The fibula is likewise again broken a little above the outer malleolus. It would be further observed, that the detached

portions of the tibia and fibula are stripped of their periostum, and are becoming necrosed.

The immediate cause of amputation, was the amount of suppuration which had taken place, and which was daily increasing—and it would be seen from the specimen before the meeting, that there was no other resource to give the patient a chance for life. Indeed, it is now clear, that from the first there could not have been any reasonable prospect of saving the limb, and it is to be regretted, that primary amputation had not been resorted to. However, in these days of conservative surgery, and as he had not the consent of his colleagues, he did not urge what all along he believed to have been the safest step for the patient.

The question of primary amputation is one of vast importance, and is one, also, frequently of very difficult solution; still, in cases like the one under consideration, the difficulty is, in some measure, removed—as every hospital surgeon must be aware, that in injuries arising from very heavy bodies passing over a limb, there is often, very generally, a much greater amount of lesion, both to the bones and soft parts, than what is indicated by the eye; and that, in these cases, the attempt to save the limb is not only a hopeless proceeding, but exposes the patient to greatly increased risk. In corroboration of these remarks, his hospital experience had afforded him many examples, and he had, on more than one occasion, to regret some attempts at preserving limbs, which after circumstances had proved to have been wrong in the first instance.

The patient now under notice is doing pretty well, and he hoped would eventually recover.

Dr. ROSS read the following paper

On Typhoid Fever.

Of late years it has been much insisted upon, by many able clinical observers, that typhus and typhoid are different forms of fever, and my own experience leads me to believe that the distinction is well founded and has important practical bearing. The few following remarks will apply to the *Ætiology*, *Pathology*, *Semiology*, and the *Therapeutics* of typhoid fever.

Ætiology.—It has been a matter of much controversy whether typhoid fever is infectious or not infectious, which I believe it to be not at all so much so as typhus—Cases have occurred to me in which it appeared to be undoubtedly propagated in this way. I consider the alvine evacuations more than any of the other excretions, a fertile source of its communication from person to person, and that it is prudent to act on this opinion, and to pour some solution of chloride of lime into the bed-pan before using it, and to have the defecations removed from the patient's bed-room at once, and so disposed of as to have as few individuals as possible exposed to their poisonous

influence. Defective action of the excreting organs seems to have some influence in the causation of typhoid fever, and in this way I account for its being occasionally a sequel of long-continued delicate health. To neglect of the laws of hygiene, as unhealthy residence and bad sewerage, its origin is most of all attributable. This has been well exemplified in the Windsor Epidemic.

Pathology.—In this disease there is a peculiar fever poison in the blood, and, as in other constitutional affections, so in this, nature tends to throw off the poison by elimination. To Peyer's glands the *materies morbi* is remarkably directed, causing their enlargement, congestion, and too often their ulceration. Thus I view the morbid changes of these bodies, which are so pathognomonic of typhoid fever, as an invariable complication, and not, as some would have us believe, the *fons et origo* of the mischief. Allowing for the difference between an acute and a chronic disease, we may see some analogy between the destruction of Peyer's glands by the fever poison, and the injury to the kidney by the gouty poison. In each case the organ does nature's work, excretes a poison from the system, but in doing so may suffer more or less disorganization.

Semiology.—No symptom is so diagnostic of typhoid fever as diarrhœa, coming on during its course without any assignable cause, or after a mild aperient, and obstinately resisting treatment; with the looseness, gurgling over the ilea cœcal valve, and tympanites, are generally combined. Gastro-enteric derangement, foul tongue, and fœtid breath, generally precede the diarrhœa. Chest affections are frequent complications, particularly latent bronchitis, indeed I don't recollect meeting with a case in which the pulmonary mucus membrane was not engaged in a greater or lesser degree. In the early stage only a few rales may be heard, but these often extend, pass through the dry and moist characters, and implicate both lungs. The cerebral functions are often disturbed, and I have been often struck with the alternation between the delirium, bronchitis, and diarrhœa. A rose-coloured rash over the chest and abdomen is another most important sign of typhoid fever. The constitutional affection is indicated by the febrile symptoms, as quick pulse, hot skin, loaded urine, general depression of the vital powers, and pains over the body and limbs.

The difference in the countenance of one in typhus and one in typhoid fever is marked. In the former, from an early period, the face is confused, oppressed, and congested. In the latter, there is an absence, at least in the early stages, of these signs, and the patient is more intelligent when addressed.

It is now well established that typhoid fever is chiefly confined to the ages from 15 to 30—not so typhus.

The duration of typhoid fever is much longer than that of typhus. While in the latter a crisis generally comes on about the 14th or 15th day, typhoid is not unfrequently of several weeks' duration, exhausting the patient, and also his physician and relatives.

Treatment.—The important rule of supporting the system until nature effects a crisis is as necessary in this form of fever as in the other varieties.

The entire affection indicates a bland and farinaceous diet; but there are few cases in which, as the disease advances, wine or brandy and animal broths, with arrow-root, do not become necessary. Much discretion, however, is required in the use both of food and stimulants.

Whilst using these general means, we must keep a strict look out for the complications. If there be head affection, the hair must be cut off, and cold lotion or affusion used at intervals. Leeches and henbane will be useful if there be sleeplessness.

If there be much chest affection, we must be sparing in the use of full opiates, and we will find sinapisms and blisters, hippo, camphor, and ammonia most useful aids, if employed with discrimination.

But of all the complications, the diarrhoea requires the most careful management, preventing it, as much as possible, by regulation of diet, and by abstaining from purging. When it does become troublesome, the opiate enema, chalk mixture and catechu, lead and opium, and counter-irritation of abdomen, are the remedies which I have used with the most benefit.

Attention to the bladder, the prevention of bed-sores, general cleanliness, and pure air, are, I need scarcely say, indispensable to the safety of the patient.

EIGHTEENTH MEETING.

March 10, 1860.

The President in the Chair.

Case of Elephantiasis of Penis.

Dr. CORRY introduced a young man, aged 22, by occupation a labourer, affected with elephantiasis of the penis. The history of his case was rather peculiar. He stated that about six years ago he had one day fallen asleep in a field, exposed to the glare of a scorching sun, from which he was awakened by an acute pain in his genital organs; this continued for several days, and prevented him following his usual avocations. From that date his penis has gradually increased in size, and he has had a periodical return of the pain about four times each year. On examination, the penis was found greatly hypertrophied, presenting a fine specimen of the true Elephantiasis Arabum; it measured seven inches in length, and in circumference, five inches at root, seven inches at body, and six inches at glans. The organ had a hard, horny appearance, being intersected by several deep fissures, and studded over

with a number of small tubercles; the prepuce was much thickened, and had completely lost its distinctive character. The disease, which had evidently commenced in the penis, was gradually extending, the scrotum and inner parts of the thighs having become implicated.

This case created considerable interest among the members on account of its extreme rarity in this country.

Dr. PURDON said the disease was endemic in Kilkenny.

Dr. C. D. PURDON read the following observations on

The Use of the Hypo-Phosphates.

The hypo-phosphates were first brought under the notice of the profession by Dr. Francis Churchill, of New York, who then stated that he had found the use of them to be very successful in phthisis, but the results in this country not being so very favourable, the preparations had fallen into disuse; but having tried these remedies frequently in gastric afflictions of children with great benefit, I again bring them under your notice as most useful remedies in these diseases. The first case in which I used these remedies, was one of chronic remittent fever, which had persisted for one year and a-half in spite of all remedies, and the little patient was rapidly sinking, and from the state in which she was in, there appeared no release from suffering but death. I may mention the symptoms, viz.—loss of hair; dark coloured rays under the eyes; point of nose red; aphthæ at either commissure of the mouth, as well as in the mouth; gums spongy; tongue covered with a creamy exudation, which frequently exfoliated; abdomen tympanitic, with enlarged inguinal glands; constant diarrhoea, with clayish-coloured stools frequently, at other times rather dark coloured and mucous, always offensive; frequent prolapsus of the rectum, which was dry and glazed and aphthous; vulva covered with aphthæ; limbs wasted, and body covered with small boils; skin dry and rough. As a last resource, I tried the hypo-phosphates, and after persevering in their use, the child rapidly improved, and is now a fine healthy one.

The next case in which I used them was a child that had been under treatment for several months for remittent fever, and was wasting away as children usually do in that affection, no remedy having any permanent effect; and on having recourse to them, the child gradually improved, and the hectic fever, as well as the other symptoms, abated, and the child became quite convalescent.

I have used these remedies in cases where there was gastric irritation with good results, and from the great improvement that I have witnessed from their use, I can confidently recommend them as a most valuable remedy in gastric and mesenteric affections.

As to the manner in which I use it—I always, in gastric fever, try to improve the character of the bilious secretion; and, should the disease continue after the natural-coloured stools are obtained, then I have recourse to it. In the case of gastric irritation, I give them at once, in syrup, three times a day on an empty stomach.

“Respiratory Distress” No Longer a Pathognomonic Symptom of Fatty Degeneration of the Heart.

The PRESIDENT made the following communication:—

A remarkably well-formed man sought Hospital relief in consequence of his suffering from cough and dyspnoea, and latterly from anasarca. During the night after admission, he had a severe paroxysm of dyspnoea, which caused him to rush into the lobby for air, and made the night-nurse raise the Resident Surgeon to see him. At my visit next morning, I was struck with the peculiarity of his breathing, and his position in bed, and elicited from him the following history:—

He stated that he was by trade a cooper, and that his age was 56, although he looked at least ten years older. During the last two years he had been subject to cough and dyspnoea, and was compelled to lie almost constantly on his left side; but he had never expectorated any blood. For six months past he had suffered much from pain in his shoulder, neck, and head, on the right side, but never on the left, nor had he at any time an attack of acute rheumatism. His legs had been œdematous during the last half year. Some months ago he had a “catch in his breathing” similar to that of last night, which compelled him to run into the street for air; and he pointed out the seat of his suffering to be between the Pomum Adami and upper edge of the sternum; and was certain he had never had any dysphagia.

Increased pulsation *was seen* in the carotid and subclavian arteries, and was more manifest at the right sterno-clavicular articulation than on the left. A feeble, undulating pulsation was also seen between the third and fourth intercostal spaces on the right side near the sternum, but none on the left.

Strong pulsation *was felt* at the right side of the sternal notch, and in behind the insertions of the sterno-cleido mastoid muscle, unaccompanied with thrill; and both subclavian arteries expanded much, just where they escaped from under the clavicle.

A single murmur *was heard* in the carotid and subclavian arteries, which became double under the top of the sternum and sternal end of right clavicle, and continued so as low down as a line on a level with the left nipple. A single murmur could be heard about two inches lower, and to the left, in the region of the apex of the heart.

The impulse of the heart is entered in my case-book as “fair,” so that it was neither unusually feeble, nor in excess; nor was any heaving expansion of the

chest to be seen or felt when it was examined in profile.

Both pupils were natural.

On watching the peculiarity of his breathing, it was found to be an example of the “Respiratory Distress of Stokes”¹ on that day, unaccompanied with moaning, and much less intense than it became subsequently, but still presenting its peculiar ascending and descending scale.

When a paroxysm of the distress had terminated, and that the breathing had become quiet or had ceased for a time; he would then be attacked with a fit of coughing, which afforded no relief, as he was unable to obtain any expectoration. During the fit of coughing both external jugulars, and a large vein crossing just above the sternal notch, were distended to a size not less than that of the fore-finger, without any pulsation being observed in them. The pulse, if counted during a minute, would be described as irregular; but presented that *regularity in its irregularity*, which several members of this Society had an opportunity of witnessing last year, in two of the aneurismal patients whose histories I brought before you, and in whom the symptom of Respiratory Distress was also present.² This patient was therefore the third, during the last twelve months, in whom I had observed, that during the paroxysm of “distress,” *the pulse became invariably slow when the distress was greatest, and as invariably quick when it was subsiding, or whilst the patient had ceased to breathe.* I am therefore disposed to believe, that this is not “a mere coincidence,” but that it and the distress stand towards each other in the relation of cause and effect; and as I find no mention of this peculiarity in the pulse by any writer on cardiac pathology, I believe I may claim to be the first who has noticed its association with the Respiratory Distress. Neither it nor the distress, is to be found equally marked or intense on every day, for, as in other cases of suffering, the patient has his “good days” and his “bad days,” his hours of comparative ease as well as of severe suffer-

¹ It may not be out of place if I quote a description of a paroxysm of the Respiratory Distress. I shall presume that one has just terminated:—“After a period of apparently perfect cessation of breathing, the faintest possible inspiration takes place, succeeded by one a little stronger and longer; the respirations then gradually increase in strength and depth, till the respiratory act is carried to the highest pitch it seems capable of; when the head is thrown back, the shoulders raised, and every muscle of inspiration thrown into the most violent action, accompanied often by a loud moan from the patient. When the respirations have reached this maximum, they pursue a descending scale, and commence to regularly diminish in strength and fulness, until they apparently cease;” when, as some members present saw in one of my patients last year, the sufferer may say—“Now, I am quite well;” or the respiration may cease for so long as to impress a looker on, as it did my nurse in this case—“Sir, his breath stopped for so long that we thought he was dead.”

² Transactions of the Belfast Clinical and Pathological Society, p.97, 1858–59.

ing. Innumerable opportunities, however, were afforded me of pointing out the peculiarities of both to my Clinical Class and some medical friends; and I had also, the gratification of being able to show them in full intensity to Surgeon-Major Pilleau, M.D., and to Staff-Assistant Surgeon O'Brien, M.D., when I had the pleasure of a visit from them at the Hospital. The pulse at the wrist varied in strength and fulness, but in the brachial arteries it presented the well-marked character of the "jerking pulse," and occasionally also in the radial artery.

During the ten weeks this patient was under observation, I never found him lying on his right side but once; his usual position was leaning on his left elbow, with his head about a foot off the pillow; occasionally resting it on his hand, which was, no doubt, the cause of a varying œdematous state of his left arm and forearm. He had most ease sitting up with his feet hanging over the side of the bed, and although at the very side of the fire, and that he had abundance of clothes, he was always complaining of cold. His sufferings were generally increased in the evening, and he insisted at night on being allowed to sit before the fire with his bedclothes wrapped round him. This necessarily led to considerable dropsical swelling in his legs, which, indeed, vesicated and burst, and were with difficulty healed. At no period of his illness was there any ascites, or œdema of the face—nor was the urine albuminous.

In the two other patients with Respiratory Distress there was a constant craving for stimulants, but such was not the case with him; for although he was aware that several hours of severe suffering would be relieved in a few minutes by a couple of ounces of whiskey, he had generally to be solicited to take it.

With respect to the diagnosis in this case. The double murmur at the base of the heart, and the single murmur at the apex, warranted the conclusion that both the aortic and mitral valves were incompetent to close their respective orifices. In support of this view we had also the "visible pulsation" of Dr. Corrigan in the carotid sub-clavian and brachial arteries; but not to be seen so distinctly in the radial. We had, however, in addition, some of the symptoms that I had observed in the female who suffered from the fusiform aneurismal dilatation of the aorta and innominata (but without any imperfection of the aortic valves) the diseased structures of which I exhibited here last session.¹ I therefore concluded, that a similar lesion existed in this patient, for he had also suffered from pain in his shoulder, neck, and head, confined exclusively to the right side; accompanied by a pulsation to be felt and seen at the right of the sternal notch, and in behind the insertion of the sterno cleido mastoid muscle.

¹ [See page 790.]

In the female referred to, and also in the third aneurismal case, in which there was every reason to believe that the aorta and innominata were also dilated (though a post mortem examination was refused), there appeared some time before death, œdema of the right mamma, and upper part of the right side of the chest.

This did not take place in this patient, which was probably owing to the incompetency of the aortic valves, preventing the possibility of *continuous* pressure by the dilated arteries on the right vena innominata.

But the chief diagnostic interest in this case is connected with the symptom of Respiratory Distress, to which Dr. Stokes was the first to assign a diagnostic interpretation; making its presence pathognomonic of fatty degeneration of the heart, as he states¹ "that he had never seen it except in examples of that disease." I had only been able to obtain a post mortem examination in one of the other patients, in whom this symptom was present; and as fatty degeneration of the muscular fibre of the heart existed in her, I continued to look upon it as a symptom that might be relied on as indicative of the presence of that particular morbid state. I therefore added to the diagnosis of fusiform aneurism of the innominata and aorta, with incompetency of the aortic and mitral valves, the further lesion of fatty degeneration of the heart.

I am unable to offer anything but a speculative explanation of the undulatory pulsation that could be seen, but barely felt, between the third and fourth intercostal spaces on the right. If we admit that the regurgitation through the mitral orifice would so impede the circulation through the lungs, as to prevent the right side of the heart having free action; then a distended state of the right auricle might be the cause of a feeble pulsation in this locality. This is the second occasion in which I have observed this symptom. The first was in a patient of Dr. M'Gee's, with enormous hypertrophy of the heart. It is a symptom of some interest, as its locality would suggest the idea of a sacculated aneurism, though it is deficient in the expansile force of an arterial pulsation.

Having the good fortune to obtain a post mortem examination, I again availed myself of Dr. Murney's well known microscopic and anatomical knowledge, to obtain for the Society an accurate examination of the state of the morbid parts that had been removed, which was granted with his characteristic readiness to oblige, and he reports as follows:—

"The heart, when divested of extraneous matter weighed 27 oz. There were several 'lymph spots,' apparently between the serous membrane and the muscular structure; one, of several inches in extent,

¹ Stokes on Diseases of the Heart, &c, p.324.

on the right ventricle. The hydrostatic test showed the pulmonic valves to be perfectly competent, but the aortic semi-lunars were quite incompetent—on each of its three divisions a hard calcareous-like deposit was found. On the back of two of these, little wart-like growths projected from the surface. There are a few soft wart-like vegetations on the mitral valves. The left ventricle is considerably dilated; its walls very much thickened, measuring at its middle $1\frac{1}{8}$ inch; the muscular structure firm, and without any trace of fatty degeneration, when carefully examined by the microscope. The right cavities and valves are normal, and without any dilatation of the venæ cavæ. The lining membrane of the aorta was thickly studded for several inches with atheromatous deposit. The aorta and innominata were dilated, and, in order to note the extent, they were compared with a healthy specimen. When both were slit open and spread out, it was found that the aorta in the healthy specimen measured, transversely, $2\frac{1}{2}$ inches immediately above the semilunar valves, and the innominata, before its bifurcation, $1\frac{1}{8}$ inch; whilst in the diseased specimen they measured at the same parts respectively 4 inches and $1\frac{3}{8}$ inches. There was calcareous and atheromatous deposit in both coronary arteries, which were also dilated."

I need not say how disappointed I was to find that Dr. Murney's microscopic examination of the structure of the heart had proved it to be free from fat, and that the symptoms of Respiratory Distress must henceforth cease to be looked upon as pathognomonic of fatty degeneration of that organ.

Before communicating this result to the members of this Society I felt bound, in justice to Dr. Stokes, as well as for the interests of science, to have Dr. Murney's opinion either confirmed or disproved; and I, therefore, wrote to my friend Dr. S. Gordon, of Dublin, requesting him to have the slices from base to apex of both ventricles, which I forwarded, thoroughly examined with the microscope, which he was kind enough to do, and says, in reply—"The result of my enquiries as to the condition of the heart-fibre which you sent me for microscopical examination, is that it is quite healthy. One gentleman writes to me, 'it is quite healthy, even up to the fat under the "white spot" there is no degeneration; under the said spot, there is some common yellow fat. As in all negative cases, this result has only been arrived at, after a careful examination of several parts of the specimens. The glass used was Smith and Beck's one-fifth.'"

A similar opinion as to the absence of fat was given by several others, who examined it for Dr. Gordon.

No practical physician likes to part with a symptom that has been held to be pathognomonic, and, therefore, further observation must determine, whether Respiratory Distress may be found associ-

ated with any other lesions of the heart than fatty degeneration, and those present in this patient. I would be disposed to think that it would not, because a little reflection will suggest to any one how similar the state of the circulation must be in the minute capillary vessels of the brain, upon which the integrity of the nervous system depends, produced by fatty degeneration of the heart, and by regurgitation from the arteries into the aorta, then into the ventricle, and again into the auricle; and how difficult it would be to find a lesion that would produce a similar effect on the brain, which I believe to be the cause of this Respiratory Distress. And should further observations prove this limitation, it is evident, that, as the stethoscopic and other symptoms would generally ascertain the existence of regurgitation, when it was proved absent, Respiratory Distress would still remain a most valuable diagnostic symptom of the presence of fatty degeneration, though this case removes it from the higher position of being pathognomonic.

I shall not, however, enter on any speculations on this point, feeling that I have only been justified in occupying so much of your time, in consequence of the points of diagnostic interest that were connected with this case, and that the exhibition of morbid structures here, are chiefly of value in confirming or rendering more accurate our means of diagnosis.

I have now only to mention the state in which the post mortem examination found some other structures. There was no effusion into the pericardium or peritoneum, but there was a considerable amount into both pleuræ; the left lung was quite healthy, but there were very firm adhesions of the base of the right lung to the diaphragm; and bands of several inches in length between the sides of the chest and the surface of the lower lobes. The liver was healthy. On the spleen there was a depressed spot, with calcareous deposit in it. The left kidney was very small and lobulated, but its structure healthy; whilst the right was very large, and had a considerable amount of fatty deposit in its cortical structure.

NINETEENTH MEETING.

March 17th, 1860.

The President in the Chair.

Necrosis of Femur.

Surgeon BROWNE exhibited a portion of the left femur, which he had amputated on the preceding Monday for necrosis. The history of the patient, a lad of 15 years, was, that about six years since he had injured the limb in leaping, that suppuration immediately above the inner condyle had taken place, and that some portions of bone had been cast off. For the last four years, up till six weeks ago, the limb had been pretty well. Within the past two months he had begun

to feel pain above the knee, and to walk with a halt; there was some swelling and tenderness of the soft parts. Two weeks since he applied for admission to the General Hospital, and could still bear his weight on the leg, and walk. On admission it was found that a strumous abscess had formed on the outer side of the thigh, a few inches above the knee; this was opened, and discharged some unhealthy grumous matter. About a week after, in attempting to get into bed, he heard a crack, felt something give way, and immediately observed deformity of the part. At first it was imagined that the epiphyses had separated from the shaft of femur; but further examination showed a spontaneous fracture had taken place four inches above the knee. Extensive suppuration followed, with marked symptoms of hectic, and, on consultation, amputation was decided on. This operation was performed, under the influence of chloroform, by the long anterior flap, made from without inwards, and a short posterior flap made by transfixing the limb. The bone was sawed above the middle third, and was found healthy. On cleaning and examining the amputated bone, traces of the old inflammation and exfoliation were visible, and a rugged portion through a necrosed shaft some five inches above the condyles. This point was very much thinned and discoloured, without the smallest sign of any attempt to repair.

The point of interest is, that the patient could have used such a limb up to within a fortnight of its having given way under slight exertion.

Since the operation the little fellow has progressed most satisfactorily, the hectic has entirely ceased, and there is every prospect of his being quite well in the course of a month.

Dr. GRAVES, of Cookstown, read the following

Case of Gastric Parasites.

Some months since a patient came under my notice in the Cookstown dispensary. A young woman about 24, in phthisis, in the second, and verging on the third stage. In the physical signs there was nothing unusual, nor in the symptoms, save that she complained of frequent severe deep gnawing pain at the epigastrium, very irregular and intermittent, but generally worse when the stomach was empty. I saw her one evening suffering severely and prescribed a draught with morphia and hyd. acid. On the following morning her mother brought me the specimens contained in this bottle and told me the girl had slept well and comfortably during the night, that while dressing she was suddenly seized with pain and vomiting, and that these parasites were ejected on the floor. Instant relief followed. This is the only history of the case I can give. But let it be remembered, from this date the gastric symptoms entirely ceased. She lingered for some weeks, and was carried off as we had foreseen, by pulmonary consumption.

I must confess these worms puzzled me not a little. I have never seen any similar, nor can I in the limited references at my command, find any description of them. When brought to me, some two or three hours after their ejection, they were exceedingly active, of a deep straw colour (the spirit has darkened them), and rather elastic to the touch—reminding me much of a grub I have seen in turnip fields. One I sent to my friend Dr. Hay in Dublin, who submitted it for observation to Professor Bache. I much regret having mislaid the Professor's most courteous letter. He pronounces them to be the "meal worm," and suggests that the girl might have eaten some unsound meal in which the ova might have been conveyed to the stomach. It is not unusual for farm servants to help themselves to the *raw material* while preparing "porridge," but on this point I could obtain no information. I find a curious case in the last vol. of Rankin's *Hosp. Prac. Assist.* recorded by Mr. David Dickman, extracted from *the Lancet*, October 1st, 1859, in which a girl of 12 vomited seven or eight garden slugs, the smallest two inches long, and all alive. Some others—supposed from the patient's sensations who "felt something crawling up her throat," and "frequently introduced her fingers to seize what she felt,"—were killed by repeated doses of ammonia and camphor.

After stating that the girl had an unusual craving for fresh vegetables during her illness, the author goes on to say [I quote from Rankin]:—

"The three slugs that came up first were not preserved; but the five others have been kept alive and fed on vegetables, which they preferred being cooked, having at first refused to eat them raw. They are now fed on raw vegetables."

I regret I did not know this before, otherwise you might have had those curious specimens of "our fellow-lodgers" alive and active before you, with a small stock of oatmeal as their entire subsistence.

Dr. CORRY read the following

Case of Epileptic Puerperal Convulsions.

Feb. 25th, 1860.—At 8 A.M., was called to see Mrs. G., aged 21, who was suffering from severe epileptic convulsions. On enquiry I ascertained she was eight and a-half months pregnant of her first child, and had, for several weeks past, been affected with giddiness, headache, digestive derangement, and anasarca of face, upper and lower extremities. The primary attack occurred at 9 A.M. the previous day; but as her friends attributed it to a fright she had received, little alarm was at first created, however, during the day, the paroxysms increased in frequency and violence, though she was conscious during the intervals. About 9 P.M. the symptoms became greatly aggravated, and from that period she had remained in a state of insensibility. On my arrival I found her skin hot, face flushed, eyes injected, breathing laboured, pulse, 140 firm; on

examination, the os uteri was discovered low in the pelvis, but firmly contracted. Ordered two drops of croton oil, and six leeches to the temples, head to be shaved and ice applied, also a blister to nape of neck, and an enema of castor oil and turpentine.

12, noon.—Paroxysms more frequent and severe, face greatly swollen, livid, and distorted, bloody froth exuding from the mouth during each attack, breathing stertorous, pulse 155, very firm, involuntary discharge of urine and fæces, os uteri dilated about the size of a shilling, bled from the right arm to the extent of thirty ounces.

1.30, p.m.—Skin cooler, pulse softer, but still very rapid, paroxysms greatly diminished in intensity. On examination, found os uteri fully dilated, and child's head low in pelvis; introduced the short forceps, and in a few minutes delivered the patient of a stillborn male. Shortly afterwards, during a fit of convulsions, the placenta was expelled, the uterus contracted well, and there was no tendency to hæmorrhage.

4, p.m.—Symptoms much improved, though patient still continues unconscious, has had only two attacks since delivery, countenance pale, pulse 120, soft, introduced a male elastic catheter, and obtained about one ounce of urine, free from blood or mucus, for chemical examination.

9, p.m.—Has had only one attack since last visit, remains in a comatose state, bowels have acted freely, and blister has risen well.

26th, 9, a.m.—Has had only one fit during the night, slept well, and is now conscious; but does not incline to speak much, skin cool, pulse 115.

9, p.m.—No change since last visit.

27th, 12, noon.—Continues to improve, pulse 112, no abdominal tenderness.

28th.—Still improving, skin cool, pulse soft, 110, no evacuation from bowels since 26th instant, ordered six drachms castor oil.

Since the last date she has progressed favourably, and is now convalescent.

Remarks.—As with some members of the medical profession there has of late been a feeling adverse to blood-letting in the treatment of puerperal convulsions, I have been induced to bring forward the foregoing case, as I believe it was one in which the free use of the lancet was required. I had previously availed myself of the various remedies recommended by the most recent writers on the subject, but without success, and it was not until after thirty ounces of blood was abstracted that relief was afforded. It may be suggested that this was not a case of albuminuria, however, such was not the fact, as upon subsequent examination of the urine, I found albumen present in large quantities. There are several strong reasons in favour of venesection in puerperal convulsions, accompanied by vascular plethora; it acts as a powerful sedative, and tends to preserve the brain from

injury during the convulsion, assists in dilating the os uteri, and greatly diminishes the tendency to abdominal inflammation.

Dr. CORRY, in reply to the observations of several members of the Society, was strongly of opinion that the line of treatment followed in the foregoing case, was in accordance with the views of the most recent writers on obstetrics. He was by no means an advocate for the indiscriminate use of the lancet; but in this instance, the free abstraction of blood was followed by such favourable results, that he considered it his duty to report the case to the Society.

Dr. MOORE introduced a person from whose foot he had found it necessary to remove the metatarsal bone of the great toe. No retraction of the toe had taken place, and the perfect use of the foot was preserved.

TWENTIETH MEETING.

March 24th, 1860.

The President in the Chair.

Dr. CORRY introduced a young woman who had suffered from

Laceration of the Cornea.

He gave the following details of the case:—

“May 1st, 1858.—I was sent for to see Agnes Smyth, aged 20, who had received severe injury to one of her eyes from the shuttle of a steam-loom, which had penetrated the sclerotic, producing a lacerated wound extending across the cornea, and dividing that texture. From the formidable nature of the accident there appeared little chance of preserving vision; however, I as soon as possible brought her under the influence of mercury, at the same time applying anodyne lotions to the injured organ, and producing dilatation of the pupil by belladonna. This course was pursued for three weeks, by which time the wound had completely healed, leaving a white line or cicatrix which has now partially become absorbed; and there is little deformity.”

Dr. W. MAC CORMAC read the following

Observations on the Syphilitic Poison.

In laying the following observations on syphilis before the Society, I cannot claim its attention on the score of saying anything new, or perhaps, anything which is not known to most of its members; but the subject is interesting in itself, and from the fact of the large proportion of the human race it affects, our best skill and attention will be demanded in furthering the better knowledge of its nature. Mr. Solly of London propounds a doctrine, which, if carried out to its fullest extent, would prevent the administration of a dose of medicine for the treatment of syphilis. I think his tenets are hardly consistent with true philan-

thropy, nor would I rank Phillippe Ricord among the least of the many benefactors which medicine has conferred on our kind. He it was who, in conjunction with Cullerier, first developed the rational treatment of the disease. It was Cullerier who rescued the unfortunate sufferers from the dungeons of the Bicêtre, where they were confined, often enduring the utmost hardship, till released by death from their tortures.

Having attentively followed the clinique of Ricord for nearly a year, I have become more or less imbued with his doctrines. He acknowledges two forms of the so-called primary disease, viz., the soft and the hard chancre. The first, known by its peculiar worm-eaten appearance, its tendency to be multiple, its extreme contagiousness, and usually the presence of a suppurating bubo in the groin, from the pus of which the chancre may be reproduced by inoculation, and lastly, by the absence of all constitutional affection. The second variety, known by its peculiar hardness, the multiple induration of the glands in the groin, subsequently those of the neck and elsewhere, without suppuration, by its being single usually, and non-inoculable, and lastly, by the inevitable occurrence of secondary symptoms in a space of a month or six weeks, sore throat, roseola, falling out of the hair, &c. In the first case, local treatment alone is required; in the second, constitutional measures are imperative. That these well-marked distinctions exist, I have ascertained, scores of times, in the wards of Midi, and have been able to trace their progress for myself. In my own mind, I am convinced of their truth. The soft chancre exists in far greater proportion than the hard. M. Puche in 10,000 cases, collected in from 1840 to 1852, found the ratio 4 to 1. The soft chancre may attack the same subject several times, while, except in the rarest instances, the victim of a hard chancre is not again liable to the disease. The soft chancre reproduces the soft chancre, whether on the same or another individual, and whether these individuals have suffered from syphilis or not, except in certain exceptional cases which I shall afterwards endeavour to explain, while the hard chancre only once affects the same individual, and is not transmissible to a person who has had constitutional syphilis. Thus it is that the doctrine of syphilisation falls to the ground. It is but the reproduction *ad infinitum* of the soft chancre in the same individual. Lindmann, who inoculated himself upwards of 2,200 times, did not attain the desired saturation; and some of the more celebrated expounders of the doctrine, Hebra and Sigmund, of Vienna, will not assert that the most thoroughly syphilised persons possess an entire immunity. The contrary has been established, in fact, by Ricord, who has more than once exposed the fallacy of this pretended protection with the point of his lancet. Before the time of Hunter, and since it, down to

our own time, the different forms of the malady were ascribed, not to any modification of the virus, but to such causes as a different constitution, temperament, &c.—in fact, the unity of the virus was universally admitted. Several modern writers have sought to explain the different manifestations of the syphilitic poison by adopting a plurality of causes. Carmichael was among the first who mooted this idea. He proposed to recognize four distinct forms of virus, each the antecedent of a peculiar variety of the disease. This theory, however, could not stand the test of a more extended experience. It has yielded in later times to the doctrine formularised by Ricord and his followers, viz., that there are but two distinct primary manifestations of syphilitic poison,—one the hard or infecting chancre, the other the soft or non-infecting chancre. Bassereau further believes that each of these varieties transmits itself as a pathological species, and cannot engender the other. Bassereau attempts to establish his position by historical evidence. Up to the end of the 15th century, gonorrhœa, chancre, buboes, were described by writers on these subjects, as diseases merely requiring local medication, and in no instance were any sequelæ to these diseases mentioned. The end of the 15th century, however, is stated by contemporary writers to have been marked by the appearance of a new disease, the symptoms of which were similar to those now described under the titles secondary and tertiary syphilis, and for the treatment of which constitutional measures were necessary. When Bassereau asserts that the one form of sore is not convertible into the other, he is mistaken, as, under peculiar conditions, as I shall afterwards strive to explain, a hard chancre may be transmitted to another individual under the form of a soft non-infecting sore, while authentic instances are also recorded when the soft chancre will produce the hard infecting sore with all its sequelæ in the economy. Bassereau and Clerc, as well as Diday and Rollet, of Lyons, from their personal experience, state that the hard chancre transmits itself in its own form. Ricord cites fifty-nine examples in which the origin of the disease was traced, and in each case, without a single exception, the relation was found to hold good. In all these cases, however, the subject to whom the chancre was transmitted by contagion, was free from all syphilitic antecedents. In the case of persons who have previously had syphilis, the question becomes changed. Let us now inquire if the hard chancre always owes its origin to a chancre of a similar nature, or can give rise to any other form of primitive sore. It has been established by the syphilisators, though the result had been an undesired one, that the ordinary soft chancre in a person free from constitutional syphilis, can only recognise for origin chancre of the same nature. There is, however, another variety of soft chancre, undistinguishable, save by its origin,

from the usual kind. It is the chancre produced in a person who has had syphilis, by the contagion of a hard or infecting sore. This, in virtue of the unity of the syphilitic virus, does not indurate, it presents the usual characters of a soft chancre; and, according to M. Clerc, who has given it the title of chancroid, should perpetuate itself in that form, totally irrespective of its origin. But the question now arises, whether this so-called chancroid, if transmitted to a third person, free from all syphilitic antecedents, would retain the non-infecting character, or take on the infectious nature of its origin. This is a point which cannot be very readily cleared up, from the number of elements concerned in its solution. There is a less complex problem, however, which has been satisfactorily answered, viz.: can a person having had constitutional syphilis, the subject of a new chancre, which must, of necessity, be a soft one, transmit to another individual hitherto free from syphilis, a hard chancre, followed by the symptoms of secondary syphilis? Cullerier has furnished us with an example in the affirmative. Robert of Marseilles, one of the most ardent champions of the unity of the virus, has given us several conclusive examples to the same effect. But it is by no means a necessary consequence, and Ricord arrives at the following conclusion on the matter, viz.:—that the chancre with soft base occurring in syphilitic subjects, may transmit itself either as a hard chancre, or as a soft chancre, and that it is probable that the form under which this chancre reproduces itself, depends on the nature of its origin, that is to say, whether it was derived in the first instance from a hard or a soft sore.

It is these points of connection which lead one to believe that the two forms of primary sore are not manifestations of two different forms of virus, however different they may be as to their primary aspect, and as to the after progress of the disease. That they are sufficiently distinct as pathological conditions is admitted, I believe, by most persons. And it is surely a matter of vital importance, as to whether we have to deal with a local disease, merely requiring topical medication, or a constitutional malady, which some of the greatest authorities consider can never be entirely eradicated from the system. Nevertheless, in spite of well-marked distinctions, I think the weight of evidence goes to establish that the two varieties of chancre are manifestations of one and the same virus; that in some instances they are convertible, although in the great majority of cases they follow distinct courses. There is another circumstance also, which, I consider, establishes a close relation between the two chancres—one which fortunately cannot be put to the test of experience in this country—namely, that as yet no example of soft chancre has ever been found on the face or scalp. It would seem as if any syphilitic sore, whatever be its origin, were, of necessity, of the

infecting kind when situated in that region. M. Puche gives 28, and M. Ricord 26 examples, in which chancres situated on the cephalic region, whether externally, or on the tongue, lips, nostrils, always evinced an infectious nature, and were of the indurated variety. In the course of last year, M. Founder published a pamphlet on the subject of cephalic chancre, in which he records 120 cases collected at the hospitals of Midi and St. Lazare, in which he states, that in only two or three instances were the sores in this region unfol-
lowed by the usual sequelæ of the hard infecting chancre, and that in these two or three instances there was a considerable amount of doubt as to the true nature of the affection. This is a very important fact in the history of syphilis, and is an additional circumstance in favour of the unity of the syphilitic virus. Moreover, if the two forms of chancre were proved to belong to two distinct pathological species, it would establish nothing contrary to the unity of the true syphilitic poison. It would merely prove that in addition to the syphilitic poison, there was another affection commencing in a similar manner, with a sore, secreting virulent pus, but unlike syphilis, exercising no after effect on the economy.

I do not consider myself justified to judge on this matter, but I have ventured to lay the subject before the notice of the Society, in order that the individual experience of the members might be brought to bear *pro* and *con* on the subject.

TWENTY-FIRST MEETING.

March 31st, 1860.

The President in the Chair.

Dr. HARKIN introduced a child six days old, in whom the cerebrum was very imperfectly developed. The cranial bones were fully formed, the scalp loose, and the pupils contracted to the finest points. The child in other respects seemed healthy.

Case of Neuroma.

Surgeon BROWNE exhibited a neuroma which he had dissected out of a stump of the arm a few days previously.

The man from whose arm the growth was taken had, in Nov. last, his hand crushed by machinery, necessitating amputation of the forearm; this was done by Dr. Murney; disease of the bones, however, ensued, and the arm was again amputated about the middle. The case had been brought under the notice of the Society¹ early in the Session, by Dr. Murney. When the stump had healed up, acute irritation and periosteal inflammation set up, leading to the fear that it would be necessary to remove the limb at the shoul-

¹ [Occasion not identified.]

der joint. After some active treatment, however, the inflammation was subdued, and the part healed up entirely, save at one point, where a ligature was firmly held, and touching which gave intense suffering. At length, after repeated efforts, the ligature came away, the wound healed up, and the man was discharged for change of air, as his general health had declined considerably. He remained out of hospital for four or five weeks, but did not improve, as he latterly suffered constant irritation of the stump, and neuralgia of almost the entire system. On readmission, it was found that a neuroma had formed, and from which all his suffering proceeded. This growth was firmly attached to the inner portion of the cicatrix, in connexion with the bone.

“This,” Mr. BROWNE then said, “I dissected carefully out, dividing all the nerves I could discern in connexion with it, and divided the nerves some inch and half above the neuroma; in this dissection the brachial artery and a smaller vessel were divided and ligatured. My friend and colleague, Dr. Murney, examined the removed structure, and found the growth contained the extremities of the median, ulnar, and internal cutaneous nerves. The ulnar exhibited principally the congested and inflamed condition usually observed in this painful affection. Of course there is not any certainty that the disease will not return. At present, however, while there is pain and inflammation in the part, the general neuralgia has almost subsided. The patient I shall now treat by the exhibition of the preparations of iron, quina, and valerian, with a view of improving the health, and acting specially on the nervous system. Of course change of air will be advised.”

Dr. CORRY presented the Society with a drawing copied from one which accompanied the history of a case of Molluscum, furnished by Dr. Babington, of Derry, on the 5th Nov. last. The thanks of the meeting were conveyed to Dr. Corry for his contribution to the Museum.

TWENTY-SECOND MEETING.

April 7th, 1860.

The President in the Chair.

Dr. PIRRIE exhibited a foetus, with extra-cranial development of cerebrum.

Case of Senile Gangrene.

Surgeon BROWNE exhibited the morbid parts in, and read a case of, Senile Gangrene.

The patient, J. M'C, aged 67, a native of Whitehouse, was admitted into the Belfast General Hospital on the 12th of March, labouring under an attack of *gangrene senilis* of the leg and foot. The history of the

patient may be briefly stated. He had been an agricultural labourer all his life; had worked very hard; had been frequently exposed to great hardship and vicissitudes of weather; he had always lived temperately, and had reared a family of several children. Up till six weeks before admission to hospital, he had enjoyed excellent health, and had followed his calling every day. At the time specified, he began to have an uneasy burning sensation about the toes and heel of the left foot, with a pain and stiffness in walking. For three weeks he continued to work in the fields, the pain, however, increasing. About that period, he first saw discoloration of the toes, and he observed a coldness and numbness in the part. He was then compelled to take to his bed, the discoloration and coldness gradually creeping up the leg.

On the day of his admission to hospital, he presented the following signs and symptoms. From the left knee to the toes the part was quite cold and insensible; the upper part a deep olive colour, and flaccid to the touch; the lower portion and the foot quite black, and harder than natural. Above the knee there was an irregular line of demarcation, the part being dusky red and exceedingly painful; along the thigh, and upon the abdomen, the superficial veins were of a deep chocolate colour, and highly congested; the skin was covered with a free perspiration, and was all over of a dusky hue; the tongue was thickly coated with sordes; he had great thirst and oppression in breathing, and was very restless; the pulse was very irregular, weak, and about 110 beats in the minute. On examining the heart with the stethoscope, it was found to be weak and laboured in its action, an intermission, or rather a flutter, taking place about every four or five beats; no *bruit* could be detected; sugar in quantity was found in the urine. The femoral and external iliac arteries of the left limb were quite obliterated; the vessels of right limb pulsated throughout. This state of matters continued increasing, the thigh became greatly swollen and discolored, and the superficial veins all over the body became congested, and a most offensive odour escaped from the gangrened limb. For a few days before his death, the pulsation ceased in both radial arteries, and in the brachial artery of the right side; but on the 5th of April, the day before he died, pulsation, warmth, and colour were restored to both arms.

The post-mortem examination showed the heart to be hypertrophied in its left ventricle, with some fatty degeneration. The mitral valve was quite healthy, but the aortic semi-lunars were incompetent. The ascending aorta was considerably dilated, and covered with patches of atheroma, while the entire of that vessel, as well as the iliac arteries, were greatly inflamed. In the left common iliac there was a firmly-organised fibrinous clot; the vessels also arising from the arch of the aorta partook of the arteritis which

prevailed in the main trunk. The iliac veins and ascending *vena cava* were also inflamed, while in the latter, for several inches there was a fibrinous deposit or clot, firmly adherent to the lining membrane of the vein.

Surgeon BROWNE directed attention to the similarity of the case before the Society to one he had related in the November number of the *Dublin Journal of Medical Science*, and to be found among the *Transactions of the Belfast Medical Society*, for 1859,¹ and which he had given in full detail. Both cases illustrate the pathology of senile gangrene, as demonstrated by the Baron Dupuytren, namely, inflammation of the arterial system in some of its parts, and also of the veins; this inflammation, no matter how provoked, causing occlusion of the vessels, and consequent gangrene in the parts which they should supply with blood.

Dr. DRENNAN exhibited the larynx and lungs of a man whose symptoms previous to death were aphonia, cough, and great debility. The condition of the parts did not explain the cause of the aphonia, and though the lungs exhibited numerous isolated diseased spots, their condition was deemed insufficient to account for death.

447 Notice of the Twenty-Third Meeting in the Seventh Session.

Office-Bearers

President—Professor Reid.

Ex-President—Surgeon Browne, R.N.

Vice-Presidents

Dr. Murney.	Professor Gordon.
Dr. Reade.	Dr. Babington, Derry.
Surgeon Ferris, Larne.	

Council

Dr. Drennan,	Dr. Pirrie.
Dr. Dill.	Surgeon Johnston.
Dr. Patterson.	Dr. Heeney.

Treasurer—Dr. Halliday.

Secretaries.

Dr. Wales.	Dr. Cuming.
------------	-------------

The Twenty-Third Meeting of the Society this Session will take place in the Museum of the General Hospital, on Saturday, April 14, at Three o'clock.

BUSINESS.

The President will exhibit "Recent Parts illustrative of Morbid Appearances in Typhoid Fever."

Professor Gordon will exhibit—"Specimen of Scrofulous Disease of Shaft of Femur;" and make observations on—"Amputation at and in the neighbourhood of the Hip-Joint."

¹ [See page 225.]

Surgeon Johnston will read "Case of Empyema, with Post Mortem."

Dr. William Aickin will read "Notes of rapidly fatal Case of Diphtheria."

The Subscription—increased so as to enable the Council to forward the Transactions, as published, to every Member—being 12s 6d. to Town, and 7s. 6d. to Country Members, will be received by the Treasurer, at this Meeting.

Members desiring to forward Cases and Observations to be brought under notice of the Society, or to propose Candidates for Membership, will please communicate with the Secretaries, at least Three clear days before the day of Meeting.

Members of the Society have the privilege of forwarding Morbid Specimens, for examination by the Chemical and Microscopical Committee, and of receiving reports on their nature.

The Museum of the Society is open to all Members, between Two and Three o'clock on each day of Meeting.

JAMES CUMING, M.D.,
GEORGE F. WALES, M.B.,
Hon. Secs,

General Hospital, April 12, 1860.

TWENTY-THIRD MEETING.

April 14th, 1860.

The President in the Chair.

Dr. MOORE introduced a coloured woman, the greater part of whose right upper maxilla he had removed some time since. The absence of much apparent deformity, and the partial reproduction of the lost parts, were the points of interest in the case. He also exhibited a cast of the parts removed, which contrasted surprisingly with the slight deformity now discoverable.

Typhoid Fever.

The PRESIDENT made the following communication:—

I exhibit to-day two morbid specimens, of much interest in connection with the pathological changes occurring during "*typhoid fever*." It is only occasionally that such cases occur under circumstances that render them instructive and available for the elucidation of disputed points in the etiology or symptomatology of that disease. I shall, however, at present only allude to such of these points as my cases appear capable of illustrating.

I may premise my observations on the patients to whom these specimens belonged, by stating, that in this town and neighbourhood there has prevailed, for some time past, and in greater frequency than our usual "maculated typhus," a fever bearing the charac-

teristics of the species to which the name of “typhoid” has been given.

Since the publication, in 1829, of Louis’ treatise on the typhoid fever of France, much discussion has taken place in this country as to whether typhoid fever existed also here as a separate species, capable of being recognised and distinguished from our own “*maculated typhus*.” Unfortunately, the discussions on the affirmative and negative sides of this question were, until very recently, couched in general terms by both parties, without any attempt at investigating the subject by the method adopted by Louis. Whilst, therefore, we are not unmindful of Dr. Stewart and other physicians, who had ascertained and asserted that typhoid and maculated typhus were different species, we must accord to Dr. Jenner, of London, the merit of having been the first who adopted fully the method of Louis in his investigations, and of having succeeded in convincing many, that both species may be found prevailing at the same time in this country, and with varying frequency in the same hospital;—that infection from one kind will not produce the other, and that they are capable of being recognised and distinguished at the bedside of the sick.

In my report of the epidemic fever that prevailed in this neighbourhood in the years 1847 and 1848, which appeared in the *Dublin Quarterly Journal of Medicine* in 1849, I had advanced similar views respecting there being a plurality of fever poisons in that epidemic. Two years afterwards, I had evidence to satisfy me that typhoid fever existed also here as a distinct species, with all the characteristics described by Louis; that it might be found in the same hospital with cases of maculated typhus, and I am now certain that I had previously classified many cases of it as “*synochus*.”

In opposition to those who assert, that the different fevers which they acknowledge they meet with are merely the result of the influence of age, peculiarity of constitution, season of the year, or epidemic constitution of the year, the holders of the doctrine of a plurality of fever poisons adduce, as one of their arguments, that infection from one kind will not produce fever of another kind, and that it is possible to be able to trace in innumerable instances, that the cases of one species have been infected by persons suffering under the same kind of fever.

Now this is one point upon which I believe that the histories of my patients may be said to be instructive.

For some months past typhoid fever has prevailed in a village in this neighbourhood, and, through the kindness of a medical friend, I have been able to ascertain that both patients were, from periods varying from one to five days, in the house of his patients there who were ill with typhoid fever; whilst from another medical friend, who visited them when they took ill on their return to town, and whose official

position keeps him cognisant of the diseases prevailing where they resided, I have ascertained that there were no other cases of fever in their house, or in the neighbourhood of their residence.

Having thus traced them to have been within the sphere of typhoid infection, I next proceed to state the histories of their illness, and I shall commence with that of the girl who died first, premising that they were both aged about 18. This girl could give no history of her illness, being unable to speak when first seen, and, therefore, the account of it had to be obtained from her sister and others, who, however, agreed in all important particulars.

She visited the infected house on the 26th February, slept there at night, and returned to town the next day; continuing to work till mid-day of the 29th. Between these dates, it has been ascertained that she had frequent rigors, with intense headache, and alternate pallor and flushing of face. Diarrhoea also existed, as the floor of her room was in many parts covered with intestinal discharges. Her sister (whose intelligence was perfect) stated that the bowels had been very loose from the commencement, and that she had a rigor on the 27th. The existence of vomiting could not be ascertained. From the 1st of March her sister could not understand what she said, and in this state she was seen by her town attendant at his first visit, on the 4th, who directed her removal to hospital, which she did not reach till the evening of the 5th. She was then very cold and trembling, with a feeble pulse; her right eye much injected, the right pupil contracted, the other dilated, and still unable to speak. The appropriate treatment for the relief of the head symptoms was adopted, and she was reported, at my visit in the morning, to have improved in appearance during the night. I could not, however, count her pulse with accuracy, owing to the great subsultus, nor could she speak or protrude her tongue, although she appeared to understand what was said to her. The pupils were then both dilated, and the eyes injected. The bowels had become quiet. No improvement took place during the day, and she died before midnight of the 6th.

On post-mortem examination, the membranes of the brain appeared to be minutely injected with blood, entirely free from opacity in any part, and without any serous effusion. The substance of the brain, on being sliced, presented numerous dotted points, but there was no effusion into the ventricles. The lungs were both healthy.

No evidence of disease was found in the small intestine, until within a foot of the cæcum, when the mucous membrane became intensely injected. Peyer’s patches were now found swollen, red, and elevated above the surface, and this became more manifest as the cæcum was approached; six of them were found, (as may be seen in the specimen,) in a state of ulcera-

tion. There were no ulcers in the cæcum or colon, but about four inches from the commencement of the latter a brightly-injected patch of some inches was found. The mesenteric glands were enlarged to the size of filberts, and of a bright red colour.

This preparation, having been kept in spirits for some weeks, has become shrunken and much paler, and the non-ulcerated patches less raised than they were at first. Even the ulcerated patches have contracted fully one-half, so that the specimen has now less the appearance of acute disease than it had on removal.

Such was the state of the morbid parts on the ninth day, after she had spent a portion of a day and night in a house in which typhoid fever prevailed; and on the *eighth day* after she had experienced the initiatory rigor and other symptoms of her own illness.

And here I have to mention one of those disturbing elements that so often interferes with the accuracy of our conclusions in the investigation of disease. Had there been no possibility of her receiving infection, except during her visit on the 26th, we could have said, that the period of incubation in typhoid fever might be only 24 hours; but, it unfortunately happened, that the sister, whose history I have next to notice, had spent a portion of the day of the 19th February in the infected house, and as we admit that the infection of maculated typhus may be carried by the clothing of a healthy person going from an infected to a healthy house, if we extend the same law to typhoid fever, we must admit the possibility of her having imbibed the infection off her sister's clothing during the night of the 19th, which she spent with her in town, this sister having returned to the country the next morning. This would extend the period of incubation to eight days. I am not, however, disposed to adopt this latter view.

In addition to our being able to trace this case to have originated in infection from a typhoid patient, there are several other interesting circumstances connected with it.

1. Her death, within eight days after the initiatory rigor had taken place, and the existence already of ulceration in the ilium. Louis records only three cases of death so early as this, and it is somewhat remarkable, that the cerebral symptoms, such as the intense headache, the state of the pupils, the indistinct articulation, and latterly the taciturnity, and also the state in which the post mortem examination found the brain and the ilium, were, with a few trivial variations, precisely similar in his cases to what were present during life, and now exhibited as found after death in this case.

2. I believe that I am justified in ascribing the early death in this case to a destruction of nervous power from the circulation of the fever poison through the brain. We know that in small-pox, scarlatina, and

maculated typhus, cases occur occasionally, in which the nervous system is destroyed at once by the poisons of these diseases, and that the patient dies before their usual symptoms have had time to develop themselves.

3. The case is also instructive, as showing how early in the illness ulceration may take place, and that the disease is always farther advanced in the vicinity of the cæcum than in the direction of the duodenum. It also shows that the mesenteric glands are involved from the commencement of the fever, and not, as has been said by some, from irritation produced by extensive ulceration in the intestines.

I have next to notice the history of the second girl.

She, as I have already stated, visited the infected house on the 19th Feb., coming into town in the evening, and returned to attend the sick the next day, remaining with them till the 25th. Her intelligence, when seen, was unimpaired, and she stated that she was in perfect health on the 29th, that she had rigor and headache on the 1st March, and, although unwell, struggled on at her work till midday on the 3rd, when she was obliged to give up, and, as there was no one to look after her or her sister, they were sent into hospital on the 5th.

On the morning of the 6th her pulse was 114, her tongue red at the tip, furred, and moist in the centre; her bowels had been loose from the commencement, but the evacuations were free from blood. Her abdomen was full, and there was pain in the region of ilium. She had slight vertigo, but the headache had ceased; there was no noise in her ears, and the eyes were bright. A few red papulæ were found on the back of the chest, removeable by pressure. There was no cough, but there was present a symptom which I have observed to be of serious import, namely, a jerking or rather sobbing kind of inspiration.

I shall not occupy your time with a detail of the symptoms as they were daily entered in the case book, but shall only mention the gradually increasing intensity of them all till her death on the 25th of March, the 25th day after she had suffered from rigor and headache; and, it will be observed, that the day of the month answers also for the day of her disease, as her illness began with rigor on the 1st. On the day after her admission the pulse had risen to 132, and was found only once again so low as 120, having on two occasions reached 140. On the 6th of March the tongue was dry at the tip, and this state soon became general over it. On the 12th it was protruded with difficulty, and the voice became tremulous on the 18th, with indistinct articulation on the 20th. On the 19th there was tremor and subsultus; and on the 21st these involved almost every muscle of the body. Only once did she complain of headache; and her eye remained clear and bright till within a few days of her death. From about the 20th she was much disposed to

sleep, and there was occasional quiet delirium. The bowels acted two, four, six, or sometimes eight times daily, through all her illness; the abdomen was tympanitic, and remained full, whilst it was never free from tenderness on pressure over all the lower part of it. The evacuations from the bowels were generally very fluid and yellow, and never contained any blood. There appeared some cough on the 21st, with frothy expectoration, occasionally streaked with blood; it did not, however, increase in intensity. There was never any epistaxis.

On post-mortem examination, the lungs were found quite healthy.

Over several feet of the ilium, the elliptical or Peyer's patches were found red, raised, and ulcerated, as also a few of the solitary glands. These patches are evidently larger, and the disease in a more advanced stage, in the immediate vicinity of the cæcum. Two ulcers were found in the cæcum, and two on the commencement of the ascending colon. The mesenteric glands were found enlarged and much injected with blood, but not so swollen as in the other case. It is not without interest to observe how closely the morbid appearances found in this patient tally with several of Louis' cases who died about the twenty-fifth day of their illness. The brain was not examined. The immersion in spirits of the morbid parts since the 26th, has rendered them paler and contracted, and thus diminished the appearance of active and acute disease which they presented on their removal. I was constrained to do this, by feeling that I could not present their cases so instructively before you, until I had ascertained the nature of the disease from which they appeared to have imbibed infection; and for the trouble taken by my medical friends in obtaining information for me on this point, I feel very grateful.

Surgeon JOHNSTON read the following

CASE OF EMPYEMA.

During the summer of 1856, the subject of these remarks went to Newcastle for a holiday; when there he caught cold, and was seen and treated by Dr. Rea, who was also there at that time. He returned to Belfast in the beginning of September, when he first came under my notice. At this time, he looked very ill, had fever of the hectic type, suffered from dyspnoea and cough. On examination, I found evidence of disease in the upper portion of the left lung. There was crepitation, the expiratory murmur was unusually loud, and there was slight comparative dulness. The heart was in its normal position, and there was a *bruit* heard over its apex. Connecting the local and constitutional signs and symptoms, I was led to fear that his disease was of a tubercular character. Dr. Seaton Reid also saw him, and after repeated examinations, was of opinion that there were evidences of diseased action in the upper portion of left lung. He remained in town

during the winter of 1856, and until the summer of 1857. During this period, he continued in delicate health, suffered from exhausting night perspirations, had an attack of diarrhoea, and was quite unable to continue his duties as a clergyman. About July he went to the country, and whilst there he was laid up with what his friends considered an attack of fever, but which attack was ushered in with a severe shiver, and acute pain in his left side. Finding that he only partially recovered, and that his health continued to decline, he went to Dublin in October, 1857, and placed himself under Dr. Stokes's care. Dr. S. now discovered that he had extensive pleuritic effusion into the left side, the heart being completely displaced to the right. Dr. S. prescribed a prolonged course of iodine taken internally, and applied externally. He also administered the infusion of digitalis for a few days, but with great caution and constant watching.

Dr. Stokes took a great interest in his case: and here I cannot help gratefully acknowledging his uniform kindness and generosity to him,—I believe, only in keeping with his usual benevolence. Finding that the effusion continued, and that its amount was uninfluenced by the remedies administered, that the side was distended, and that the fluid was rather increasing than diminishing, he entertained the idea of tapping the chest. With this view Dr. S. called in Mr. Adams; on consulting, however, and hearing somewhat more of his previous history, and of his illness here in 1856, they determined not to interfere. He passed the winter of 1857 and spring of 1858 in Rostrevor. Writing from Rostrevor in December 1857, he thus describes his own feelings, position, and appearance, "It has pleased God to lay me aside as a useless vessel, a broken trumpet, a bruised reed. I have long felt as one carrying his coffin under his arm, unseen by any but himself."

He returned to Belfast in the summer of 1858, and I now for the first time had an opportunity of examining him since he left Belfast in 1857, and of course since the effusion had taken place in the left pleural cavity.

He presented an emaciated anæmic appearance. His pulse was seldom above 84. He had no hectic. The digestive functions were but slightly impaired. He slept comfortably, lying diagonally on the diseased side. He had a dry cough, and except when hurried, complained very little of any respiratory distress. I should say that the ratio of the respiration to the pulse was but slightly, if at all disturbed. His voice was weak; he complained very little of any local pain. The left side was visibly enlarged, and its movements restricted as compared with the right. The intercostal spaces were dilated and bulging.

The mediastinum was displaced; the left hypochondriac region was filled up; there was complete dulness all over the left side, absence of the respira-

tory murmur, except at the vertebral column behind, where respiration of a bronchial, blowing character could be heard. Vocal vibration was abolished. The heart was felt beating to the right of the sternum, beyond the cartilage of the fifth rib. And here I must advert to a symptom, in the observation of which Dr. Stokes took a considerable interest, viz., a distinct pulsating movement conveyed to the empyema from the heart, and manifest in the left cardiac region, so as at first to lead you to believe that there was two centres of pulsation.

This curious phenomenon may exist in various degrees, and is adverted to by Dr. Stokes p. 607 in his work on Diseases of the Heart. Walsh also, in his treatise on chest diseases, has described a pulsating variety of empyema, and narrated cases in illustration. The right lung was healthy, the respiration loud and puerile. From this period up till his death he continued under my observation. In the spring of the year 1859 he had a sharp attack of bronchitis in the right lung, which confined him for some weeks to the house, and caused him considerable uneasiness. If I except this illness, I might say that, up to within ten days of his death, he was able, with care, to follow to a very great extent his ordinary pursuits. He visited his friends, and enjoyed their cordial hospitality—administered to the poor and the sick. He presided at public meetings, and frequently preached and conducted the religious exercises of his charge. All this will appear the more wonderful if we contemplate “the coffin he was carrying about under his arm.”

Ten days prior to his death he presided at an evening meeting in one of the churches in town. The following day he felt ill, and was seen by Dr. Rea, who, with Dr. S. Reid and myself, attended him until his death. He had a shiver, and complained of acute pain in his right side, near the base of lung, where, on examination, we found evidence of localised pleuritis. There was also considerable diffused bronchitis. His pulse quickened; his breathing became somewhat distressed; he complained of a feeling of distension and uneasiness in the left side. He lost his appetite; stomach refused to retain food; he gradually sank, and without much pain or distress, died on the evening of Tuesday, March 14th, aged 36 years. His death was rather from asthenia than dyspnoea.

Dr. Murney kindly conducted the post mortem 30 hours after death, in presence of Dr. S. Reid, Surgeon Rea, and myself. The left hypochondriac region was completely filled up by a prominent fluctuating tumour. On opening the abdominal cavity, we found the left pleura covered by the left leaf of the diaphragm, projecting into and completely filling up the left hypochondriac region, even extending into left iliac, displacing the left lobe of the liver downwards, and to the right, and pushing the stomach completely into the umbilical region. The liver was not larger than

usual. It presented a mottled or speckled appearance. There were no evidences of any tubercular deposits in the abdominal cavity. On opening the left pleural cavity, we found it completely filled with pus, which, on careful measurement with a graduated measure, was found to amount to above the almost incredible quantity of two gallons. A small elongated, flattened mass, about four inches in length, and two in breadth, was found at the upper and back part of the cavity. This was all that remained of the lung, its surface covered with a false membrane fully one-sixth of an inch in thickness, and completely tied down by firm bands of adhesions. On making a section, we discovered purulent deposits in its substance.

The small bronchial tubes were very manifest, and on careful examination of the compressed mass, we found traces of an old-standing cavity, viz., a defined space, lined with a thin membrane, with the extremities of small bronchial tubes opening on its surface, but no evidence of its having been a tubercular cavity, nor could tubercle be discovered elsewhere in the compressed lung. The right lung was considerably encroached on by the fluid contents of left pleura, as well as by the heart. It was rather hypertrophied, somewhat emphysematous, but perfectly free from any tubercular deposit. The pleural covering of the base was coated with recent lymph, and there was about 10 or 12 ounces of serous effusion into the right pleural cavity. The heart was small and flabby; its apex was opposite the right rib one inch beyond its junction with its cartilage.

The retrospect of this case suggests two or three points of interest. First, the amount of purulent effusion found, is, I believe, almost unparalleled. Dr. Watson mentions a case in which Sir P. Crampton drew off the “almost incredible” quantity of fourteen pints—here we had over seventeen. No doubt the fluid had increased during the patient’s final illness, but even making some allowance for such increase, does it not strike one with surprise, that for the last two years and a-half he was capable of such physical and mental efforts. Not more than two months since, I was myself present at a large public meeting at which he presided, and made a very happy and pleasing speech in honour of a much esteemed friend, who had been acting for some time as his assistant. We have certainly here manifest proof of great strength and composure of mind, as well as of the adapting and sustaining power of nature. But another point of interest suggests itself—was the effused fluid from the first of a purulent character; or was it sero-albuminous?—the sac afterwards taking on a pyogenic character, and the watery constituents of the primary effusion undergoing absorption. I am rather inclined to think, that the chronic supervened on the acute attack—and that the products of the diseased action changed. The absence of any well-marked hectic, for a period of

above two years, is worthy of notice, and was calculated to mislead one in regard to the nature of the contents of pleural sac. He had no night perspirations of any moment after the spring of 1857, and his pulse was seldom or ever above 84. But the most important inquiry in connection with this case is, how far it would have been suitable for the operation of paracentesis, and whether such operation would have proved effectual, in restoring or prolonging the life of our patient?

In Ireland we are much behind our French and English brethren in adopting this operation. "A procedure," says Walsh, "which, no matter how divided opinion may be respecting its general feasibility, has assuredly been sufficiently often either completely successful, or productive of marked improvement, to justify its being numbered among the valuable gifts of surgery."

Dr. Watson lays it down as a rule, that whenever (no matter how we ascertain the fact) the effused liquid consists of pus, it should be let out. And Laennec advocates the performance of the operation in tuberculous patients, because even in them it may be the means of somewhat prolonging life. Out of sixteen cases of empyema, in which paracentesis was performed, Dr. T. Davis reports twelve recoveries.

The necessity of operating in the case I have detailed was for a time a subject of serious consideration with Dr. Stokes; and now, in reviewing the case, with the light thrown upon it by the postmortem, I am inclined to conclude that, failing the remedies administered to promote the absorption of the fluid, it would, (when the adhesions were recent,) have been a fair case for the operation. No doubt, we are now in possession of knowledge which at that time it was impossible to arrive at, and in regard to which the weight of evidence leads one to arrive at a different conclusion from that to which the results of the post-mortem conduct. I refer, of course, to the prior existence of tubercular disease of the left lung.

Whether it is possible that the pressure of the fluid may have expelled any tubercular matter from the cavity, the remains of which we have shown you, may admit of some doubt; but I believe that the weight of evidence is in favour of the view, that the attack at the apex of his left lung, for which I attended him eight months prior to the effusion, was of an asthenic inflammatory character, terminating in abscess, but not tubercular.

The absence of all trace of tubercle, either in the healthy lung, or in the abdominal cavity, and of any cretaceous particles in the remnant of the left lung, lead one to conclude that we had not a tubercular patient to deal with. And if we add to this the power which his constitution showed in bearing up so long and so well under such an amount of disease, we will feel more impressed with the opinion that, at an early

period, paracentesis might have possibly been attended with success. No doubt any interference of late would have been very injudicious, the lung being so firmly compressed and bound down by such thick adhesions, as to forbid any hope of its expansion—a very material condition to a successful issue.

In support of the view I have here taken, I cannot help adverting to the case of M'Donnell, the news-boy, whom I presented to the notice of the Society some time ago. In this case, nature performed the operation under very unpromising circumstances, and yet, notwithstanding that he has been constantly exposed during the past inclement winter, his health continues to improve, the discharge from the fistulous openings has almost ceased, and I believe that there is now every prospect of a permanent recovery. On the other hand, however, weighty reasons may be adduced for not interfering in the case now reported:—The absence of hectic, or any urgent symptoms of respiratory oppression, and the fear that the entrance of air might have caused putrefactive decomposition, with accompanying constitutional disturbance, under which our patient might have succumbed at a much earlier date.

Council Special Meeting Monday 16th April.

Present, the President, Drs. Dill, Halliday, Wales, Cuming, Patterson, Browne.

List of members was prepared.

Moved by Mr. Browne seconded by Dr. Patterson "That casts to be taken of the morbid parts presented by the President at last meeting."

Accounts were passed of advancements in medical registration.

Council Wednesday [undated].

President, Dr. Cuming.

Circular was prepared.

Passed 10/6 to J. McCann for materials for casts.

TWENTY-FOURTH MEETING.

April 21st, 1860.

The President in the Chair.

Aneurism of Aorta, Opposite the Cæliac Axis.

The PRESIDENT said:—

I exhibit to-day some morbid structures, removed from the body of a patient who died from the bursting of an aneurism.

His age was 40. He stated that his employment had required him for years past to lift heavy weights; but that he had never felt any sudden pain, or received any injury till about one year and a half ago, when, on stooping to roll a barrel, he felt a severe pain across "the small of his back."

Having a considerate employer, he was changed by him to a less laborious kind of work, which enabled him to continue constantly on duty till one month ago.

Since he first felt pain, he has always had difficulty in stooping, and required help to put on his shoes in the morning. The pain was always increased in the evening, and during the early part of the night, till he became warm in bed. It was renewed by cold, and became less severe when he was engaged at work. It was so much relieved by the hot weather during two months of last summer, that he thought he had got rid of it entirely.

The pain was of a constant boring kind across the spine, and in both haunch bones, "as if his loins were in a vice," but this feeling did not extend to the front of the abdomen.

He had never had any shooting pains or cramps in the abdomen or legs. He is unable to flex the right leg up towards the trunk as perfectly as the left, and when he stands it is advanced forward in much the same position as in a person with hip-joint disease. There is no œdema of the limbs, but when he stands up the veins in both legs become suddenly and unusually prominent.

He has never had any difficulty in swallowing, or any hiccup or vomiting. His bowels only require medicine occasionally; they act without pain, and the evacuations have never contained blood. He has no difficulty in passing urine, which has never been bloody; its specific gravity is 1,635, neither saccharine nor albuminous. He has never had any pain in the testicles.

He lies best on his right side, less easily on his back, and worst on his left side.

His countenance is pale and sallow, and he has been emaciating rapidly during the last four or five weeks.

He has never had any cough or dyspnoea, or expectorated blood.

About two weeks ago, he observed "a beating pain" in his back, and some numbness in right loin, extending about four inches forward.

A pulsating, slightly elevated tumour is to be felt and seen between the 11th, 10th, and perhaps 9th intercostal spaces, on the right side, about one or two inches from the vertebræ, but none on the left. Pulsation is also seen extending forwards round the right loin, just below the margin of the ribs. The slightest pressure over this locality gives acute pain, but there is no pain on left of the spine.

A slight pulsation is to be seen and felt in the mesial line between the ensiform cartilage and to within an inch or two of the umbilicus.

A double sound, almost identical with that of the heart, is heard quite distinctly over the tumour and the spine, and to the left of the latter; but there is no

murmur. This sound only continued for about four days after he was first seen by me.

A single murmur is heard about half an inch below the ensiform cartilage, and over a triangular space, bounded by the margins of the ribs and a line crossing about an inch above the umbilicus. This murmur is best heard on light pressure with the stethoscope, and disappears entirely as we approach the region of the heart. It is but doubtfully heard when he stands erect, and is not equally distinct on every day.

No murmur is heard in the aorta, at, or below the umbilicus.

The right pupil is markedly smaller than the left, but capable of being dilated by belladonna to the same size as the left; again resuming its contracted state as soon as the effects of the belladonna passed off.

There is a distinctly increased pulsation in the right side of the neck, and in behind the sterno-clavicular articulation, which is very marked when compared with the left side.

A double sound is heard continuously from the top of the sternum, and its margin on both sides, till the heart is reached. No murmur is heard at any portion of the chest or cardiac region, till the stethoscope again reaches the epigastrium. No heaving pulsation is to be seen or felt over the front of the chest or cardiac region in any position.

Such is a statement of the positive and negative symptoms, presented by this patient when I first saw him.

The only change in them for several days, was his feeling more pain in the left hip, and some pain for the first time in his left shoulder, and in attempting to raise the arm of that side; A "smarting pain" was also felt in the right loin, where the sensation of numbness existed; this continued till the morning of the day on which he died. At two o'clock in the morning of that day, he awoke with a "tickling in his throat," coughed once or twice, and brought up two mouthfuls of blood, he was certain he coughed it up, and did not vomit it. Shortly afterwards, he experienced a very severe pain below the right nipple, which compelled him to turn on his left side, being quite unable to lie on his back.

At my visit in the morning, I found he had passed urine; he had no cramps in his legs, or hiccup, or vomiting; he had felt very faintish when up to get his bed made.

The pulsation was less in the right side of the neck, he had no noise in his ears, and there was no change in the tumour in the back. His pulse was 114, with little strength, and his skin was hot and dry. At 7, P. M., the pain in the right side of his chest became so severe that he could lie no longer on the left side, and he was gently turned over on the right; he immediately coughed up two or three ounces of frothy blood,

became pale, with profuse perspiration all over the body, and gradually cold. The breathing never became hurried; and some rale that appeared after he had brought up the blood, soon ceased. He became gradually weaker, and died quietly, and without any convulsion, at half-past nine, within three weeks after he had first observed the “beating pain,” and in about six after he had been obliged to give up working.

I had no difficulty in arriving at the conclusion, when I first saw this patient, that he was the subject of aneurism; and I considered that the locality of it was the very lowest portion of the thoracic aorta.

I was led to this conclusion respecting its seat by the distinct pulsation that was felt and seen between the two, if not three, lowest intercostal spaces on the right side, but more especially by the fact that he asserted that there was but one kind of pain, and an entire absence of the shooting or lancinating pain first noticed by Dr. Beatty, of Dublin, to be one of the most certain diagnostic symptoms of abdominal aneurism, when conjoined with the constant gnawing pain so very frequently present in all internal aneurisms. Nor was there any vomiting, or peculiar pain when the bowels acted, or indeed any symptom of disordered function of any organ below the diaphragm. In support of the opinion that there was no disease in the upper portion of the aorta, we had neither cough, nor dyspnoea, nor stridor, nor pain in or between the shoulders, nor diminished expansion of one lung, nor heaving pulsation of the upper portion of the chest; in fact there was not a single chest symptom except the pain and pulsation at its very base; and although Stokes, Bellingham, Walsh, and Sibson all mention that aneurism of the descending portion of the thoracic aorta almost invariably makes its way between the intercostal spaces on the left of the spine, still, from the absence of the symptoms discovered by Dr. Beatty to be peculiar to abdominal aneurism, as well as of those of the upper portions of the aorta, I felt justified in assigning to the aneurism the locality I have named.

Having been fortunate in obtaining a post mortem examination, the following is the state in which the various organs implicated were found.

On laying open the chest, nothing unnatural was found in the left side except a band several inches in length between the costal and pulmonary pleuræ. A considerable amount of serum flowed out from the right pleura; and at its back part were found several pounds of firm clots of blood, which had compressed and indented the upper portion of the right lung. The lower lobe of this lung was found adhering at one part to the aneurismal sac, and through the walls of the latter lower down a rent had taken place into the pleural cavity, through which the blood had escaped. The heart was healthy in structure and size—no disease of any kind was found at either of the orifices, or

in the structures of the valves. The arch of the aorta was not dilated; there were a few soft atheromatous patches in it. The innominate artery, when slit open and spread out, measured transversely $1\frac{1}{2}$ inch, and the right carotid appeared also a little dilated. This dilatation of the innominate and carotid would explain satisfactorily the increased pulsation that existed during life in the right side of the neck. With the exception of some atheromatous deposits, the calibre and coats of the aorta appeared normal until within an inch and half of the origin of the cœliac axis, where it became dilated to near double its natural size, and continued so for about an inch below it. From the back, or vertebral surface of this dilatation, two sacs, or perhaps a bilocular aneurism, were given off; that on the left side of the vertebræ was about half the size of a cricket ball, whilst that on the right was the size of a large cocoa nut, and had dissected its way between the diaphragm and the pleura, extending into the cavity of the chest fully six inches, and perpendicularly to almost the same extent, firmly attached to the sides of the bodies of the four last dorsal and two upper lumbar vertebræ, and in close contact with the ribs for several inches.

Over the anterior portion of this large sac, the upper or great splanchnic nerve can be seen stretched. The bodies of two or three of the vertebræ can be felt to be eroded. The origin of the right psoas magnus muscle was stretched by the lower portion of the aneurismal sac, which was no doubt the cause of the imperfect flexion of the thigh upon the trunk.

In addition to the rent into the cavity of the pleura, another had taken place into the lower lobe of the right lung, and had dissected the pleura from the lung for several inches in extent. To this rent we are no doubt justified in ascribing the occurrence of the hæmoptysis on the two occasions shortly before his death. This would appear to be a very rare symptom in aneurism of the aorta *opposite the cœliac axis*, as in 131 cases tabulated by Dr. Sibson, in his “Medical Anatomy,” hæmoptysis did not occur once.

I apprehend that the locality in which this aneurism extended is a very unusual one. I find no record in any of the books I have access to, of an aneurism separating the pleura from the diaphragm; and whilst the original opening was in that portion of the abdominal aorta that is behind the origin of the cœliac axis, still the aneurismal sac extended in a direction and produced symptoms that were exclusively thoracic in their seat, and unassociated with a single symptom that is considered to be characteristic of aneurism of the abdominal aorta.

There is just one other point of interest in connection with this case, to which I feel called on to refer. I allude to the undoubtedly contracted state of the right pupil. A contracted state of one pupil has been found to be of frequent occurrence in thoracic aneur-

ism, since the attention of the profession was directed towards it by Dr. W. T. Gairdner of Edinburgh, in 1856. So far as I am aware, the patients in whom it was observed had all suffered from aneurism or dilatation about the arch of the aorta, or a non-aneurismal tumour in the neck, in which cases it was considered to have been produced by pressure on the sympathetic, or on the anterior roots of the spinal nerves in the lower cervical or upper dorsal region, which are supposed to confer a motor power on the filaments of the sympathetic which join the 5th pair that supplies the dilating fibres of the iris.

It is clear, from the slight amount of dilatation of the innominate and healthy state of the aorta in this patient, that there was no possibility of any pressure being made at the cervical region in him; and we are therefore forced to inquire if the contracted state of the right pupil might not have been owing to the unavoidable pressure that must have been made on that portion of the sympathetic that forms the great splanchnic nerve, by its being stretched to such an extent over this large aneurism on the right of the vertebræ.

It is not without interest to notice how this man was able to continue in an occupation that required frequent changes in the position of the trunk of the body till within five or six weeks of his death, and that his disease, up till within a few weeks of its termination, had originated (so far as he had observed) but a single symptom, or at most two, namely, pain and an inability to stoop to put on his shoes.

Malformation of Sternum.

The PRESIDENT next introduced Herr Johann Heinrich Woytiz, a young man, who is the subject of a remarkable congenital depression of the lower third of the sternum and adjoining cartilages. By measurement, it was found that the sternum, at its greatest depression, approached to within about an inch and a-half of the vertebral column. Whether depending on this condition of the chest, or otherwise, the subject of this formation exhibited extreme mobility of the shoulder articulation. He was thus enabled to rotate and advance his *humeri* to such a degree as readily to bring their external condyles together. The Society deemed this malformation of sufficient anatomical interest, in relation to the existing healthy condition of the thoracic viscera, to authorize a cast of the thorax, which was accordingly secured, and has been added to the Pathological museum.

448 Notice of the Twenty-Fifth Meeting in the Seventh Session.

Office-Bearers

President—Professor Reid.

Ex-President—Surgeon Browne, R.N.

Vice-Presidents

Dr. Murney.

Professor Gordon.

Dr. Reade.

Dr. Babington, Derry.

Surgeon Ferris, Larne.

Council

Dr. Drennan,

Dr. Pirrie.

Dr. Dill.

Surgeon Johnston.

Dr. Patterson.

Dr. Heeney.

Treasurer—Dr. Halliday.

Dr. Wales.

Dr. Cuming.

The Twenty-Fifth Meeting of the Society this Session will take place in the Museum of the General Hospital, on Saturday, April 28, at Three o'clock.

BUSINESS.

Appointment of Auditors of Accounts.

Professor Gordon will exhibit—"Specimen of Scrofulous Disease of Shaft of Femur;" and make observations on—"Amputation at and in the neighbourhood of the Hip-Joint."

The Subscription—increased so as to enable the Council to forward the Transactions, as published, to every Member—being 12s 6d. to Town, and 7s. 6d. to Country Members, will be received by the Treasurer, at this Meeting.

Members desiring to forward Cases and Observations to be brought under notice of the Society, or to propose Candidates for Membership, will please communicate with the Secretaries, at least Three clear days before the day of Meeting.

Members of the Society have the privilege of forwarding Morbid Specimens, for examination by the Chemical and Microscopical Committee, and of receiving reports on their nature.

The Museum of the Society is open to all Members, between Two and Three o'clock on each day of Meeting.

Hon. Secs,

General Hospital, April 26, 1860.

441 To the Secretary

General Hospital
27th April 1860

Sir

Would you be so kind as to obtain for me certificates of attendance on the meetings of your society during the past and present sessions.

I am
your obedient servant
W. James Wilson
sen. sch. 2.C.B.
Resident Pupil, B.G.H.

Belfast Clinical and Pathological Society

Seventh Session: 1859–1860

President James Seaton Reid

TWENTY-FIFTH MEETING.

April 28th, 1860.

The President in the Chair.

Articular Injury.

Dr. MOORE introduced a person who had sustained an injury some time since, by which the ankle joint was laid open. By suitable treatment, Dr. M. was enabled to bring about the recovery of his patient, with the function of the articulation unimpaired. He considered the case a good example of conservative surgery in a most serious class of injuries.

Artificial Anus.

Surgeon JOHNSTON introduced an aged woman who had escaped the consequence of strangulated hernia by the spontaneous formation of an artificial anus in the left inguinal region. She experienced little inconvenience beyond that produced by a prolapsus of the gut at the artificial opening; to prevent which, she was obliged to resort to mechanical support.

Ballot paper from Council minute book.

JAMES CUMING, M.D.,
 GEORGE F. WALES, M.B.,
 Hon. Secs,

General Hospital, May 3, 1860.

Council Report of Council.

[This report is identical to that recorded in the transactions of the annual meeting which is reproduced below.]

TWENTY-SIXTH, OR ANNUAL MEETING.

May 5th, 1860.

The President in the Chair.

The business of this, the final meeting of the session, was entirely engrossed by the details of the Society's management and progress, comprising reports from the Council and Auditors, and the appointment of the Executive for the ensuing year.

REPORT OF COUNCIL.

"In bringing forward the report on the Session which is now closing, the Council has much satisfaction in congratulating the members of the Clinical and Pathological Society on its position and prospects.

The Society now includes within its ranks 100 members, of whom 45 are town members, 52 are country members, and 3 are honorary members, showing an increase of 6 upon the number of members in last Session, and of 4 upon Session 1857-58.

This augmentation of the Society's numbers, in itself highly satisfactory, becomes especially gratifying when viewed in connexion with the fact, that the annual payment for the Abstract of the Society's proceedings, which in former years was paid only by a limited number of members, has, during the present Session, been made compulsory on all.

This change, recommended by the Council, was adopted at a special meeting of the Society, held on the 24th of September, 1859, and the Council refer with pleasure to the fact, that an addition to the amount of subscription has been accompanied by an increase of the number of members as a significant evidence of the existing appreciation of the utility of the Society, and as an auspicious omen of its permanence and progress in the future.

Belfast Clinical and Pathological Society

Seventh Session: 1859–1860

President James Seaton Reid

During the Session 26 ordinary meetings have been held, at which a large number of communications of value and interest have been brought forward.

The Museum has been increased by specimens, casts, models, and drawings, and considerable progress has been made towards the completion of a catalogue of this valuable collection.

In conclusion, the Council has great satisfaction in being able to bear testimony to the undiminished interest which the members have exhibited in the progress and welfare of the Society, and to the unbroken harmony which has continued to characterize the meetings, as well as to the able and dignified manner in which the presidential duties have been discharged by Dr. Seaton Reid.”

Drs. Cuming and Wales, the Honorary Secretaries, having resigned, and their successors appointed, the proceedings were brought to a close by the thanks of the Society being conveyed severally to the retiring President, the retiring Secretaries, and the Treasurer.

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

BELFAST CLINICAL AND PATHOLOGICAL SOCIETY.

EIGHTH SESSION—1860-61.

437

May 7 1860

Dear Sir

Will you and Dr. McCormack be kind enough to call a meeting of the Council of the Belfast Clinical and Pathological Society at the hour of 7 P.M. Tuesday 8th May "to receive a report of Dr. Murney's reply respecting the office of President of the Society and to adopt such measures as the Council may in consequence deem necessary."

Very truly yours
J. Seaton Reid
ex-President

455 *Draft agenda dated May 7th 1860 for a meeting of Council and draft minutes of that meeting which was held on May 9th 1860.*

Session 1860 & 61

May 7th 1860

by letter N^o. —

The ex-President requested a meeting of Council to be called to receive a report of Dr. Murney's reply respecting the office of President of the Society to adopt such measures as the Council may in consequence deem necessary.

The following were summoned as members of Council the list not being completed. S. Reid, Drs. Patterson, Pirrie, Bryce, Babington, Dunlop, Graves, Johnston, Browne, Dill, Drennan, Corry, MaCormac and Aickin.

The meeting was held on May 9th 3 p.m. Present Drs. S. Reid, Browne, Drennan, Dill, Corry, MacCormac, Aickin.

Resolution 1. Proposed by Surgeon Browne, seconded by Dr. Pirrie. That in consequence of the non-acceptance of office of President by Drs. Murney and Reade to which they were successively elected the Secretaries are directed to issue new ballot papers for the election of a President for the current year. The names of the eligible candidates to be appended to the circular.

Resolution 2. Proposed by Dr. Drennan, seconded by Surgeon Browne. In compliance with the above Resolution, the following note be appended to the ballot papers.

N.B. Members are to observe that all ballot papers must be received by the Honorary Secretaries at the Hospital on or before Tuesday the 22nd inst. at 6 p.m.

Resolution 3. Proposed by Dr. Dill, seconded by Dr. Corry. That a second box with admissions valve be procured for the reception of the ballot papers. The

box to be in charge of the President and the box to remain at the General Hospital in care of the Secretaries. The box to be opened at the meeting of Council appointed for the counting of the ballot papers, the valve having been introduced previously at the hour specified by the Council as the latest for receiving them.

Mr. W. James Wilson, Sen. Sch. 2.C.B. Resident Pupil in Hospital was granted a certificate of attendance at the Society meetings during the past session.

There were 100 ballot papers printed and circulated on the 10th. initialled W.A.

Next Council meeting to be held Wednesday 23rd May at 3 P.M.

Council Meeting of Council May 12th 1860.

Summoned by order of the Ex-President.

Moved by Mr. Browne and seconded by Dr. Pirrie "That in consequence of the non-acceptance of the office of President by Drs. Reade and Murney fresh ballot papers be now issued to all the members for the purpose of electing a President for the ensuing year."

Moved by Mr. Browne seconded by Dr. Dill "That in order to guard against error in the reception of ballot papers, none be acknowledged that are not received by the Honorary Secretaries at the General Hospital on or before Tuesday the 22nd inst. at 6 P.M."

Moved by Dr. Drennan, seconded by Mr. Browne "That the preceding resolution be placed as an N.B. on the ballot paper, and also the names of the Vice-Presidents eligible for election—Drs. Ferguson, Gordon, Mr. M'Gee, Murney, Pirrie, T. Reade, Stewart."

Moved by Dr. S. Reid, seconded by Dr. Dill "That a ballot box be purchased for the reception of balloting papers" also "That a meeting of Council be summoned at 3 P.M. on Wednesday 23rd to examine the ballot papers."

438 *Handwritten note [see also 439]*

In consequence of the non-acceptance of the office of President by Drs. Reade and Murney, to which they were successively elected, we have been directed by the Council to issue new Ballot Papers for the election of a President for the current year.

439 *Printed ballot paper [see also 438]*

Sir

In consequence of the non-acceptance of the office of President by Drs. Reade and Murney, to which they were successively elected, we have been directed by the Council to issue new Ballot Papers for the election of a President for the current year.

The following is the list of those eligible for election:—

Professor Ferguson.
 Professor Gordon.
 Dr. W. Magee.
 Dr. Murney.
 Dr. Pirrie.
 Dr. Thomas Reade.
 Dr. Stewart.

President, _____

N.B.—Members are to observe that all Ballot Papers must be received by the Honorary Secretaries, at the Hospital, on or before Tuesday, the 22nd instant, at Six, p.m.

Signed;
 W. MAC CORMAC, M.A., M.D.,
 W. AICKIN, M.D.,
 Honorary Secretaries

General Hospital, Belfast
 May 9th, 1860

440 To the Secretaries

Dundalk
 11th May

Gentlemen

As it quite out of my power to attend the meetings of the Belfast Pathological Society it is not my intention to continue to be a Member. I need therefore not fill up the voting paper just received.

Your Obedient Servant
 E. J. Brunker
 M.D.

442 To the President &c.

Newtown Butler
 May 21, 1860

Sir

I beg again to bring under your notice my application for certificates of two seasons attendance on the Clinical and Pathological Society and hope to hear from you a favourable reply.

It has I understand been customary to grant them to students, and as I am looking for a public appointment such certificates would of course be of infinite service to me.

Please excuse this trouble.

I am Sir
 Yours respectfully
 John Thomas Moore
 M.R.C.S.Eng.

Council Meeting of Council May 23rd 1860 3 P.M.
 Counting of ballot papers.

Council summoned. S. Reid, Patterson, Pirrie, Bryce, Johnston, Browne, Dill, Drennan, Corry, Maccormac, Aickins.

Proposed by Dr. Patterson and seconded by Dr. Johnston that a Special Meeting of the former Council be summoned to make out a correct list of Vice-Presidents and Council for the current year.

The 54 ballot papers were destroyed by the President.

Members present. S. Reid, Johnston, Patterson, Maccormac, Bryce, Corry, Aickins.

Letter from Dr. Brunker, Dundalk, withdrawing his name as a member, and from Surgeon John Thos. Moore, Newtown Butler, applying for certificates for attendance at the Society's meetings for two sessions.

Surgeon Johnston received an order for two pounds sterling being the amount paid to _ German for a cast of his chest, and also for showing himself at the last meeting of the Society.

Double Council summoned for Saturday 26th. May 3 o'clock.

Dunlop. Johnston, Bryce, Pirrie, S. Reid, Patterson, Cuming, Murney, Drennan, Dill, Corry, Wales, Heeney, Maccormac, Gordan, T. Reade, Browne, Halliday.
 = Present.

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

444 Undated list of members of Council. With the exception of Dr. Murney as President, the names correspond with those who made up the Council in 1860–61.

The names written in a lighter ink are those who, in Item 445, gained the highest number of votes in the relevant section (President one name; Vice Presidents three names; Council six names).

[Names darker ink.]		[Names lighter ink.]
	President	
Murney		Thomas Reade
	Vice Presidents	
Patterson		Murney
Pirrie		Patterson
Bryce		Pirrie
	Country	
Babington		
Dunlop		
Graves		
	Council	
Johnston		Bryce
Browne		Johnston
Dill		Dill
Drennan		Drennan
Corry		Browne
Mulholland		Corry
	Secretaries	
Dr. MacCormac		
Dr. W. Aiken		
	Treasurer	
Dr. Halliday		

445 Undated spreadsheet with entire list of members, and records of votes cast for the various positions (President, Vice Presidents, Council, &c.) and the results.

COMPILER'S NOTE

In Item 445, Dr. Thomas Reade topped the list for President; Drs. Murney, Patterson and Pirrie for Vice Presidents (Resident); Drs. Babington, Dunlop and Graves for Vice President (Non-resident); and Drs. Bryce, Johnston, Dill, Drennan, Browne, and Corry for Council.

Item 445 must be the original record of voting and the list in lighter ink in Item 444 represents the results of that vote.

The list in darker ink in Item 444, must have been written after Dr. Reade refused to serve as President with the result that Dr. Murney's name was moved up to replace his.

Dr. Murney also refused to serve (Dr. J. Seaton Reid's letter, Item 437), and this led to the Council meetings (Items 455 and 456), the circular regarding a second vote for President (Items 438 and 439), and the election of Dr. Gordon as President for 1860 to 1861 (Item 443).

450 Report on a Pathological Specimen¹

Clinical and Pathological Society

General Hospital Belfast

May 26th 1860

R. B. McClelland Esq. M.D.

Dear Sir

The slice of Tumour you sent us for microscopic examination appears to be osseous and cartilaginous but there is no appearance of cells of a malignant growth.

The cartilage cells are of the simplest formation almost like fat cells.

The bone cells are not so well developed but you can find out traces by examining several sections.

We are Sir,

Your obedient servants

William Aickin M.D.

William MacCormack M.A. M.D.

Honorary Secretaries

P.S. Would you please let us know the size and general appearance of the tumour.

You might please mark out a detailed case if you think it of any peculiar interest and forward it to us.

Council Meeting of Council August 30th 1860, 3 P.M.

Present, Drs. Dill, Patterson, S. Reid, W. Aickin.

Moved by Dr. S. Reid, seconded by Dr. Patterson "That the Treasurer be authorized to pay the following accounts remaining due from the session 1859–60.

William McNeill, Corn Market, for ballot box. 15/-
Alexander Mayne, High Street, for printing and binding transactions.

Dr. Aickin, Secretary of Council, for stamps for circulars. 5/-"

OFFICERS FOR 1860–61.

PRESIDENT.—Professor Gordon, M.D.

EX-PRESIDENT.—Professor Reid, M.D.

VICE-PRESIDENTS.—(Town)—Dr. Patterson, Dr. Pirrie, Dr. Bryce. (Country)—Dr. Babington, Londonderry; Dr. Dunlop, Holywood; Dr. Graves, Cookstown.

COUNCIL—Surgeon Johnston, Surgeon Browne, R.N, Dr. Dill, Dr. Drennan, Dr. Corry, Dr. Mulholland.

TREASURER.—Dr. Halliday.

HON. SECRETARIES.—(General) Dr. W. Mac Cormac, (Council) Dr. W. Aickin.

¹ [Perhaps the earliest extant Belfast pathological report.]

LAWS OF

THE BELFAST CLINICAL & PATHOLOGICAL SOCIETY.

I. NAME AND OBJECTS.—The Society shall be called “The Belfast Clinical and Pathological Society,” whose objects shall be the cultivation of Practical Pathology, Diagnosis and Therapeutics, by means of the accumulation and analysis of appropriate Cases and Pathological Reports, and public discussion thereon; the establishment of a Pathological Museum; and the keeping of records, to indicate the progress of discovery in Medical Science.

II. MEMBERS.—The Society shall consist of Ordinary Resident and Non-Resident, and Honorary Members—number unlimited.

III. QUALIFICATION.—The Candidates for Membership shall be regularly qualified Physicians or Surgeons.

IV. ANNUAL SUBSCRIPTIONS.—The Annual Subscription shall be *Twelve Shillings and Sixpence* to Residents, and *Seven Shillings and Sixpence* to Non-Resident Members, payable on the first day of Session, or, if a new Member, on the day of his election.

V. ELECTION.—The Candidate for Membership shall be proposed by two members at one meeting, and balloted for at the next; *one black bean in five* to exclude, and prior to ballot, the legality of his qualification shall be duly certified, and his subscription paid.

VI. HONORARY MEMBERS.—Honorary Members shall be elected only at the stated annual meeting; the names of candidates to be entered on the *Minutes* at least one month previously, and proposed by four members. When elected, they shall be free to all the privileges of membership, except share in the property, without subscription; and in the ballot for honorary members, *one black bean* shall exclude.

VII. OFFICERS.—The officers of the Society shall consist of a *President*, to be elected annually by a majority of votes, not re-eligible for three successive years after expiration of office, but entitled, as *Ex-President*, to be placed on the *Vice-President* list for one year after expiration of office, *six Vice-Presidents* (three of whom shall be chosen from the Non-Resident Members), exclusive of the *Ex-President*, two *General Secretaries* and a *Treasurer*, all to be elected annually by a majority of votes, and after expiration of office, eligible for re-election.

VIII. THE COUNCIL.—ITS FORMATION AND DUTIES.—The Council shall consist of the Office-Bearers, and six other members, who shall be also elected annually by a majority of votes.

The duties of the Council shall be to make all the necessary preparations for the ordinary weekly meetings, to examine the contributions of members, and select for reading such as may be eligible; to report, by the aid of sub-committees, upon any morbid specimen which may be forwarded by members, or examination of which may be specially requested by a

vote of the Society; to conduct the financial and ordinary business of the Society; to make bye-laws and other regulations not provided for in the stated laws of the Society; to report at the annual meeting upon all the proceedings of the session, and draw up the annual transactions.

IX. DUTIES OF THE GENERAL SECRETARIES.—The General Secretaries shall keep a record of minutes, enter the cases and notices received, or remarks furnished, in their respective books, and summon and attend all meetings of the Council and Society.

X. DUTIES OF THE TREASURER.—The Treasurer shall keep an account of all receipts and disbursements, and furnish his financial statement twice during the session, also at the close, and whenever required by a vote of the Society.

XI. CASE PAPERS.—Each member can be supplied with forms of “Case Papers,” having the annexed heading to guide him in drawing up the contributions which he may furnish. “The reporter is requested to note particularly the following points, in the reading of his case, viz.:—If from any author, the particular volume and page; if original, the place and date; in any case, his age, history, management, impressions regarding same at different periods, the termination, and P. M. examination if any.”

XI. MEMBERS’ CONTRIBUTIONS.—The contributions shall be of the following description:—

1. Cases showing unusual sequence or co-existence of diseases.
2. Do. showing any practical lesson, point, or caution, useful in practice.
3. Do. exhibiting any rare form, complication, exception to the laws of Diagnosis, Pathology, or Therapeutics; or unusual interpretation.
4. Summaries of *Medical Statistics* to prove frequency of type, average of age and mortality, and effects of remedies in any disease, or other point susceptible of proof by statistics.
5. Reports on *novel modes of practice* in any disease.
6. Morbid Specimens of Pathological or general interest, with or without case, or for Microscopic or Chemical examination.
7. Replies to *Medical Queries* proposed by members.
8. Brief *Clinical facts* of practical interest.

All contributions to be original, or original translations from authentic foreign records, not generally accessible to members.

XIII. THE SESSION.—The Session shall commence on the last Saturday in October, and terminate the first in May; and the ordinary meetings shall be held every Saturday, at three o’clock, afternoon; and the *annual meeting* the first Saturday in May.

XIV. BUSINESS OF THE ANNUAL MEETING.—The business of the annual meeting shall embrace the following subjects, viz.:—1. The Report of the Council. 2. The Report of the Auditors. 3. The announcement of the

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

New Office-bearers. 4. The Election of the New Council. 5. The Closing Address of the retiring President. 6. Installation of the President-elect.

XV. BUSINESS OF THE ORDINARY WEEKLY MEETINGS.—The ordinary sittings shall be limited to *one hour*; but, at the discretion of the President, may be extended to *one hour and a-half*: five Members to form a quorum. On the first Saturday of November, January, and March, any business may be introduced without notice having been previously given. The following shall be the order of proceeding:—

1. The chair to be taken by the President: if he be absent, by one of the Vice-Presidents present, if possible in rotation.
2. The Minutes of the previous meeting read and signed.
3. Announcements from the Council.
4. The proposal of Candidates and Election of New Members.
5. The following in such order as the Council may direct:—
 - a. The Exhibition of Morbid Specimens.
 - b. The result of Microscopical and Chemical Examination.
 - c. The Reading of Cases.
 - d. Brief notices of Clinical Facts and Summaries of Medical Statistics.
 - e. The Exhibition of New Instruments and Medicines.
 - f. Papers on New Modes of Treatment.
 - g. Debates on doubtful points in Medical Practice.

XVI. VISITORS.—Medical Students shall be admitted as visitors by official orders of Members only. Any Medical practitioner, not being a member, may be admitted as a visitor *once only* during a session, on being introduced by a member.

Surgeons and Assistant-Surgeons of the Garrison, also of the Militia and Navy on active service, may be admitted to any meeting on Members' orders.

XVII. RESERVE FUND.—*One-fourth* of the subscription money shall be set aside as a reserve fund, and deposited in bank in the names of the President and Treasurer for the time being, to the credit of the Society, and shall not be drawn thence except by a vote of the Society at the annual meeting.

XVIII. BOOKS OF THE SOCIETY.—The books of the Society shall consist of the following:—General Minute Book; Council's do.; General Proposal Book; Treasurer's Account Book; Treasurer's Receipt Book General Case Book; General Note Book for Record of Discoveries, Inventions, and interesting Medical Notes; Pathological Museum Record; Microscopical Reports; Document Book.

XIX. PROPERTY OF THE SOCIETY.—The property of the Society shall not be disposed of except by the unanimous vote of a special meeting. Due notice of

intention to take such a vote shall be given in a special circular to all members, one month previously.

XX. DEFAULTERS.—No fines whatsoever shall be imposed on members; but in case of Subscriptions more than two months due, and after two successive notices from the Treasurer, the names of the defaulters shall be struck off the Roll of Members, and they shall be ineligible for re-election during the remainder of the current session. The *last day* allowed for payment of subscriptions for *old* members shall be NEW YEAR'S DAY each Session.

XXI. EXPULSION or MEMBERS.—Members may be expelled for unprofessional conduct, by a vote of the Society, provided that such vote be carried by three-fourths of a meeting of at least twelve resident members, and that due notice of the intention to take such a vote, with grounds of the charge, be given to each member eight clear days before meeting.

XXII. PRIVILEGES.—It shall be a privilege exclusively granted to Members, to receive reports upon any morbid specimens which they may furnish for examination.

Members shall be also entitled to receive the "Transactions," being a Record of the Proceedings of each meeting during the session.

XXIII. ELECTION OF THE OFFICE-BEARERS AND COUNCIL.—Ballot papers, initialled by one of the Secretaries, together with a list of members and their attendance during the session, shall be issued to the Members on or before the third Tuesday in April. Each Member shall send forward to the Secretary his ballot paper properly filled with the names he shall select, on or before the fourth Tuesday in April. If a candidate for any office be unsuccessful, the votes recorded in his favour shall be available for the next lower office.

Council 1st meeting of Council, Wednesday October 24th 1860, 3 P.M.

Present, Professor Reid, Dr. Mulholland, Dr. William MacCormac, Dr. Aickin.

Resolved that a circular be issued calling the first meeting of this session for Saturday next to hear the President's address and transact such other business as may be brought forward.

Circular cut out and stuck into Council minute book.

The first meeting of the Society this session will take place in the Museum of the General Hospital, on Saturday, October 27, at three o'clock.

Business

Considerations arising out of minutes.

The address of the President.

The subscription—increased so as to enable the Council to forward the transactions, as published, to

every member—being 12s 6d. to town, and 7s 6d. to country members, will be received by the Treasurer, at or after the first meeting.

Members desiring to forward cases and observation to be brought under the notice of the Society, or to propose candidates for membership, will please communicate with the Secretary of the Council for the time being, Dr. Aickin, at least three clear days before the meeting.

Members of the Society have the privilege of forwarding morbid specimens, for examination by the Chemical and Microscopical Committee, and of receiving reports on their nature.

The museum of the Society is open to all members, between two and three o'clock on each day of meeting.

W. Mac Cormac, M.A., M.D.,
W. Aickin, M.D.
Honorary Secretaries.

General Hospital, October 25, 1860.

{Rough minute book:

FIRST MEETING OF PATHOLOGICAL SOCIETY
27th October 1860.

The President in the chair. Present Drs. Halliday, Dill, M'Mechan, Corry, Reid, Buckingham, Cuming, Murney, Murray, Patterson, Aickin, MacCormac, Stewart, Ferguson, M'Gee, Mulholland.

The minutes of last ordinary meeting were read and confirmed.

The President then read his opening address.

Proposed by Dr. MacCormac and seconded by Dr. Patterson that Drs. H. Burdon A.M., M.D. M.R.C.S.E., [and] D. Moore M.D. be candidates for election at next meeting.

Moved by Dr. Stewart and seconded by Dr. W. M'Gee and resolved that the thanks of the Society be given to the President for his address, and that he be requested to print it.¹

Clipping in the Council minute book from the Belfast Newsletter of November 1, 1860, page 2.

The session 1860–61 was inaugurated by Professor Gordon, the president of the society, on Saturday last, in the Museum at the General Hospital, at three o'clock. The Professor delivered an able and learned address to a large and attentive meeting, concluding with a hope that many more would unite themselves members with a society so important to the cultivation of medical science, and to the better harmonising of certain discrepancies which frequently arise in medical practice. A vote of thanks was presented to

¹ [Has not been found.]

Professor Gordon for his address, after which the meeting separated. The next meeting will take place on Saturday next, when the usual business of the session will be proceeded with.

Council 2nd Meeting of Council 31st October 1860, 3 P.M

Present, Dr. Mulholland, Dr. Mac Cormac, Dr. Aickin.

Moved by 2 and seconded by 3, That the circular be altered according to the form subjoined.¹

Subscriptions—12s. 6d. to Town, and 7s. 6d. to Country Members, will be received by the Treasurer, who requests that they will be forwarded immediately, in order that the Transactions, as published monthly, may be sent to every Member from the commencement of the Session.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

The Museum of the Society is accessible at all times to Members, or to Students accompanied by a Member.

Morbid specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretaries, with their qualifications and Subscription.

Signed by order,

W. Mac Cormac, M.A., M.D.,
W. Aickin, M.A., M.D.,
Hon. Secs.

General Hospital, Oct. 31, 1860.

Business of meeting on Saturday November 3rd.

Members for election. Dr. David Moore and Dr. Henry Burden.

Cases to be read. Dr. Moore will read notes of case of gangrene of mamma. Also case of operation for foreign body in trachea. Dr. Aickin will read notes of a case of ovarian dropsy.

{Rough minute book:
SECOND MEETING
November 3rd 1860.

Dr. Patterson in the chair. Present, Drs. Halliday, McLaughlin, Mulholland, W. MacCormac, Dill, Thompson, Johnston, Moore, Stewart, Bryce, Warwick, Ferguson, Wales, Reid, Pirrie.

The minutes of last meeting were read and confirmed.

Dr. H. Burden and Dr. D. Moore having been balloted for were duly elected members of the Society.

Dr. Moore read a case of foreign body in trachea.

Dr. Mulholland stated he had [such?] the case on the evening of the [O C A???] when he passed a [?] into the œsophagus.

¹ [Printed on a piece of paper stuck into Council minute book.]

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

Surgeon Johnston asked the Chairman if it would not be advisable to open the trachea previous to upturning the patient in order that access of air might be afforded in case the foreign body would lodge in the larynx.

Professor Ferguson considered that in the first instance there was physical evidence of the existence of the foreign body, but that subsequently there were no physical signs of its presence and that the stone was passed previous to operation.}

Council 3rd Meeting of Council, November 7th 3 P.M. 1860.

Present, Drs. Mulholland & Aickin.

The third meeting of the session will be held in the Museum of the General Hospital, on Saturday, November 10th, at three o'clock.

Cases to be read. Dr. Aickin will read notes of a case of ovarian dropsy. Dr. James Moore will read case of gangrene of breast; also exhibit foreign body removed from œsophagus.

{Rough minute book:
THIRD MEETING
November 10th 1860.

The President in the chair, Drs. Ferguson, Reade, Dill, Halliday, Johnston, Murray, Moore, Wales, Thompson, Patterson, Stewart, Aickin, Mac Cormac, Assistant Surgeon M. Brennan.

Dr. Patterson gave notice that on this day week he would bring forward for the decision of the Society what journal the transactions would be published in, and that notice of the same be inserted in the circular.

Dr. Murray was called on to read his case of gangrene of breast.

After several remarks by Drs. Dill, Patterson, Johnston, the President called on Dr. W. Aickin to read his case of ovarian dropsy.}

Council 4th Meeting of Council, November 14th 1860 at 3 P.M.

None held, there being a subject for Saturday's meeting sent to the Secretary.

The fourth meeting of the Society will be held in the Museum of the General Hospital, on Saturday, November 17th, at three o'clock.

Business. Communication respecting the illness of a late member of this Society, by Dr. Patterson and Dr. S. Reid; also, Post Mortem, by Dr. Murney.

{Rough minute book:
FOURTH MEETING.
November 17th, 1860

The President in the chair, Drs. Pirrie, T. Reade, Warwick, Ross, Bryce, S. Reid, Rea, Ferguson, Wheeler, Murney, McMechan, Patterson, McCleery, Johnston, Dunlop, Dundee, Mulholland, Dill, Stewart, Aickin, MacCormac, Thompson, Cuming, Assistant Surgeon O'Brien.

That notice be inserted on the next circular, what journal the transactions should be published in and also as to the propriety of appointing a publication committee.

Dr. Ross introduced a woman labouring under a nodulated tumour of the breast which he considered cancerous.

Dr. T. Reade did not consider that an operation would not be justifiable as he considered it was doubtful as to whether it was of a cancerous nature.

The President considered it was a case of genuine scirrhus, and that the patient would only last a couple of years, and that an operation would be of questionable advantage.}

Pulmonary Phthisis—Case of Dr. M'Minn, M.D.

Professor Reid said—The proceedings of our Society, Mr. President, become unusually interesting, when they refer, as on the present occasion, to the illness and death of a member, who a few months previously had attended our meetings; and who, when dying, gave an unequivocal proof of his zeal for the advancement of medical science, by directing a *post-mortem* examination of his body to be made, and the result communicated to the society.

The preliminary history of the case was detailed by Dr. Patterson, who said—When I first became acquainted with the late Dr. M'Minn, in the year 1835, he was then in the 35th year of his age, a remarkably fine-looking, handsome man, six feet high, about fourteen stone weight. Some years previously he had completed his studies for a Presbyterian minister, but never took out license. After this he made a trip to Canada, and travelled over the greater parts of British America. During his residence there he had a severe attack of cholera; and from this time, during the remainder of his life, he was liable to periodical attacks of bilious diarrhœa, and boils occurring on all parts of his body. He was subject all his life to great mental depression, which increased greatly during the last few years.

In 1837 he married, and went over to Edinburgh to complete his education for the medical profession. Two sisters and a brother died, in successive years, from consumption. In 1838 he graduated, and took a diploma in surgery in Edinburgh. On his return he had

frequent attacks of diarrhœa, which he regarded as salutary, and also almost constant cough and expectoration, which, he said, arose from the stomach, and that when either was checked by medicine, he was invariably worse. He also suffered from hæmorrhoids, which frequently bled—he also regarded this as beneficial. About eight years ago, when his cough was unusually troublesome, he was persuaded to give Locock's wafers a trial. On doing so, his cough and expectoration was checked; also the diarrhœa and bleeding from the hæmorrhoids—a high feverish state set in. This was the first time I professionally saw him. I ordered leeches to the anus, which was the first thing gave him relief. After some time, the cough and expectoration retarded, and he was gradually restored to his usual state. This was, I think, the last time he would take any remedy for his cough—though he consulted many medical friends their prescriptions were not taken. All this time he resided in the country, but in November, 1847, he disposed of his farm, and came to reside in Belfast. During the winter, his cough, on the whole, was better, though his spirits were greatly depressed, and he regretted giving up his farm, which had been a source of occupation. In the latter end of 1858 he lost his wife, after a protracted and severe illness. After this time he never recovered his spirits. His cough and diarrhœa became very severe, and he was urged, or rather “driven out,” as he said, to try Harrogate. He remained there six weeks, using the waters. Although he said the diarrhœa was very severe while there, he gained flesh, and the cough also improved, which continued up to Christmas, when the diarrhœa and cough again increased violently. Early in February I visited him, at the request of his sister. I found him in bed in a most desponding state. The cough was severe, with copious mucous expectoration; there were no perspirations; he never had an attack of hæmoptysis; he was suffering from one of his usual attacks of diarrhœa; the evacuations were highly offensive, as they always were when he was labouring under such attacks. He was recommended change of air, either Queenstown or some other milder climate than Belfast. For some time he positively refused, but on the 1st of March he left home, and on the following day stopped at the Hydropathic establishment at Blarney, where he remained for nearly four months, under active hydropathic treatment. On his arrival there, he was able to walk into Cork and back on the same day, which he did on several occasions during the first month. For the first three or four weeks he wrote that he was gaining flesh; that his appetite was remarkably good. From the end of the first month he wrote in the most melancholy strain—his strength, he said, giving way, and losing flesh. Still he continued the hydropathic treatment, though he complained the baths were not agreeing with him. When he returned, in the latter

end of June, it was quite evident that he had lost flesh, and was much weaker than when he left home—he was low and nervous.

Early in August he went over to Edinburgh, Dr. Simpson paid him the greatest attention, and had many medical friends to examine him, and a variety of prescriptions were given him, none of which were taken more than once or twice, except the infusion of Virginian prune, which he thought was useful, but, after using it a week or so, it checked the expectoration and diarrhœa, he then gave it up. On his return to Belfast, his depression of spirits was so great, that his friends persuaded him to go to Ballynahinch Spa, where he drank the waters, and took a great deal of outdoor exercise, both on foot and car; his spirits became more cheerful, the character of the excretions from the bowels, he wrote, were much improved, and, on the whole, he considered himself better than he had been for some time. When he had been there for some weeks a sudden change took place—the pulse, which had hitherto been quite regular, suddenly became quick and weak; urine scanty; œdema of feet and legs; diarrhœa increased; and, for the first time, he wrote asking me to send him some astringent for the bowels. I sent him chalk mixture and catechu, a few doses of which checked the diarrhœa, and it did not annoy him again during his lifetime. I advised him to give up the use of the Spa waters; on doing so, the urine returned to its usual quantity. I may here remark, it was frequently tested and was always normal; the œdema in feet and legs greatly subsided, but the prostration increased. He bore the journey home well in a carriage; it was quite evident his decease was near at hand. From the time he arrived home he gradually became weaker; he suffered from dyspnœa at intervals, which was relieved by chlorodyne. He sank on the evening of the 30th October, having been perfectly composed and tranquil up to the moment of his death.

The only pain he ever complained of was in the rectum, after having a motion; for the last six weeks, he said, he was liable to it.

Dr. Reid detailed the particulars of his physical examination of the chest, and confirmed Dr. Pater-son's account in his review of the history and general symptoms. He said the disease was senile phthisis, brought to a premature termination by failure of the heart's action from atrophy of its muscular tissue.

The following is an account of the *post-mortem* and microscopic examinations, by Dr. Murney, and also the results of an analysis of a portion of the calcareous deposit in the right lung, by Dr. Cuming:—

“*Post-mortem* examination on the body of Dr. M'Minn, at a quarter-past ten o'clock, A.M., on Thursday, the 1st November, thirty-eight hours after death, in the presence of Drs. Patterson, H. Ferguson, Moore, Reid, Cuming, and Mr. Aickin:—

“Some slight rigidity of the limbs, as the rigor mortis had not passed off completely. On cutting through the soft parts to open the chest, the greater pectoral muscles were found atrophied; in fact, but a mere trace of the muscular structure remained. In the bag of the pericardium about two or two and a half ounces of clear serum was found.

“*The Heart.*—On the surface were three ‘lymph spots.’ The organ was rather larger than natural; its structure soft and flabby. I had not the means of weighing it, but consider it was about ten ounces; had its tissue been dense and normal, I would have calculated the weight at twelve or thirteen ounces. The thickness of the walls, and capacity of the cavities were natural; the mitral valves healthy; The aortic semilunars presented on the outer or arterial aspect of each at its base a hard calcareous-like nodule; there was no deposit or growth on the ventricular surface. A piece of the wall of the left ventricle was removed for examination, and submitted by Dr. Cuming to the microscope. He states he observed absence of the striæ in the muscular structure, but noticed no very large globules, but a large number of granules and oil matters. Subsequently the specimen was given to me. I also was unable to find the transverse striations; but on the addition of acetic acid, I think I witnessed a greater number of oil globules than were seen by my friend; at the same time, the number was very inconsiderable. I conclude, therefore—and in this statement I am joined by Dr. Cuming—although not a well marked example of fatty heart, the softened texture and microscopic appearances indicate the early stage of that degeneration. A few small patches of atheromatous deposit were found at the commencement of the aorta.

“*The Pleura and Lungs.*—Several old adhesions of the right pleura were found, more especially at the upper part; similar connections existed on the left side, but much stronger; in fact, in breaking them down to remove the lung, the apex was torn in two places. The lobes of the right lung presented to the touch the nodulated sensation customary to phthisis; on being cut into, tubercle was scattered in all parts, even to the base—of different degrees of consistence, the soft or semifluid, cheesy-like, and the hard chalky concretions. The latter were only found in the apex; no cavities were found here. In the left lung similar diseased conditions were found, but much more extensive; the masses of tubercle were, in many places, larger; and some vomicae were opened in the apex, from the size of a pea to that of a small walnut. I may add, the tissue of the upper lobes, on both sides, readily broke down under manipulation.

“The liver was of normal size and consistence. It presented on the upper surface of the right lobe three broad sulci, as if indentations produced by the ribs. They could not, however, have been produced by this

cause, as they passed vertically. Section presented the appearance of some fat; the lobules were in the condition of the first stage of venous congestion; under the microscope, a considerable amount of fat was observable; otherwise the tissue was natural. A small piece of the pyloric end of the stomach and upper part of the duodenum was laid open, and was found perfectly healthy.

“The physicians who had visited Dr. M’Minn declared it was unnecessary to prosecute the examination farther. I did not, therefore, remove the other abdominal viscera, nor was the head opened.”

Dr. Cuming stated that the cretaceous mass which he had examined consisted mainly of phosphate of lime, with some phosphate of magnesia and carbonate of lime. There was about eleven per cent. of organic matter in it. He said that he had been surprised to observe a statement in the work of Messrs. Sieveking and Jones, on Pathological Anatomy, to which his attention had been drawn by Professor Reid, that these concretions consisted of sulphate of soda and chloride of sodium. Such was certainly not the fact; and he was at a loss to conceive how salts of such marked solubility could possibly exist as concretions in the lungs.

Dr. Reid then resumed his remarks:—

The *post-mortem* examination having discovered cavities at the apex of the left lung, and the microscope atrophy of the muscular substance of the heart, confirms the opinion I had given, as to the nature and localities of his disease. The examination revealed another fact, viz., that disease was rapidly disorganizing the entire substance of both lungs. In addition to calcareous deposit (of course, of old standing) at the apex of the right, tubercular deposit had recently invaded the middle and lower portions of both lungs; and though the liver was found of natural size, yet a considerable amount of fat was deposited in it; a change which, when unaccompanied by enlargement, we have no means of detecting during life.

The different conditions in which the deposit was found at the apices and bases of the lungs, warrant, I think, the conclusion, that two deposits of tubercle had taken place, and at considerable intervals of time; the first at the apex, and the second lower down; that at the right apex was changed into calcareous matter, the qualitative and quantitative composition of which has been so fully ascertained by Dr. Cuming; whilst that on the left, if also changed into earthy matter, had been expectorated, and originated the cavities that have been mentioned. It is, therefore, not improbable that our friend was saved from dying of phthisis in early life (like some other members of his family) by the tubercular matter becoming changed into calcareous.

The opinion that there were two deposits is also supported by the firm adhesions that existed at the

tops of both lungs; that on the left being so firm, that the substance of the lung was torn in separating it; indicating clearly that a cause of irritation had long ago existed there, and had produced a localised plastic pleuritis.

The second deposit had taken place in the middle and lower portions of both lungs, and was evidently of a more recent date, as no portion of it had yet taken on the process of softening.

The case is instructive to us all, by showing how necessary it is to have healthy lungs as a standard for comparison when practising percussion. In this case, the existence of very great dulness below the left clavicle, masked whatever was produced by the calcareous deposit below the right one; and as tubercular deposit existed at the back base of both lungs, the percussion sound was the same in each, and the existence of deposit there was, in consequence, not detected.

So convinced was our friend that his disease was seated in the digestive organs, that he had been studying Dr. Johnson's work on Indigestion, and had found a case recorded, in which the same severe pain had existed in the rectum, whilst the only cause found after death for it was an aneurism in some portion of the arch of the aorta. I could detect no pulsating tumor along the abdominal aorta; and it entirely escaped my memory to have the lower portion of the intestines and the cavity of the abdomen examined carefully after death, in the hope of discovering its cause. I am under the impression that this peculiar pain in the rectum had been noticed by the late Dr. Marshall Hall, in some of his writings; but I have not been able to find the passage in either of his volumes on "Observations on Medicine," though I have a distinct recollection of his mentioning it as an ailment that could be relieved by some kind of manipulation about the sphincter ani muscles.

I cannot close this communication without expressing a feeling of deep respect for the mental constitution of our late friend; for whilst we can all be eloquent on the propriety and advantages of *post-mortem* examination, it requires a high caste of intellectual endowment to direct examinations to be made of our own bodies, with the sole object of advancing science and benefiting mankind.

Council 5th Meeting of Council, November 21st 1860, 3 P.M.

Present, Drs. Dill, W. MacCormac, Aickin.

[Preparation of Circular.]

Questions for discussion.

1. In what periodical the transactions of the Society for the current session were to be published.
2. The propriety of appointing a Publications Committee.

Cases to be read.

1. Dr. Murney will read notes of case of disease of foot.
2. Dr. Browne and Dr. Murney will introduce patient and give history of case of recovery from fractures of arm and forearm.

Patients to be exhibited.

1. Man with congenital absence of anterior wall of bladder.
2. Mr. Hanna will bring forward a child with a large ulcer on back.

Resolved that the first 12 pages of the transactions be issued with this notice.

Letters were received from Dr. Patterson Tandragee, and Dr. E. J. Bruncker, Dundalk, withdrawing their names as members.

To be proposed for membership. H. Purdon, Jun., M.R.C.S., Edin.

FIFTH MEETING.

November 24th, 1860.

Dr. Patterson, V.P., in the chair.

{Rough minute book: Present, Drs. Stewart, Cuming, T. Reade, Ferguson, J. Moore, Thompson, S. Reid, Rea, Murray, Johnston, Warwick, Mulholland, Dill, W. Aickin, W. MacCormac, Pirrie, Wales, Drennan, Halliday, Bryce, Mac Laughlin.

A majority having been declared in favour of publishing the transactions in the Dublin Hospital Gazette, it was resolved that for the current session the transactions be published in that journal.

A discussion then arose as to the propriety of establishing a publication committee. It was voted that the communications should be published as hitherto.}

Dr. Halliday presented a patient with a fluctuating tumor around the first finger. He stated there was no pain, and considered it non-malignant.

{Rough minute book: Dr. S. Reid stated that before he would pronounce his opinion, he would examine the nature of the ...

Dr. Murney expressed a similar opinion.}

Dr. Murney exhibited a case of *epispadias* in which the anterior wall of the bladder was absent. The testicles were contained in folds similar to the labia majora, ascending and descending according to the variations of the temperature. The urethra was imperforate. The penis was capable of erection.

Dr. Dill exhibited a child with spina bifida. At first the lesion appeared like a simple ulcer, and the character of the disease was not manifest.

Council 6th Meeting of Council, November 28th 1860, 3 P.M.

Present, Drs. Murney, Patterson, Mac Cormac, Mr. Browne & Dr. Aickin.

[Preparation of Circular.]

To be balloted for membership. H. Purdon, Jun., M.R.C.S. Edin.

Cases to be read.

- (1.) Mr. Browne and Dr. Murney will introduce patient and give history of case of recovery from fractures of arm and forearm.
- (2.) Dr. Murney will read notes of case of disease of foot.
- (3.) Dr. Murney will give report of operation for strangulated hernia and post-mortem.

For exhibition.

- (1.) Dr. Moore will exhibit cancerous disease of superior maxilla removed post-mortem.
- (2.) Dr. Mac Cormac will present photograph of the congenital absence of anterior wall of bladder exhibited at last meeting.

SIXTH MEETING.

December 1st, 1860

Dr. Patterson, V.P., in the chair.

{Rough minute book: Present, Dr. Wales, Moore, Thompson, D. Moore, Rea, Murray, Dill, W. Aickin, W. MacCormac, Browne, Johnston, Warwick, Murney.}

Dr. Browne introduced a patient who had recovered from a fracture of the ulna and radius together with a fracture of the humerus. The arm was at first completely distorted, and doubts were entertained as to the possibility of saving the limb. It was, however, put up in a gutta percha splint, and now, at the end of six weeks, complete recovery had ensued.

Amputation of Foot.

Doctor Murney showed a portion of foot, which he had amputated by Chopart's operation.

The patient, a young gentleman, has, for the last twelve months, labored under brown fibroglutinous degeneration of the synovial membranes of the small articulations of the tarsus and metatarsus. The operation had been deferred, at the request of the sufferer, until the loss of appetite and sleep, with other symptoms of irritation, indicated immediate removal. After the lapse of three weeks, the stump is almost completely united. He has not had a single bad symptom. From the day of operation his appetite was restored. He now rests without the use of anodynes, and is beginning to get fat.

Case of Femoral Hernia.

Dr. Murney also shewed a specimen which he had removed from the body of a patient on whom he had

operated for strangulated hernia, and who died thirty-six hours subsequently. The following report was given:—

A woman, aged 50, labored under reducible hernia for twelve months. On the 20th November, when crossing the street, the tumor became irreducible. She was admitted into hospital on the 21st; and thirty hours after the increase of the protrusion, having constant vomiting of the contents of the duodenum, and other symptoms of strangulation, chloroform was administered, and the taxis being tried without success, the usual operation was performed. Cutting down to and opening the sac was effected with great facility. It contained omentum only, somewhat, but not greatly congested. A stricture at the usual situation was relieved, and the protruded parts returned. In doing so my nail twice caught upon a firm band of lymph, situated anterior and external to the ring. This was cut, the parts dressed, and the patient taken to bed. At the time, the prognosis was more favorable than in a similar case of femoral rupture, on which I operated a week before; yet the more unpromising case recovered, and she, with brighter prospects for a few hours only, seemed to be relieved by the operation, and sank with symptoms of strangulation on the morning of the 23rd, sixty-six hours from the commencement, and thirty-six from the time of operation. For eighteen hours after section of the stricture, pain at the umbilicus and vomiting became much less frequent, but then returned, and continued almost constantly until death. The friends would not permit a proper examination *post mortem*, so I merely examined the parts adjacent to the wound, ten hours after the termination of life. The opening through which the hernia had passed was quite free. A piece of small intestine projected into it, but was not subject to the least compression. On enlarging the wound, fresh lymph was poured out freely on the visceral and parietal layers of peritoneum of the inguinal region. For about one foot in length, the vessels of the small intestine were congested, apparently the extension of irritation from the region of the femoral ring. Nearly every portion of the small and large intestines was examined through the wound, but, with the exception of the parts referred to, nothing was noticed. Close in front of the femoral vein, near the band of fibrine which was divided during the operation, lay a little pouch of serous membrane, about 1¼ inch in depth, sufficiently wide at the bottom to hold a shilling, with an orifice only large enough to admit a No. 4 catheter, puckered and appearing to have been as dilated as its cavity, but contraction of the lymph had caused it to assume its present appearance; it bearing a good resemblance to a purse or bag provided with a "string-case" drawn tightly.

Now, although the abdominal cavity was not freely laid open, so as to permit an examination of the dif-

ferent viscera, I have no doubt all the parts in any degree implicated in causing the strangulation were exposed. The feeling of the constriction before its division, and the appearance of the protrusion, shewed distinctly it was not what would be designated a tight stricture; no doubt quite sufficient to cause the symptoms, which, however, yielded upon its relief. I therefore think we cannot attribute the condition of the patient for the last eighteen hours *directly* to injury done by the stricture to bowel or omentum but ascribe it to the formation of this bag of peritoneum, which, I believe, did not exist until after the hernia became irreducible, was, in fact, created by the lymph poured out during the inflammation, and as this underwent organization, the orifice become more and more contracted. Why a condition of parts, such as I have described, not involving any vital organ, and certainly not interfering *directly* with the peristaltic movements of the intestine, should produce fatal results, I am unable to say; but we have all had ample experience that such terminations are not unfrequent.

Dr. Browne remembered having operated on a case where the peritoneum formed a band tying down the bowel, outside the position of the internal ring.

Society agenda from Council minute book.

The seventh meeting of the Session will be held in the Museum of the General Hospital, on Saturday, December 8th, at three o'clock.

Cases to be read.

Dr. Browne will read notes of case of disease of eye.

To be exhibited.

1. Dr. Moore will exhibit cancerous disease of superior maxilla, removed post mortem.
2. Surgeon Johnston will exhibit child with ossification of muscles.
3. Surgeon Warwick will exhibit case of cyanosis.

SEVENTH MEETING.

December 8th, 1860

The President in the chair.

{Rough minute book: Present, Drs. Ferguson, Patterson, Dill, Halliday, Rea, S. Reid, Dr. Moore, Mr. Purdon, Drs. D. Moore, Drennan, Dunlop, W. MacCormac, Browne, Stewart, Warwick, [?], Johnston, Bryce.}

Cases of Excision of Eye.

Dr. Browne read the following:—During last session, I brought under the notice of the Society three cases in which I had found it necessary to remove the globe of the eye. Two of these were removed by excision, in consequence of the irritative inflammation induced

and kept up in the uninjured eye, by a foreign body which had been in the opposite eye for some time. The other was extirpated for melanosis of the organ. In this case the disease has returned.

I have now to bring before the Society the brief notes of two additional cases of excision of diseased eyes.

The first is that of a young lady from the country, aged eight years, who was first brought to me in September, 1859, in consequence of her parents having observed something unnatural in the appearance of the left eye, and loss of sight in it. Upon dilating the pupil and examining the organ, the bottom of the eye presented a dull white appearance, and the ophthalmoscope revealed a prominence on the right side of the centre of the retina, with enlarged vessels passing on it. The retina seemed totally insensible to light, though the pupil, before the use of the atropia, contracted under its stimulus, evidently through sympathy with the healthy eye. At that time I advised the parents to bring the little girl to me at the end of three months, and, as she was not suffering any pain, and was in excellent health, I prescribed nothing for her. She did not return till July, 1860, when I found the aspect of the eye considerably altered; the growth seemed to have advanced toward the front; the vessels radiating on the growth were visible to the unaided sight; the conjunctiva was injected, and there was constant lacrymation; besides which objective symptoms, she had constant severe pain in the eye, brow, and head, and her general health had become affected.

Under these circumstances, though I could not pronounce the disease malignant, I thought it right to advise extirpation of the diseased organ. The operation was accordingly performed on the 8th of July. She made a rapid recovery, and remained quite well till the end of September, when her health began to fail, and constant severe pain in the head to be felt. Although the orbit has not yet exhibited any disease, I fear very much that the optic nerve within the skull is diseased, and that the case will prove to be one of fungus hæmatodes.

The diseased eye was examined after extirpation by Professor Gordon, who looked upon the case as non-malignant, as he could not discover any cancer cells, only exuded lymph and granular deposit at the bottom of the eye.

The next case is that of J. B. Dunlop, aged thirty-five, who applied to me early in August last. He stated that in the month of May, or early in June, he had observed his right eye to become bloodshot and painful every evening, with some dimness of sight; for this he was treated by a careful and experienced practitioner in the country. The disease, however, increased, the cornea gave way, the globe became greatly enlarged and exceedingly painful.

When he applied to me, the eye presented a very suspicious appearance, being very much enlarged, projecting from the orbit, and of a dusky red color, the blood-vessels being large and tortuous. There was constant pain in the part, and a considerable amount of sympathetic irritation in the left eye. The only remedy was excision, and that operation I performed early in September. He made an excellent recovery, and has remained quite well ever since.

The diseased eye was exhibited, and shewed a lobulated appearance within the sclerotic, the entire structure being filled up with organized lymph, presenting much the appearance of the vitreous humor, as figured by M. Bannon in his paper on the structure of that body. The case was regarded as non-malignant.

{Rough minute book: Resolved proposed by Dr. Ferguson and seconded by Dr. Moore That a notice inviting medical students to attend the Society meetings be posted in the hall of the Hospital and also of the College.}

Cyanosis.

Dr. Warwick exhibited a case of cyanosis in a child eighteen months of age. He said—According to her mother's report, this child enjoyed good health for about two months after her birth. I saw her for the first time about six months ago, when I found her laboring under a succession of violent paroxysms and remissions, accompanied with venous congestion, great difficulty of breathing, coldness of body increasing towards the extremities, as well as lividity of face, hands, and feet.

There is distinct pulsation of the jugular veins at all times, which are very much dilated during the attack, especially the left, which is much larger, caused by regurgitation of blood from the venous side of heart. I think I have been able to detect a distinct murmur, not only over the apex, but also over the base of the heart. She has become greatly emaciated and very peevish, sleeps badly, and takes very little food. She has a great desire for cold liquids, such as water and milk, which she consumes in large quantities, while the father of the child has told me that hot tea will produce a fit.

Dr. Browne asked if the symptoms might not be ascribed to mere anæmia.

Professor Ferguson found, on auscultation, a very intense murmur, which he found difficult to localise. He did not consider anæmia as a sufficient cause for the child's present condition.

Dr. Drennan stated his opinion; that to be a case of open foramen ovale it was by no means necessary that the child should manifest lividity immediately after birth.

The President considered the case one of imperfect septum.

Dr. Johnson read notes of, and exhibited a case in which there were extensive osseous deposits in a number of the muscles.

Society agenda from Council minute book.

The eighth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, December 15th, at three o'clock.

Cases to be read.

Dr. Pirrie will read case of intussusception, and exhibit the recent parts.

To be exhibited.

Dr. Moore will exhibit cancerous disease of superior maxilla, removed post mortem.

EIGHTH MEETING.

December 15th, 1860

Dr. Patterson, V.P., in the chair.

Dr. W. MacCormac introduced a patient with aneurism, probably of the ascending aorta. It formed a swelling of the magnitude of half an orange, in front, and to the left side of the sternum. The patient enjoyed capital health, and positively asserted that, until two months previously, there had been no appearance of the swelling.

Surgeon Johnston introduced a child with a vascular tumor situate in the cheek, and alveolus of the left side. When the child cried oozing from the gums in the vicinity took place.

Case of intussusception.

Dr. Pirrie reported the details of a case of intussusception in a healthy infant four months old.

Dr. Pirrie had arrived at a correct diagnosis of the case during life chiefly from the suddenness and severity of the abdominal symptoms, and the long-continued efforts at straining without the evacuation of anything but a little bloody serum.

The *post-mortem* examination showed that the cæcum had entered and passed along the ascending colon, and through the sigmoid flexure, till it had almost reached the top of the rectum, where two ulcers had formed on the sheath of the volvulus, opening into the peritoneal cavity.

Models in wax of this interesting specimen, shewing the relative position of the parts of the intestine involved, are preserved in the Museum of the Society.

Society agenda from Council minute book.

The ninth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, December 22nd, at three o'clock.

To be exhibited.

Dr. Moore will exhibit cancerous disease of superior maxilla, removed post mortem.

Also, foreign body removed from œsophagus.

NINTH MEETING.

December 22nd, 1860

Surgeon Browne in the chair.

{Rough minute book: Present, Drs. Moore, D. Moore, Mulholland, Johnston, Murney, Murray, W. MacCormac & W. Aickin.}

On a report from Dr. Murney on the case of tumor of cheek, exhibited by Surgeon Johnston at last meeting, a discussion arose in which Dr. Murney, the chairman, Dr. Johnston, and Dr. Moore took part.

{Rough minute book: Resolved that the Society do adjourn till 1st Saturday in January.}

Society agenda from Council minute book.

The tenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, January 5th, at three o'clock.

To be exhibited.

Dr. Moore will exhibit cancerous disease of superior maxilla, removed post mortem.

Also, foreign body removed from œsophagus.

Dr. Drennan will introduce a child suffering from deep ulceration of the parts around the nose after small pox.

TENTH MEETING.

January 5th, 1861

Dr. Patterson, V.P., in the chair.

{Rough minute book: Present, Drs. Moore, Dill, Ferguson, Rea, Wales, Thompson, W. Aickin, Drennan, Mulholland, W. MacCormac, Johnston.}

Dr. Drennan introduced a child with extensive gangrene in the region of the mouth and nose, and with the same lesion manifesting itself in different parts of the body.

{Rough minute book: Dr. Thomas Reade has found application of citric acid to be beneficial in such cases.}

Dr. Moore exhibited an example of cancer of superior maxilla. The disease commenced in the base of the tongue, attended with difficult deglutition. It rapidly extended, until it involved the larger portion of the superior maxilla, and ran its fatal course in about three months.

A large pebble was exhibited by Dr. Moore, which had been swallowed by a patient in the Lunatic Asylum. It was lodged in the œsophagus, and was there felt by Dr. Purdon, who was, however, unable to seize it. The patient drank a large quantity of water, both before and after he had swallowed the stone, and by this means emesis was induced, and thus the stone was forcibly ejected.

{Rough minute book:

ELEVENTH MEETING

January 12th, 1861.

Dr. Bryce V.P. in the chair, Drs. Warwick, Murney, S. Reid, Murray, O'Brien, Johnston, W. Aickin, Moore, Dill, D. Moore, W. MacCormac.

Moved and seconded and unanimously resolved at the meeting of the Clinical and Pathological Society of the 12 January 1861

That the members of the Society regret the repeated absence, and the apparent want of interest manifested by the President in the business and welfare of the Society, the more so as they were not led to anticipate such an event from aspirations contained in his president's opening address.

Moved by Dr. Dill and seconded by Dr. Reid that a copy of the forgoing resolution be forwarded to the President.

Moved by Dr. Murney and seconded by Dr. Moore

That the Secretaries be instructed to call a special general meeting of the Council on Wednesday 16th inst, and that the circular bear the following

I am directed to call your attention to rules 7, 8, 9 in which you will find it is a portion of your duty to aid the other officers in preparing for the business of the Society.}

Council 11th (Special) Meeting of Council, January 16th 1861, 3 P.M.

Present, Drs. S. Reid, Dill, Mulholland, Mac Cormac, Aickin. Dr. S. Reid in the chair.

The Secretary reports that a copy of the resolution of the Society was forwarded on last Saturday to Dr. Gordon.

Letters were received in reply, and directed to be laid before a special general meeting to be summoned on Saturday 19th January 3 P.M.

The notice to contain

Business. To consider letters received from the President and adopt such measures as may be necessary in consequence of their content.

To be exhibited. (1) Professor Reid will exhibit morbid parts and give history of case. (2) Dr. Corry will introduce a patient with an enormous inguinal hernia.

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

{Rough minute book:
TWELFTH (SPECIAL GENERAL) MEETING
19 January 1861

Dr. Patterson, Dr. Magee, T. Reade, J. Moore, J. Cuming, S. Reid, Mr. Purdon, Browne, Drs. Murray, Warwick, Drennan, Corry, W. Aickin, W. MacCormac, Pirrie, D. Moore.

Moved by Dr. S. Reid and seconded by Dr. Dill that the minutes of last meeting be confirmed.

Moved as an amendment by Dr. McGee and seconded by Dr. T. Reade that the minutes of last meeting be not confirmed.

A show of hands having been taken the majority declared for the amendment.

Moved by Mr. Browne and seconded Dr. Stewart that the President be furnished with a copy of the foregoing resolution and that his letters be returned as unopened.}

Dr. Corry introduced a man subject for many years to an immense scrotal hernia. The tumor varied somewhat in bulk, but was about the size of the man's head. It was irreducible, and Dr. Corry had constructed a large bag by which adequate support was afforded.

Dr. Moore exhibited four fingers removed from a boy's hand, in consequence of injury received from a circular saw.

He also exhibited a hand which he had amputated just above the wrist, in a man of sixty years of age. The injury had been sustained by the hand passing diagonally between two cog-wheels belonging to a threshing-machine.

Complete laceration had taken place in consequence, necessitating removal of the entire member. The operation was performed four hours after the accident, without chloroform, at the wish of the patient. Compression was maintained so perfectly throughout, that no blood was lost during the operation, and, on the third day after, union by the first intention had taken place.

Council 12th Meeting of Council, January 23rd, 3 P.M. Present, Dr. Patterson in chair, Drs. Corry, Browne, Drennan, Mac Cormac, Aickin.

Notice to contain. For exhibition

- (1.) Professor Reid will exhibit morbid parts and give history of case.
- (2.) Dr. Moore will exhibit cancer of mamma removed by operation.
- (3.) Also a patient affected with a peculiar form of skin disease.

THIRTEENTH MEETING.

January 26th, 1861

The President in the chair.

{Rough minute book: Murney, Wales, Professor Ferguson, Drs. Magee, Patterson, Halliday, M'Cleery, S. Reid, Purdon, Rea, Cuming, Mulholland, W. MacCormac, Stewart, Dill, Moore, Aickin, Browne, D. Moore, Murray, Bryce, Johnston.}

Disease of the Pancreas.

Professor Reid stated—I exhibit to-day some morbid parts removed from the body of a patient who died early last summer.

His age was forty-four; and he stated at my first interview with him that he had been subject to frequent attacks of vomiting during the previous three years; that the matters ejected were very acid, and often contained "sooty-looking" matter, or what we would have described as "coffee grounds."

The case possessed two points of diagnostic interest. First, with reference to a tumor that was felt in the region of the pyloric orifice of the stomach; and secondly, with respect to the frequency of vomiting.

At first a very hard, knotty tumor was felt in the region of the pylorus, and could be traced extending in a semicircle to near the margin of the right ilium. After a few days had elapsed, this tumor became much less distinct, and might have escaped detection on a cursory examination. In this way it would be on some occasions quite perceptible, whilst again it would be much less so. It was always, however, felt to be of the semi-circular form I have described. There was no enlargement of the veins of the abdomen, or of the limbs, nor did the latter ever become œdematous.

He stated that at first vomiting generally occurred about three quarters of an hour after taking food. In a few days, however, the period and frequency of its occurrence changed; and during a period of five weeks it took place regularly on every second day, and at varying intervals after taking food. These changes were so well marked as to attract his own attention. During the succeeding two weeks, the vomiting did not occur oftener than every fifth day. This was followed by a remission of remarkable duration, for no vomiting took place for a period of three weeks, which excited in him much hope of recovery, as he had not enjoyed so long a respite at any time during the previous three years. After this it appeared at very regular intervals, and which became shorter as his life drew to a close.

The colour of the matters vomited varied much, being sometimes yellow, then changing to green, and during the last few days chiefly of a "coffee-ground character."

The evacuations from the bowels presented nothing peculiar in their appearance, and although minutely examined, no fatty matter was ever observed in them. The emaciation of the body increased steadily, notwithstanding the long intervals between his attacks of vomiting. He suffered much from mental depression, and seldom spoke to any one.

On post mortem examination no fluid was found in the peritoneal cavity, although the vena cava was encircled by the tumour. The stomach was found much dilated; its mucous membrane free from any ulceration, though stained from ecchymosis in several parts. The posterior portion of the pyloric orifice was found intimately adhering to a tumor, but the anterior was not, and the forefinger could be passed freely through it, the elasticity of this portion being quite unimpaired.

A hard knotty tumor was found crossing the spine, involving the pancreas, surrounding the vena cava, adhering, as already stated, to the back of the pylorus, implicating the omentum, and with it forming the semi-circular hard tumour that was so often felt to the right of the mesian line during life.

Dr. Moore exhibited a *cancerous tumor of mamma* which he had excised. He also introduced a patient labouring under general *ichthyosis*.

Dr. Pirrie exhibited a *diseased uterus*. The cervix and body were very much elongated, and the fundus was occupied by a large fibrous growth. For upwards of three months this patient had been in hospital. She had been admitted for rheumatic pains of a trifling description. About a fortnight subsequently she complained of intense pain in the right knee, and soon afterwards the thigh and lower limb of that side swelled very considerably. This condition gradually became worse and worse, until the entire member was double the size of the other limb. No local tenderness was discovered along the course of the veins, but the general aspect indicated phlebitis. The woman was about fifty years of age, and had had children, but no uterine symptoms were complained of. On one or two occasions she suffered from temporary retention of urine.

On examination after death, the uterus was found, as described above, lying over the right common iliac vein. The vessels on that side were, with surrounding cellular tissue, matted together as the result of long standing inflammation, and a tuberculous matter was found in considerable quantity in the neighbourhood. The right femoral vein was found to be plugged up with a mass of lymph. The iliac veins, and all the veins of the left side, were free. The veins on the affected side were not traced further, owing to the great obesity of the subject, nearly two inches of fat being found in the sub-cutaneous cellular tissue.

Professor Ferguson asked if the presence of such a tumor of the uterus could be accounted an adequate cause for such an extensive lesion of the veins.

Dr. Murney, who performed the *post-mortem*, believed that, as the site of venous obstruction was the femoral, the uterine tumor which lay over the iliac vein could not be considered the primary cause.

Dr. Pirrie thought it probable that the uterine tumor was the starting point of the disease.

{Rough minute book: Dr. Bryce asked if any other veins were diseased.

Dr. Murney stated that from the great obesity it was difficult or impossible to detect in life any affection of veins, and no veins were seen after death but those specially sought for.}

The President thought it probable that the venous system of the entire limb was diseased, although the lesion only extended upwards as far as the profunda femoris.

Society agenda from Council minute book.

The thirteenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, February 2nd, at three o'clock.

Business.

Dr. Drennan will exhibit heart and lungs of asthmatic patient.

FOURTEENTH MEETING.

February 2nd, 1861

The President in the chair.

{Rough minute book: Drs. Ferguson, M'Gee, Patterson, S. Reid, Warwick, Rea, Drennan, Aickin, MacCormac, Burden, D. Moore, Pirrie, Cumming, Bryce, Mulholland, Dill, Browne.}

Dr. Drennan exhibited the heart and lungs of a woman aged between thirty-five and forty, who had for twenty years suffered from bronchitis and dyspnoea; her cough had latterly subsided, but her asthmatic symptoms had become much aggravated, and were accompanied, on her admission to hospital, eleven days before death, by anasarca swelling of feet and legs. The chest was of rounded form and limited motion, with a clear sound and feeble respiratory murmur throughout; a loud bruit was heard with the first sound at the apex of the heart, and the jugular veins were tortuous, distended, and pulsating.

The *post-mortem* examination revealed strong and extensive pleuritic adhesions on both sides, and distended lungs, presenting, round their edges especially, numerous projecting sacculi, from which the air could be with difficulty expressed. The right heart was much dilated, and slightly hypertrophied; both

mitral and tricuspid orifices were abnormally patulous. Dr. Drennan considered the case as a typical one, both as to symptoms and morbid anatomy.

Dr. S. Reid referred to the difference of opinion entertained by Drs. Stokes and Walsh, with reference to friction sounds as diagnosing the particular form of disease.

The President considered that the intensity of friction sounds depended very much on the state of the rubbing surfaces, whether they were moist or dry.

Dr. Ferguson said that the dry crepitus described by Laennec was not to be confounded with the rough sounds produced by effused lymph.

Anasarca.

Dr. Dill exhibited the brain and kidneys of a patient who died in hospital last night, at eleven o'clock, in convulsions. He was sent for about two o'clock to see a patient just admitted, suffering from acute anasarca, with convulsions. On his arrival he found the breathing stertorous, with great labour and distress, and congestion of face. Pulse was quick and flagging. The pupils were dilated and fixed, especially the left. The convulsions were often repeated until the time of death, which took place during one. The patient was a man of twenty-nine years of age. He was large, stout, and fat, and of generally healthy appearance. There was not much appearance of anasarca during life, but some was apparent after death.

Dr. Johnston said that the patient came, on Thursday last, to the dispensary, complaining of a cold; had puffy eyes and cheeks; never before had fits; told him to encourage the action of the skin; and gave him a purgative powder; saw him at his home on Friday morning; he was then heavy, restless, and somewhat stupid, not inclining to rise. He had three convulsions before being sent to hospital. He was conscious after the first two but not after the third. The habits of the patient had been intemperate.

Dr. Murney had made a *post-mortem* examination. The brain surface was covered with blood. The veins and structure were very much congested. The substance and ventricles contained no effused blood. The brain seemed very healthy. The kidneys were both much larger than normal, especially the right, which was very much congested. They each weighed about six ounces, being two ounces more than normal. The structure of the left kidney was completely altered, being paler than in health. No urine could be procured during life, but after death two ounces was procured from the bladder, which appeared more like thin porridge.

It was found to be completely albuminous.

Dr. Pirrie said that of course the congestion of the brain was secondary, depending on the previous state of the kidneys, very similar to cases of puerperal convulsions.

Dr. Ferguson observed that this form of disease was like another form of apoplexy, that the two diseases are too often amalgamated, and that a very large proportion of deaths, apoplectic so called, are examples of this, the true form of Bright's disease.

Dr. Drennan detailed the case of a sailor who died with similar symptoms. The form, however, was rather coma; the case appeared to result from disease of kidneys, but, after death, there was no appearance of unhealthy structure in either brain or kidneys; there was, besides, no albumen discoverable in the urine.

Dr. Pirrie referred to the case of a servant of this hospital who has had several attacks of convulsions with coma, one of which attacks lasted five days. He is the subject of albuminuria.

Society agenda from Council minute book.

The fourteenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, February 9th, at three o'clock.

Business.

The President and Dr. Browne will each exhibit examples of extensive tearing of skin off the hand by mill accident.

FIFTEENTH MEETING.

February 9th, 1861

The President in the chair.

{Rough minute book: Ferguson, Patterson, Thompson, D. Moore, Cuming, Mulholland, Purdon, Browne, Dill, Bryce, Aickin.}

Amputation of Hand.

Dr. Browne exhibited a hand removed by operation after a mill accident. The skin had been torn down off it like a glove, and the hand itself greatly mutilated. He remarked that in all such accidents it seems necessary to remove the injured parts at a point higher than the apparent injury, as the stretching of the soft parts render them liable to extensive sloughing.

The President exhibited one very similar, but not so much mutilated. Had two former cases of more extensive tearing, from the elbow down, followed by tedious inflammatory action, rendering the limbs almost useless. The cases referred to were not healed after eight months, so that experience would show the necessity of operation immediately, or within a few days after accident.

An interesting discussion ensued between Dr. Ferguson and Drs. Browne and Gordon with reference, (1) to allowing the integument to be replaced over the

denuded bone and soft parts, in such cases as might be given a chance of healing without operation; (2) the comparative merits of reapplying the raised integument, or application, such, as cotton wool, lint, and unctuous dressings; (3) the comparative vitality of integument torn up or down off the arm, and compared with vitality in the scalp; (4) the nature of the anatomical formation of that covering which replaces lost integument.

SIXTEENTH MEETING.
February 16th, 1861
The President in the chair.

{Rough minute book: Drs. Halliday, Patterson, Graves, Dill, Reid, Rea, D. Moore, Browne, MacCormac, Ferguson, Johnston, T. Thompson, Dr. Moore, Dr. Pirrie, Drs. Scott & O'Brien.}

RHEUMATISM.

Dr. Graves brought under the notice of the Society the therapeutic action of the tincture of *actea racemosa* in cases of acute rheumatism. He had tried it in several cases successfully, and had failed in only one case, when he had recourse to the opiate treatment. The disease generally yielded in about four days, and in no instance was the treatment prolonged beyond seven days. In none of the cases was there any cardiac affection. The dose was thirty drops thrice daily. It seemed to cause the subsidence of pain and uneasiness. It likewise produced a certain amount of diaphoresis and diuresis. He brought the remedy before the notice of the society, not as a specific, but as having succeeded with him in several cases. Dr. Simpson of Edinburgh had used it with great benefit in hypochondriasis and debility after parturition.

Dr. Browne asked if it had been employed in chronic as well as acute rheumatism.

Dr. Johnston inquired if it was equally applicable in cases where complication ensued.

Dr. Ferguson entertained great doubts as to the efficacy of specifics generally, and thought that this would probably run the course of such remedies. At the same time, he could not doubt the evidence of the facts laid before the society by Dr. Graves.

{Rough minute book: Dr. S. Reid read the following notes of a case of acute rheumatism ...

Dr. Bryce thought Dr. Reid's case was a most interesting one and one that should excite discussion.

Dr. Johnston noticed the fact of the Edinburgh School not employing mercurials in the cardiac complications of rheumatism.

Dr. Browne thought that the mercurials were greatly abandoned in the treatment of serous inflammation generally.

Dr. Graves thought that while avoiding one extreme we should not fall into the other and that the anti-mercurial feeling should not be pushed too far.

The President treated a case in which KI produced livid discoloration of lips.

Dr. Ferguson thought that the treating of acute rheumatism could not be generalised so. That in some cases mercurials were applicable and in other cases they were not. Some cases required the most active antiphlogistics, others required stimulation and support. Opium he thought protected considerably against the complications.

Dr. Reid stated that Dr. Richardson produced endocarditis at will by injection of lactic acid into the peritoneal cavity, and that thus one had a hint as to the nature of the treatment in acute rheumatism. He found KI beneficial in many cases of cardiac affection where mercury had pushed to the full extent.

Dr. Ferguson said that lemon picric was considered most important in the treatment of acute rheumatism by a large section of the profession. He thought pericarditis more frequent than endo- and he thought the mere presence of a murmur was by no means conclusive in the course of an acute rheumatism of the occurrence of endocarditis. In the latter case he thought it was necessary for some physical obstruction and then he was not sanguine as to the effects of treatment. In such cases he thought that a bruit which came today and went off in a few days was not likely to be produced by a physical cause.

Dr. Browne whether if Dr. Ferguson thought medicines did not limit cardiac lesions—e.g. mercury followed by iodide of potassium just as in lymph on the front surface of the iris.

Dr. Ferguson had great doubts of the removal of lymph from the endocardial lining by any medicines.

Dr. Reid states Dr. Richardson on examination no murmur at first, then found an [?] murmur 4 days after injection of lactic acid. On autopsy found the valves swollen and a deposit of gelatin within pericardial serous membrane. On puncturing the membrane an exudation come out. In such cases medicines might produce absorption.}

Society agenda from Council minute book.

The sixteenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, February 23rd, at three o'clock.

Business.

The President will exhibit and describe a new form of splints for fracture of the radius.

Belfast Clinical and Pathological Society

Eighth Session: 1860–1861

President Alexander Gordon

{Rough minute book:
SEVENTEENTH MEETING.
February 23rd, 1861

The President in the chair. Drs. Ferguson, T. Reade, Cuming, Johnston, D. Moore, Browne, Patterson, Warwick, Dill, Pirrie, O'Brien, W. MacCormac, J. Moore, Murney, Bryce, Thomas Thompson.

The President then exhibited and described a new form of splint for fractures of lower end of radius.

Dr. Browne thought there could be no second opinion of the value of the proposed radial splint. He had himself treated several cases successfully. He thought however that other means would produce the same effect but not with the same ease and satisfaction. He referred to the liability of unstable fractures of lower end of radius for luxation—fall on the palm.

Dr. Johnston referred to the practice of treating the radius which had been practiced in Dublin. He thought Dr. Gordon's paper a most valuable one.

Dr. Browne exhibited a cancerous tumor removed from mamma. The disease was medullary and he thought it likely that it would not be of any benefit to the patient.}

Society agenda from Council minute book.

The seventeenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, March 2nd, at three o'clock.

Business.

Dr. Bryce will exhibit casts of triplets, and give history.

{Rough minute book:
EIGHTEENTH MEETING
March 2nd, 1861

Chair taken by Dr. Patterson, Warwick, D. Moore, Johnston, Aickin, Dill, J. Moore.

Dr. Dill exhibited a uterus containing an enormous tumour, supposes it to be fibro-cystic.

He also exhibited a brain and piece of left lung of a patient admitted into hospital a short time since. The brain showed numerous abscesses.}

Society agenda from Council minute book.

The eighteenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, March 9th, at three o'clock.

Business.

Dr. Bryce will exhibit casts of triplets, and give history of case.

Dr. Dill will exhibit tumor of uterus, and give history of the case. Also a wax model of brain with several abscesses, and give history of the case.

{Rough minute book:
NINETEENTH MEETING
March 9th, 1861

The President in the chair. Drs. Ferguson, Murney, D. Moore, Rea, Dunlop, Mulholland, Dill, W. Mac Cormac, J. Moore, Patterson, S. Reid, Johnston, Cuming.

Dr. Dill exhibited uterus with tumour removed from a patient æt 40, unmarried. Case of hæmorrhage when admitted to hospital. On examination there found to be a large abdominal tumour. The patient when placed in Dr. Dill's hands seemed to be suffering from weakness principally. She was in fact anæmic.

When this tumour was examined it was found to be fibrocystic involving the anterior part of the uterus. The fundus and posterior wall were almost healthy and the ovaries also. The neck and os were ulcerated and from this proceeded the drain on the system which caused the fatal termination, not so much the tumour itself.

Dr. Ferguson asked if the patient had laboured under any affection of the veins or swelling of the lower limbs.

Dr. Dill stated there was none which he ascribed to the fact that the tumour was free in the cavity of the abdomen and not in the pelvis.

Dr. Murney thought the ulcerated action of the os was due to epithelial cancerous action, from the appearance of the one and the fetid nature of the discharge.

Dr. Dill stated in reply to Dr. Moore that the discharge was sometimes ordinary, at other times [?] clotted and even fœtid.

Surgeon Johnston has a dispensary [patient] with aggravated menorrhagia coming off in clots of blood. It is the second case he has seen. The neck and os healthy. Over the vesical region can feel a globular tumour which appears to him to be a uniform enlargement of body of uterus. He found gallic acid to give great relief in staying the discharge.

The President has seen one or 2 cases in which a similar [?] had taken place from the increase of the cavity, probably from the contraction of the neck and os.

Dr. Dill then exhibited a wax cast of abscess of brain occurring in a patient admitted from disease of chest. He recovered from this and was permitted to rise. He

then had a rigor and severe headache. He was blistered and treated with mercurials without any good effect. He then had convulsions and the symptoms continued to aggravate until death.

On opening calvarium sinuses much gorged and on cutting into hemispheres several abscesses were found.

In answer to Dr. Ferguson Dr. Dill said the case lasted 14 days after the 1st rigor.

Dr. Ferguson asked if the paralysis of arm and eyelid left-side were of the ordinary kind and not the spasmodic, or the abscesses were the result of the acute inflammation or a secondary result from deposition of pus in brain substance.

Dr. Reid asked if the lesions of brain might not be result of the disease of lungs.

Dr. Murney who performed the P.M. found the left lung adherent to left nipple for some extent and lung was almost carnified.

Dr. D. Moore stated that for 2 days subsequent to rigor he was perfectly well, and when he was called to him he was in the warm stage of a fit of ague not the cold. The patient had been admitted for pleuritic affection of left side.

Dr. Dill was asked by Dr. J. Moore if the restlessness was of any peculiar form as Dr. M. had seen several cases of rolling motion.

Dr. Ferguson asked if any means could have been employed in such cases. Would bloodletting be of use.

Dr. Cuming thought it possible that the abscesses might be of old standing and ...}

Society agenda from Council minute book.

The nineteenth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, March 16th, at three o'clock.

Business.

Dr. Bryce will exhibit casts of triplets, and give history.

Dr. Moore will exhibit encysted tumor removed from eyelid.

{Rough minute book:
TWENTIETH MEETING
March 16th, 1861

Dr. Patterson V.P. in the chair, present Drs. D. Moore, McLaughlin, Magee, Halliday, S. Reid, Dill, W. MacCormac, Aickin, Johnston, Warwick.

A man æt 42 admitted January 12 under Dr. Drennan's care. On 1st February came under Dr. Dill's care.

On admission he had been given Iod. Pot. with sarzal then Liq. Donovan's and then again Iod Pot and Brand Sol with Antim Tart and baths 65° low diet.

Had this attack of skin disease for 15 weeks which was now quite general. At first it was considered a

case of eczema afterwards psoriasis. 6 weeks treatment cure.

Dr. Magee would not have used low diet. Would have prescribed a [sturaling?] wash [of?] lyttæ, borax, glycerin, rose water.

Dr. Johnston thought it probably a case of eczema more than psoriasis and that you might thus ...

Dr. Halliday considered the addition of the Tart. Ant. to the medicine very judicious and baths with bran and about 3oz Carb Pot formed a very excellent application.

Dr. Bryce brought forward case of triplets. Two were small and each of them $\frac{1}{4}$ the size of the 3rd. They were about 5 or 6 months. A very large quantity of water came away with the 1st. With the 2nd none. With the 3rd a very large quantity of water came away.

Dr. Aickin remembered a case where there was a very large quantity of water, a large child. He thought the large quantity in Dr. Bryce's case had exerted a pressure on the umbilical by one fœtus in distinction to the others.

Surgeon Johnston mentioned a case under his treatment which had been operated on for cancer 7 weeks since in which the cicatrix had not healed and the disease was rapidly returning with enlarged glands in axilla.}

Society agenda from Council minute book.

The twentieth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, March 23rd, at three o'clock.

Business.

Dr. Moore will exhibit encysted tumor removed from eyelid.

Dr. Browne will notice successful cases of Wurtzer's operation for reducible hernia.

Dr. W. MacCormac will exhibit a patient affected with an unusual form of skin disease.

Dr. S. Reade will read notes of a case of Addison's disease.

{Rough minute book:
TWENTY-FIRST MEETING
March 23rd, 1861

Professor Reid in the chair, present Drs. Bryce, J. Moore, D. Moore, Murney, Magee, Cuming, Ferguson, Halliday, Dill, Murray, W. MacCormac, Browne, Mulholland, Patterson.

Dr. W. MacCormac ...

Dr. Halliday said he had a similar case under treatment.

Dr. Browne had seen the case and given sol. Donovan and glycerine with T. Iodine.

A lengthened discussion took place on the application of T. Iodide and the question of its production of pain.

Dr. J. Moore then exhibited a tumour which he had removed from the upper eyelid.

A tumour which was the size of a Spanish chestnut conjunctal in a lady of 28. Cut down on it and found the cyst very thin, the envelope of a turkey's egg. When the dissection was nearly completed a small cut was made into the tumour with escape of a portion of contents. It was necessary to open the sac completely, pass in the finger and finish the dissection with it. The contents were of the consistency of cream changed and filled with hairs and on fully extracting the sac the lining membranes there were hairs growing. The wound healed by the 1st intent.

Dr. Bryce had a case in which there was a mass of hair discharged from an abscess on the scalp.

Dr. Murney thought it would be interesting to know if the hairs contained a central canal.

Dr. Dill inquired if injection and evacuation of sac ever effected a cure in cases of cystic tumour.

Dr. Moore thought in this case such treatment would be of no avail.

Dr. Murney stated with regard to Dr. D. brain that there was no abscess in cerebellum on P.M. and the abscess in hemispheres was in upper part of hemispheres.

There was no evidence of phlebitis Dr. M. said in answer to Professor Reid.

Dr. Moore exhibited a thumb removed after mutilation in a straw cutter. The palm is somewhat mutilated. Dr. Moore however found tetanus. The thumb was very much lacerated.

Dr. Browne brought forward Wurtzer's cases.¹

Dr. Murney gave an explanation of the way in which the mechanical appliance acted. In Dr. Murney's case there was complete adhesion of the invaginated skin which would he thought be desirable to strengthen the abdominal parietes. Now no external sign of the operation remains.

Dr. Moore's case he kept the plug in for six days. The invaginated portion of skin remains plugged up and appears to be no probability of the descent of the gut.

Dr. Dill asked if there was hernia on P.M. in any of these cases.}

¹ [Wurtzer invented an instrument for the treatment of hernia which invaginated a portion of skin and fascia and held it there until inflammation united the invaginated portions. Ref. Greenville Dowell, *Treatise on Hernia*, 1876, Philadelphia, p38.]

Society agenda from Council minute book.

The twenty-first meeting of the Session will be held in the Museum of the General Hospital, on Saturday, March 30th, at three o'clock.

Business.

Dr. S. Reade will read notes of a case of Addison's disease.

{Rough minute book:
TWENTY-SECOND MEETING
March 30th, 1861

The President in the chair, present, Dr. D. Moore, Dr. W. MacCormac, Ferguson, Browne, Patterson, Dill, Mulholland, S. Reid, J. Moore, Rea, Warwick, Johnston.

Professor Ferguson brought before the Society for discussion the question of the present asthenic character of disease.

In some cases of pneumonia with solidification lately he had given up reflecting measures such as tartar emetic and administrated wine.

Dr. Browne agreed with Professor Ferguson and thought that surgical as well as medical cases exhibited a similar tendency.

With regard to the hospital gangrene which recently took place in the house the President thought it arose from local causes, although he thought it worthy of note that there had been previously puerperal fever in the house.

Surgeon Johnston mentioned possibly as a coincidence the fatal occurrence of convulsions with whooping cough arising without any premonitory symptoms such as vomiting. Treatment seemed to have no effect.

Dr. Moore exhibited a girl with a large polypoid growth in the ear.

Dr. Browne mentioned that it was not always safe to remove these polypi for when the origin of the growth is from the internal ear the sequel of meningitis may arise.

Active hæmorrhage frequently takes place, and the restoration of hearing is not general.}

Society agenda from Council minute book.

The twenty-second meeting of the Session will be held in the Museum of the General Hospital, on Saturday, April 6th, at three o'clock.

Business.

Professor Reid will read notes of a case of Addison's disease, with morbid representations.

{Rough minute book:
TWENTY-THIRD MEETING
April 6th, 1861

Dr. Patterson V.P. in the chair, Drs. Reid, Ferguson, Mulholland, Murney, Thompson, D. Moore, W. Mac-Cormac, Rea, Johnston, Dill, J. Moore, Browne, Murray, Warwick, Bryce.

Professor Reid then read notes of a case of Addison's disease.

Surgeon Johnston described a case which he had had some years since in which the symptoms, coloration of skin, intense debility, from which the patient sank, lead him now to consider that it was a case of Addison's disease.

Professor Ferguson asked the connection between the suprarenal lesions and the color of skin. Brown-Séquard thinks that the suprarenal capsules have an influence on the elimination of pigment.

Dr. Drennan referred to Dr. Laycock's theory on coloration of skin and to the frequent instances in which this peculiar color exists with no suprarenal lesion.}

Society agenda from Council minute book.

The twenty-third meeting of the Session will be held in the Museum of the General Hospital, on Saturday, April 13th, at three o'clock.

Business.

Professor Reid will read notes of intra-thoracic tumor, with history of patient.

Dr. Moore will describe an affection of the testicle.

Dr. Browne will exhibit limb removed for extensive necrosis of bone.

Professor Gordon will exhibit limb removed for compound fracture.

{Rough minute book:
TWENTY-FOURTH MEETING
April 13th, 1861

Dr. Patterson in chair, Drs. Browne, C. Ferguson, T. Reade, S. Reid, Mulholland, Dill, D. Moore, Aickin, Johnston, Warwick.

Professor Reid read notes of a case of intra-thoracic tumour. Exhibited morbid parts.

Dr. Ferguson thinks that the absence of external tumour renders it very difficult of diagnosis.

Dr. Murney apology for Dr. Scott who had to leave town on business.

Dr. Warwick exhibited contents of tumour removed from forehead of girl 23 or 24 years of age. Sebaceous

secretion, about size of large hen egg. Did not remove sheath.

Dr. [T.?] Reid considered it an ordinary wen.

Dr. Moore exhibited polypus of ear, in girl æt. 12.}

Council 24th Meeting of Council, April 17th 1861.

Present, Dr. Patterson in chair Drs. Drennan, Dill, Mulholland, Aickin.

Resolution. Proposed by Dr. Patterson, seconded by Dr. Mulholland and passed "That rule 23rd be left out for the election of the office-bearers."

Ballot papers to be issued as soon as possible with the list of attendances of members of the different meetings.

{Rough minute book:
TWENTY-FIFTH MEETING
April 20th, 1861

President in chair. Professor Ferguson, Reid, Drs. Dill, D. Moore, S. Browne, Patterson, Cuming, Aickin, Bryce, Halliday, Johnston.

Dr. Browne exhibited parts residuum of surfaces of knee joint.

Also exhibited leg removed for extensive necrosis.

Also exhibited leg amputated for extensive gangrenous sloughing from accident.

Dr. Bryce asked

President. 5th cases operated in this hospital.

Operated on case of pulpy degeneration as well for 9 [cases?] but turned out ...

This scrofulous is a proper case to operate on especially when confined to articular surfaces, the constitutional symptoms are not so serious in the latter.

Remarked with respect to 3rd case ...

President exhibited leg removed from old man, 77 years, [?] [?] amputated [?] after accident. Today is 10th day after operation, doing well.

Professor Reid exhibited morbid parts and read notes of case of disease of kidneys and bladder.

Professor Ferguson mentioned had seen a case of catalepsy.

President remarked a case where friction bands after accident in a mill. Reoperated and disease in edges.

The Annual Meeting will take place at Three o'clock, on
Saturday, May 4th.

Council 25th Meeting of Council [probably on 24th April 1861]

Dr. Patterson, Mulholland, Aickin.

The President and Secretary to attend on Friday evening to make up number and lock up the ballot box.

Society agenda from Council minute book.

The twenty-fifth meeting of the Session will be held in the Museum of the General Hospital, on Saturday, April 27th, at three o'clock.

Business.

Dr. Moore will describe an affection of the testicle.

Dr. Browne will exhibit necrosed femur, and describe the case, requiring amputation.

Professor Ferguson will read notes of a case of intestinal calculus, and exhibit specimen.

{Rough minute book:
TWENTY-SIXTH MEETING
April 27th, 1861

President in chair, Patterson, Cuming, D. Moore, Bryce, Professor Reid, Murray, Rea, Mulholland, Dill, Patterson, Warwick, Aickin, J. Moore, Professor Ferguson.

Professor Reid moved and Dr. Dill seconded "That the time of receiving the ballot papers be extended to 6 P.M. on Friday 3rd May and that a circular be issued to that effect."

The President read notes of case of necrosis of femur for Dr. Browne and exhibited limb removed.

Dr. Dill exhibited and described post-mortem appearances of brain on woman who died in hospital, disease apoplexy. There is a large coagulum in the left ventricle. The origin of the hemorrhage is from the corpus striatum.

Professor Ferguson thought it was rare to see such extensive hemorrhage in a patient living 15 hours.

Professor Ferguson exhibited biliary concretions and read notes of case.

Dr. Cuming had examined the specimen chemically. Considered it of the same composition as ordinary biliary gall stone.

President. Calculus passes the duct but very slowly. Death may occur in the process.

Dr. J. Moore described and showed drawing of disease of testicle.

Professor acute meningitis.}

Special Council Meeting to be called before the annual meeting at 1½ P.M. Saturday May 4th for counting of papers &c.

Notice of the Annual General Meeting in the Eighth Session.

CLINICAL AND PATHOLOGICAL SOCIETY.

General Hospital,
May 3rd, 1861.

Sir

We beg to inform you that the Annual Meeting of the Society will be held in the Museum of the General Hospital, on To-morrow, May 4th, at Three o'clock, to receive—

1. Report of Council.
2. Report of Auditors.
3. Announcement of New Office-bearers.
4. Closing Address of President.
5. President Elect.

N.B.—The Treasurer, Dr. Halliday, requests all Members who have not yet paid their Subscriptions to forward them immediately.

We are Sir,
Your obedient Servants,
William Mac Cormac, A.M., M.D.,
William Aickin, M.D.,
Honorary Secretaries.

Council May 4th 1861, 1½ P.M., Special Council Meeting for counting of ballot papers &c.

Present, the President in the chair, Drs. Patterson, Professor Reid, Pirrie, Bryce, Dill, Corry, Halliday, Aickin.

The ballot box contained 31 papers which was the number received up to the hour of _ the previous evening at which time the Secretary of Council secured the box and delivered the key to the President.

One of the ballot papers was from Dr. Babington, Londonderry, who declined to vote as he did not intend continuing a member of the Society. The counting of the remaining 30 was proceeded with and results as follows.

Officers for the session 1861 & 2.

Ex-President,	Professor Gordon.
President,	H. Murney Esq., M.D., J.P.
Vice-Presidents, Town	Dr. Patterson.
	Pirrie,
	Browne,
Country	Graves, Dublin ¹
	Browne, Derry,
	Dunlop, Holywood.

¹ [Probably Cookstown is meant.]

ANNUAL GENERAL MEETING

May 4th, 1861

President in chair, Dill, Patterson, J. Moore, Johnston, Professor Ferguson, Cuming, D. Moore, Pirrie, Murray, Warwick, Bryce, Stewart, Mulholland, Aickin.

After the minutes of the last meeting were signed the minutes of the last annual meeting were also read and signed.

Report of Council ...

Report of Auditors ...

Announcement of Office Bearers ...

Secretaries and Treasurer ...

President regretted his inability to attend regularly.

Professor Ferguson was moved to chair.

Dr. Stewart moved a vote of thanks to the retiring President requesting him to still take the same interest in the [Society]. Seconded by Dr. Patterson passed unanimously.

Professor Gordon returned thanks.}

Belfast Clinical and Pathological Society

Ninth Session: 1861–1862

President Henry Murney

BELFAST CLINICAL
AND PATHOLOGICAL SOCIETY

NINTH SESSION
1861–1862

President HENRY MURNEY, M.D., Surgeon to Belfast
General Hospital; formerly Demonstrator of Anatomy
Queen's College, &c., &c.

FIRST MEETING
October 26th, 1861.

Case of Cataract.

Dr. BROWNE introduced a young girl, aged 14, from
the country, labouring under cataract in both eyes.

He observed, that the case before the Society pre-
sented the usual appearance of congenital cataract,
though the patient, up till two years ago, had enjoyed
good sight; since that time the powers of vision had
gradually declined, until now she could merely distin-
guish the outline of large objects, even when the
pupils were fully dilated.

No cause whatever could be assigned for the
occurrence of the disease, as there had not been any
injury or previous affection of the eyes. In his opinion
it was the result of slow inflammation, and the con-
sequent arrest of nutrition, just as, he believed,
occurred in congenital cataract, either in utero or
very soon after birth. Certainly it was very rare, he
said, to see cataract occurring, as this had done, in a
perfectly healthy young person, and where there had
not been injury.

The operation he designed was that for breaking
up and absorption—improperly called the operation
for solution. He observed, that the needle—a very fine
one—should be introduced through the cornea, and
the capsule of the lens should be only slightly torn in
the first operation, lest inflammation should be set
up.

In the future operation or operations the needle
could be more freely used with comparative safety.
Some weeks should intervene between the opera-
tions; indeed the needle should be only used afresh
when absorption or the disintegration and disappear-
ance of the cataract seemed at a stand still.

SECOND MEETING
November 2nd, 1861.

Dr. BROWNE exhibited a patient labouring under *trau-
matic cataract*. The capsule had been wounded by a
blow from a hackle-pin; and spontaneous cure was
now going on by absorption.

THIRD MEETING
November 9th, 1861

Case of Enchondroma of Hand.

Dr. BROWNE presented the model of a hand, taken in
plaster, and also the morbid specimen which he had
recently amputated for enchondroma.

The patient was a woman, aged 64 years, from the
country, near Belfast. She stated, that some 16 years
since she had observed a small swelling close to the
head of the metacarpal bone of great finger. This, she
says, was entirely dispersed by treatment. Within the
last two years, however, it had returned, and the
swelling extended rapidly from that point to the rest
of the hand, involving the metacarpal bones and the
phalanges, with the exception of the distal phalanges
of the thumb and little finger. The principal enlarge-
ment was on the back of the hand, where the tumour
presented a somewhat unequal, glistening surface,
the veins at some parts being tortuous, full, and
enlarged. This tumour was elastic; and, at one or two
places, there was a sensation of fluid beneath the
touch. She came into hospital on the 4th; and on the
10th. of September the hand was amputated three
inches above the wrist joint, by the double flap of the
integument and circular of the muscular structure.
The stump, an excellent one, healed up kindly. Six
weeks after the operation he saw the patient in excel-
lent health. Indeed her health had not suffered much
before, as she had not had very much pain—only neu-
ralgic uneasiness arising from pressure upon the
nerves.

On making a section of the tumour, and dissecting
back the integuments, there was a very thin shell of
soft bony structure, then cartilaginous structure con-
taining gelatinous matter in cells. This portion very
closely resembled boiled sago mixed with red wine.
The entire normal structures of the entire hand had
been destroyed. The metacarpal bones of the thumb
and little finger were flattened, and changing into
cartilage, the osseous structure having nearly disap-
peared.

Though the age of the patient, the rapidity of the
growth, and resemblance of some parts of the mass to
colloid cancer, might raise a doubt as to the true
nature of the growth, he still thought the case one of
enchondroma, rapidly degenerating—doubtless a rare
affection, and not one of malignant disease.

FIFTH MEETING
November 23rd, 1861.

Fracture of Clavicle.

Professor GORDON exhibited a patient who had sus-
tained a fracture of the clavicle at the junction of the
outer with the two inner thirds. The outer fragment

had undergone the usual displacement, inwards and downwards. He has maintained, for some time past, that in fracture of the clavicle the shoulder is elevated, instead of being depressed. In the treatment of this accident he does not push the shoulder upwards and backwards, as usually recommended, but depresses it. He places a very large pad over the lower part of the side of the thorax; along the arm and forearm an angular splint, well padded above, where it rests against the biceps muscle, and extending from the anterior border of the axilla to the hand. The lower part of arm and inner surface of elbow is then firmly bandaged to the large pad. The elbow joint being thus fixed, and rendered incapable of flexion by the splint, he next elevates the forearm at the wrist, by a sling, which passed round the neck; and by so doing the shoulder is depressed and pushed outwards. In the present case this apparatus has succeeded admirably in maintaining accurate apposition of the fragments. It is simple in construction, easily applied, and not liable to become disarranged.

Professor GORDON introduced a patient whom he was treating for *comminuted fracture of the clavicle*.

The PRESIDENT then read his opening address which had been deferred until this date owing to his unavoidable absence.

On the Statistics of the Mortality of Fractures of the Skull; Effects of Operation, &c., &c.

I HAVE frequently noticed there is a tendency to class all fractures of the skull together, and to look upon the patient's prospect as little short of hopeless. Serious as the mortality is, I did not think an examination of statistics would show so many sufferers rescued from death.

I would here observe that, as a rule, I look with great caution on statistical tables, knowing how frequently cases are classed together because of some trifling point of resemblance, although they may differ in most important particulars; and also, that it is much more likely a man would publish a successful than a fatal case, not that any desire to mislead or give a false idea of the mortality of a disease might exist; but when, from the serious character of the affection, it was expected the tendency would be to death, a sense of satisfaction, perhaps a lurking one of pride, that, contrary to all anticipations, recovery ensued, might tempt him to place on record that which probably he would not have done if the prognosis had been verified. Grave objections, no doubt; but, on the other hand, I may say, for some time past, our Medical Journals have contained records of all the most serious cases, with operations performed, in the London and principal Provincial Hospitals in England, we are thus likely to obtain an account of all unsuccessful as well as successful cases, and will be enabled to

approximate the mortality of many injuries not yet precisely defined. I would add my belief that, from the fatal character of fractures of the skull, surgeons hesitate less about the publication of the cases than in many other affections requiring interference. These reasons I consider are sufficient to warrant a greater degree of confidence than is usually reposed in statistical tables, and I make use of them as giving by figures an approach to the mortality, effects of operation, &c., &c., and some other particulars in this class of affection.

I have records of several cases of fractures of the head which have come under my notice, I shall take the liberty of referring to a few of them where I find they illustrate portions of the subject. My information is not so accurate on some points as I could wish: for instance, in fracture of the base, the reporter frequently mentions that fact without specifying the part of the skull involved; and in injury of the superior region of the head, the calvaria is named without specifying the bone or bones injured.

I have taken a period of 10 years, from 1851 to 1860, inclusive, and have tabulated the cases of fractures of the skull to the number of 253, which appear in the following Journals:—*Times and Gazette; Lancet; Dublin Medical Press; Dublin Hospital Gazette; Edinburgh Monthly Journal; Dublin Quarterly; Guy's Hospital Reports; and the Trans. Belfast Clin. & Path. Soc.* I have also examined *Braithwaite's Retrospect*, and the *British and Foreign Medico Chirurgical Review*. I had not access to other Journals. Twenty five cases were treated by practitioners not attached to public institutions; all the others were contributed by the attendants on the large metropolitan and provincial institutions, or by medical officers in the public service.

Of course I shall follow the usual division of the subject, viz.:—Fractures involving the calvaria or lateral parts of the head, and fractures of the base; and first of the former:—In addition to cases I have treated myself, I have the particulars of 187. In 84 of these the fracture was situated in one of the parietal bones; in 57 the frontal; in 9 the occipital; and in 37, two bones of the calvaria or lateral regions of the head were implicated, or the precise part of the skull-cap was not specified.

The mortality in these several localities was as follows:—most serious of the last mentioned—out of 37 cases, 22 died; then in fractures of the occiput—of 9 cases, 5 died; next we have injury to the frontal bone—of 57, 25 died, and one remained under treatment. Fractures of the parietal bones were most numerous and least fatal, as of 84 cases, 34 died, and one remained under treatment. As a summary we have 86 deaths; 99 recoveries; and two undisposed of, in a total of 187 cases, being 46 per cent. of deaths. A question has occasionally arisen, which are the most fatal fractures of the superior region of the head? The

above shows that injuries to the posterior region are most, and to the superior least dangerous; and that fractures of the frontal occupy the middle place in danger as in frequency.

Of the 187 cases the bone was depressed in 149. Should the bone be elevated in every such case? should elevation be performed on the occurrence of reaction, whether symptoms of compression are present or not? or would the prospect be more satisfactory by delaying till well marked signs of pressure are exhibited? does the age of the patient modify in any way our opinion?

On reference to some of the older writers, as Pott and O'Halloran, we find that every case of fracture, with depression, was considered fit for the trepan. In the introductory observations to his work on injuries of the head, published in 1793, the latter writer lets us know, in his quaint style, how frequently he was called on to perform this operation, he writes:—"I have had no less than four fractured skulls to trepan on a May morning, and frequently one or two. In the course of above thirty-five years practice, I may safely affirm, because truly, that on an average, one month with another, from three to four cases have fallen to my share, of either fractures, concussions of the brain, or extravasations."¹ Again he says, "Every fracture with depression necessarily demands the operation; and though some particular cases may be adduced, when nature has somehow or other brought about the business of healing, yet it is by no means to be trusted to; and the surgeon is inexcusable who fails to attempt, at least to propose and press it. Simple fractures of the cranium, with depression, when relieved on the spot, or in the space of two or three days, almost always terminate happily. In the course of more than 200 accidents of this simple kind, I cannot recollect a failure in a single instance."

"Fractures without depression do not demand operation."² Pott considers all depressed fractures require operation; and nearly all undepressed, also require the interference of the surgeon. He says, "perforation is absolutely necessary in seven cases out of ten, of simple undepressed fractures of the skull. Let us for a moment inquire why it is so. The reasons for trepanning in these cases are, first, the immediate relief of present symptoms arising from pressure of extravasated fluid; or second, the discharge of matter formed between the skull and dura mater, in consequence of inflammation; or third, the prevention of such mischief as experience has shown, may, most probably, be expected from such kind of violence offered to the last mentioned membrane. These are the only reasons that can be given for perforating the skull in the case of an undepressed fracture; and very

good and very justifiable reasons they are, but not drawn from the fracture."¹

In another place he says, "I have no doubt that although by establishing it as a general rule, to perforate in all cases, some few would now and then be subject to the operation, who might have done very well without it; yet, by the same practice, many a valuable life would be preserved, which must inevitably be lost without it, there being no degree of comparison between the good to be derived from it when used early as a preventative, and what may be expected if it be deferred till an inflammation of the dura mater, and a symptomatic fever make it necessary."²

I find elevation of depressed bone was practised in 124 of the cases I have tabulated, of these 60 died; 62 recovered; and 2 remained under treatment; as nearly as possible the deaths were 50 per cent.

In 25 cases of fracture with depression, no operation was performed. On analysis of the symptoms of those who recovered—one had profound insensibility; another was insensible and convulsed; another had partial paralysis; the remainder were partially insensible, or had threatened inflammation in the head. Of those who died the symptoms recorded are:—insensibility in one; paralysis in another; epileptic fits in a third; (I use the expressions of the reporters,) 7 died; 18 recovered: being a mortality of 28 per cent.

Some interesting Cases of Fracture of the Calvaria with Depression, have come under my observation in hospital:—

A lad 16 years of age, while engaged at work in one of the ship yards, received a blow on the side of the head from a heavy piece of timber which had fallen a height of 10 or 12 feet; when brought to hospital we were informed he had vomited a large quantity of blood; he laboured under collapse first, then concussion; on careful examination of the head (there was no scalp wound,) a fissure extended from the left parietal protuberance forwards for about one and a half inch, bifurcated, producing the shape of the letter Y; the piece of bone between the limbs of the letter, and also, one margin of the fissure, in its posterior part, were depressed, I would say rather more than the thickness of a half-crown. The symptoms of concussion yielded after a time, and were followed by cerebral irritation, and inflammation of a not very intense form. When convalescent I felt dissatisfied with his stolid stupid manner, but learned from his friends he was of a sulky disposition, and that his mind and character were as before the accident. The treatment adopted was cold applied to the head, mercury in small doses, until the constitutional effect was produced, and when necessary, purgatives.

² Page 111.

In this case, from the vomiting of blood, I feared more serious mischief than the fissure of a small portion of bone. The possibilities of fractured base, or of injury to the liver, or some important abdominal organ, suggested themselves; but when hours passed by and full reaction was established without its recurrence, my attention was fully turned to the concussion; as it subsided from the depression of bone, I looked for the appearance of symptoms of compression—had such manifested themselves, I would have cut down and raised the bone.

A few days after the admission of the last, a boy, aged 13 years, came under treatment. Two evenings previously, while seeking for a ball, he had fallen from a man's shoulders and alighted on his head; he is reported to have been insensible for a short time, and on recovery to have vomited repeatedly, and complained of pain in the part injured, with general headache and sickness of stomach. On admission the head was shaved, no wound or abrasion was visible, but a fissure of the skull, as in the other case, was felt, extending from the left parietal protuberance forwards almost to the anterior border of the bone; the upper margin of this was depressed to about the same extent as in the other case.

I placed him on low diet, gave him some alterative doses of mercury, and kept him in hospital for a time.

Here we have one of those most infrequent cases—a grave injury followed by most trifling constitutional disturbance; in fact, from the time he came under my care he was well—all headache, &c., &c., had passed off. My treatment was merely precautionary.

Again, about a week later, a fine boy, about eight years old, was brought to hospital—a log of timber had fallen on him, fracturing the right forearm very severely, and causing a wound which commenced at the right frontal protuberance and stretched upwards and backwards about four and a-half inches in length; the scalp was separated to a considerable extent, and a fracture, parallel to the wound, occupied fully three inches of the frontal and a small portion of the parietal bones; there was depression to fully the thickness of the skull. In the unavoidable absence of my colleague on duty, I saw him about an hour after admission. Bodily warmth was then restored, his pulse and respiration were slow; pupils dilated, uninfluenced by light; he lay quietly, head resting on the right (the injured) side; when turned on the left side he gave a fretful cry and endeavoured to replace it; by sharp speaking or pinching he could be partially aroused—give a monosyllabic answer, and then sink back into insensibility. The house surgeon informed me, half an hour before my visit he could be roused with much greater facility, when he gave his name, residence, &c., &c. That I might have an opportunity of noting the increase of the coma, I deferred operative interference for an hour, when I returned and examined

him, and was satisfied the insensibility was greater than before.

I then had him removed to the theatre for the purpose of operation; immediately before commencing, I again essayed to arouse him, when suddenly he opened his eyes and answered quite collectedly, although slowly and rather stupidly. Under these circumstances I did not deem it necessary to raise the depressed bone.

The boy passed to the care of my colleague; he laboured under concussion for a time, and gradually recovered. He was discharged in seven weeks.

This was to me a most interesting case; had the profound insensibility, which was twice so marked, continued, my treatment would have been elevation of the bone with Hey's saw, if possible, if not, by the trephine first, then the saw. The occurrence of insensibility, followed by a state from which he could be aroused, I believe, was due to cerebral congestion, for, after severe injury the circulation is embarrassed and imperfectly performed; and, I have several times noticed, although not so well marked as in this case, the insensibility sometimes more, sometimes less profound, without any apparent cause.

Ten months ago, a boy, 16 years of age, fell a height of 12 feet in the hold of a ship on Queen's Island, he alighted on the posterior part of his vertex. I was in the hospital on his admission, and was informed that he was insensible for a period of about 10 minutes after the accident, but from the time he was placed in the ferry boat until his arrival here, he was perfectly collected. There was a wound one and a-half inch long, situated over the upper part of the occipital bone; almost at the summit of that bone a V shaped fracture was seen, the point directed upwards; the limbs were each about one inch long; the bone was depressed fully the thickness of two half-crowns; he merely laboured under collapse, and was quite astonished when I ordered him to bed. The wound healed up, and he was discharged in a month.

I saw him six months afterwards, he had not experienced the slightest bad effects from the fracture.

This is another example of a most serious injury without the appearance of a single bad effect—in fact, so well did he feel, I had considerable difficulty in keeping him in hospital for a reasonable time.

Is the danger to the patient increased by cutting down to make an examination merely of the site of fracture—by, in fact, rendering the fracture which was simple, compound? Most surgeons are opposed to this treatment, Sir Astley Cooper, in his forcible language, says, "the man who would do so should be cut for the simples." Mr. Guthrie and others do not consider the patient's danger is in any way increased by it.

I believe the principal advantage to be attained by it is, that we can ascertain more accurately the extent

to which the cranium may be fissured, and the amount of depression of the outer table; also, if death of a piece of bone is about to take place we are made cognizant of the fact at an early period by its altered appearance. Although I would not practice it heedlessly, or without due consideration, I should have no hesitation in cutting down, provided I was uncertain as to the extent or amount of the depression of bone.

Of fractures without depression we have reports of 38 cases, of which number 25 were subjected to operation and 13 were not; of the former 13 died, 12 recovered; of the latter 5 died, 8 recovered. Among those subjected to operation, we have 3 cases of paralysis; 5 more or less convulsed or with epileptiform fits; 4 insensible; 3 of compression; 3 of encephalic inflammation; and, what I consider strange, 5 are marked as labouring under very slight symptoms or none at all. Those not submitted to operation suffered from slight concussion, collapse, effects of shock, &c., &c. One, a recovery, had epileptic fits.

In December, 1858, I brought before the notice of the Belfast Clinical and Pathological Society, some cases of fracture of the skull. One was a patient with fissure of the frontal bone. In giving a brief account of his case, I stated, he laboured under paralysis which gradually became general. Under treatment this slowly passed off, and he was discharged from hospital quite restored.

Twelve months after, this man came under the care of one of my colleagues, he had fallen into a vat of boiling ley in a bleaching establishment. He told me he had enjoyed excellent health since his dismissal; he had not suffered from headache, loss of power, or any effect of his injury. In a few days after his second admission he was attacked with tetanus, and died. I made an examination of the head and removed the portion of the calvaria which had been fractured, and which was completely united. The dura mater was most intimately adherent to the bone in the vicinity of the fractured part. The brain, &c., &c., were perfectly normal.

A man, aged 22, had the upper part of his occipital bone fractured by a heavy piece of iron falling on him, from a height of 12 or 14 feet. When admitted he laboured under the ordinary symptoms of collapse; then well marked concussion. The fissure of the bone could be readily detected at the bottom of an extensive wound. There was no depression. In a month he was discharged from hospital perfectly well. The case was an average one, without the appearance of a single peculiar or anomalous symptom.

Thirty-four cases with depressed bone, although not labouring under symptoms of compression, were operated on; of these, 22 recovered, 12 died. As many of the contributors do not mention the symptoms (if any) which existed before operation, I have no doubt, this series should be much greater. I have, however,

merely tabulated those in which the writer distinctly records the absence of compression.

I must confess my inability to understand the indication for the use of the trephine or saw, where the report states the patient was "sensible" or had no symptoms of compression. And, although I find this practice has been followed by some surgeons, I would not pursue it, therefore, cannot commend it. I consider, at all times, even in the hands of the most skilful, the use of the trephine must expose the patient to considerable risk of encephalic inflammation, and, that we are not justified in operating as a mere precautionary measure, but only in those cases, in which, from symptoms of compression, we have reason to believe there is pressure on the brain which may be relieved by interference.

There may be an exception to this rule, as occurs frequently in military practice, a bullet producing what might be styled an indented or stellate fracture; or in civil practice, a blow from the sharp angle of a brick or slate, driving in the outer table and breaking the inner to a greater extent. Here we might expect pressure on the brain or more extensive laceration of the membranes than the slightly depressed condition of the outer table would indicate; in such a case the appearance of less urgent symptoms, as convulsive twitchings, epileptiform seizures, would be a sufficient warrant for the use of the trephine.

I may here appropriately refer to the question of the frangibility of the tables of the skull. For many years my anatomical experience made me look with considerable doubt on the generally received opinion, that the inner table is so much more easily fractured than the outer. I often observed, if great violence be applied to a skull-cap, the tables would be fractured to about the same extent. In 1858, in a most valuable series of lectures, delivered in the College of Surgeons, England, Mr. Prescott Hewett, not only noticed this, but carried his observations further, he found where violence is applied from within outwards, the outer table is usually injured more extensively than the inner—if from without inwards, the reverse; where great force is used, both will be broken to about the same extent. On reading his remarks I tried these experiments repeatedly, and believe his statements are correct. If, then, an individual has fallen from a great height, alighting on his head, or has received a fracture in some other way, from great violence, I would anticipate the tables of his skull would be broken to the same, or nearly the same extent, but, if a less force were applied to a small surface, I would dread splintering of the inner table.

Another question of interest is that of injury to the brain. We all know the prospect is much brighter where bone is merely depressed without lacerating the dura mater; and injury to that membrane is less fatal than where some of the cerebral texture is torn,

and possibly protruding from the wound. Some of the most experienced surgical writers look upon this latter form of injury as almost necessarily fatal—the mortality is very large—and yet many recover. I have made a distinction between protrusion of the brain and hernia cerebri, as it is at times called, on the one hand, and simple wound or laceration on the other. Where wound of brain has terminated in hernia, I have placed the case under the former head.

Of cases styled protrusion or hernia, there were 35 reported—17 died, 18 recovered. Of wound or laceration, 27 cases—18 died, 9 recovered; total, 62 cases, with 35 deaths. Of these, 9 had more or less of paralysis or convulsive twitchings; 7 symptoms of inflammation of varying degrees of intensity; 9 compression, the majority well marked, although some were not very profound. Then we have concussion, collapse, and shock; several described as not labouring under any symptoms; and some, in which the reporter mentions many of the leading features, but does not state this particular.

On looking at the mortality as it occurred at the different periods of life, we find up to the age of 10 years, inclusive, there were 24 cases with 9 deaths; between 10 and 20, 49 fractures, with 16 of a mortality; from 30 to 40, 86 cases, 48 fatal; and from 40 to 60, 24 with 10 deaths; two had not terminated when their reports appeared.

I do not consider it necessary to give an analysis of the plans of treatment pursued. In a considerable proportion indeed, the writers seem to have considered the indications so obvious, as not to have recorded it at length.

I would merely observe, venesection was practised in 24 cases only. A marked contrast to the custom of the older writers, and also to the injunctions of many within a very recent period. Tartrate of antimony also seemed to be at a discount, for I find it was used in three instances only. The preparations of mercury were most generally employed, in some, merely as purgatives, in a considerable number until the constitutional effect was produced.

I would briefly sum up my views of fractures of the calvaria. The most dangerous are those of the occipital; the frontal next in order; the parietal least so.

The mortality in fissure of the calvaria and depressed fracture is nearly equal, considering all the cases. But take all the cases, whether depressed or not, in which operation was performed, the death rate was 50 per cent. All the cases where no operation was performed, the per-centage was about 34; or if we contrast those cases in which there was depression but no operation, the mortality was 28 per cent.; with those also depressed and operated on without any symptoms, the deaths were 36 per cent. These facts must, I consider, point to the conclusion, that operative measures should only be used as a *dernier ressort*.

The cases of fracture without depression subject to operation, showed a mortality of 52 per cent. Similar cases not operated on, presented 33 per cent. of deaths. In cases of injury to the brain, the mortality was about 43 per cent. Operation is fully warranted when the injury is of the indented class already referred to.

In simple fracture, where there exists a doubt as to the extent of the depression, I consider the surgeon adds extremely little, if anything, to the risk of his patient by cutting down. Fractures are borne with greatest immunity in the first and second decennial periods. The danger to life is greatly increased in the third and fourth, and again diminished in the fifth and sixth periods. I have given a brief report of six cases of fracture of the calvaria with recovery in each. In two of these the occipital—in two the parietal—and in one the frontal were broken—and in one case the frontal and parietal were both involved.

I have examined the reports of 66 cases of fracture of the base of the skull. Of this number, 46 died, 20 were restored; about 69 per cent., an enormous death rate.

When we consider the great injury inflicted on parts so nigh to the most essential portions of the nervous system, generally themselves sufferers from laceration or extravasation, and the uncertainty which surrounds the recognition of these fractures during life, we need not feel surprise at the short list of authenticated recoveries.

In those injuries hitherto considered we had, generally, *tangible* and frequently *visual* evidence of their existence. In the present class, during life, in many cases we are dependent for our prognosis on symptoms which bear no proportion to the amount of fracture sustained.

As an illustration, I would mention the following:—Within half an hour of the admission of the boy with compound fracture of the frontal and parietal bones, whose case I have related just now, a man, aged 60, was also admitted to hospital. While engaged white-washing a house, on a ladder about 20 feet high, a sudden gust of wind precipitated him to the ground. When I saw him about half an hour after admission, the surface was cool, not cold; he was *perfectly* collected; described how he had been engaged before his fall; said he was insensible until shortly before his admission; complained of pain across the temples. I noticed he was somewhat (a little) deaf; I asked was this the result of his injury, he stated he had been deaf for many years—he had bled from the right ear; but when I visited him within an hour of the accident the hemorrhage had ceased, and there was a little dried encrusted blood in the meatus externus.

Immediately after leaving the bed, the house surgeon, in conversation, suggested the existence of fracture of the base. My reply was, it may be present,

but if we have not an opportunity of examination we are not warranted in placing the case on record as one of this injury.

This, with the other patient, passed to the care of my colleague on his return to town. Frequently, when in the ward, I spoke to the man; his mind was quite clear; he many times complained of being deprived of his snuff box. The only circumstance which attracted my attention was, he always lay on his back, and complained of pain in his head if the nurse turned him on his side. Until three days before his death, when he had symptoms of encephalic inflammation, his mind was perfectly clear. Death occurred ten days after admission.

I was not present at the *post-mortem*, but was informed the brain showed evidence of inflammation, and a fracture passed through the right petrous bone, without involving the tympanum.

Now, I consider the absence of all head symptoms fully warranted the opinion I expressed. The small quantity of blood which flowed from the ear was of no value as a diagnostic, and the trifling complaints of the patient might readily be caused by contusion.

I consider these two cases are worthy of being placed on record. First, a sailor, 20 years of age, was admitted on 16th. June, 1859. While intoxicated he had fallen into the hold of his vessel, a height of 12 or 14 feet, alighting on his head, and receiving a fracture on the left side of his forehead from the sharp angle of a brick. The fissured condition of the bone was visible at the bottom of an extensive scalp wound, it stretched down to the supra orbital foramen, and was of a “+” shape. The amount of insensibility was only partial, as he could tell his name and age. His breathing was natural; pulse 60; skin cool; on being let alone he turned off to sleep immediately. There were two small contused wounds on the left side of the face, one beneath the outer, the other beneath the inner canthus; for some hours continuous bleeding poured from these wounds, followed, for 24 hours, by *copious weeping of serum*. There was considerable extravasation of blood behind the left ocular conjunctiva, and the eye-lids were very much ecchymosed. From this I diagnosed that the fracture, which was traced to the supra orbital foramen, extensively involved the roof of the orbit. I also considered the serum was arachnoidian which had passed behind the ball, and made its way out by these wounds. On the 18th, he had well marked symptoms of inflammation of the encephalon; on the 21st, he had paralysis of the right side; he died on the 25th.—nine days from the injury. Insensibility was almost complete after the first day.

I made a *post-mortem* 12½ hours after death. A large collection of pus occupied the cavity of the arachnoid anterior to the left hemisphere; the arachnoid, especially in the neighbourhood of the superior longitudinal sinus, was thickened and opaque; general

vascularity of the pia mater. On removing the brain, two clots, each about the size of a shilling, were found, one on the roof of the left orbit, the other in the middle fossa of the left side; the brain substance was normal in consistence, but highly vascular in all parts, both cortical and medullary. The fracture in the calvaria was more extensive on the inner than the outer table, without depression, extending from below the left frontal eminence to the margin of the orbit at the supra orbital foramen, in length, say one and three-quarters inch; a similar fissure extended across the top of this, at right angles, producing a T shape. In the base the fracture stretched backwards, from the supra orbital foramen through the roof of the orbit, completely breaking away a piece of bone, nearly circular in shape, of the size of a shilling, rather internal to the centre of the orbital roof; this could be readily removed by the forceps; the continuation of the fracture extended from the left towards the right side, through the olivary process and body of the sphenoid bone, into the right side of the basilar portion of the occipital, terminating half-inch anterior to the foramen magnum. None of the other cavities were examined.

The extravasation beneath the conjunctiva enabled me to express the opinion that the fracture extensively involved the roof of the orbit. The weeping of serum also pointed to fracture of the base. I had never witnessed it from this situation, nor do I recollect having seen it recorded—I think it must be infrequent.

The second case was somewhat similar:—On 11th May, last year, a man, 19 years of age, fell from a scaffold 20 feet high, alighting on his head. On admission he had bleeding from the left ear and nose; he had also extravasation of blood beneath the left ocular conjunctiva; he had symptoms of collapse first; then concussion; during the day he several times vomited blood. As the effects of the concussion passed off in the evening and early part of the night, he was not only able to answer questions, but manifested curiosity as to where he was; how the accident occurred, &c., &c. This continued till within an hour of his death, which took place 13½ hours after the accident. On examination, two fractures extended from the left frontal eminence downwards; one in front of the external angular process, the other behind it; the brain was considerably congested, but was not lacerated or injured in any part; a small extravasated spot was on the most prominent portion of the middle lobe of the left side; another over the superior vermiform process of the cerebellum; and a third on the upper surface of the tentorium, near the right perpendicular semi-circular canal; the brain substance was healthy.

There were two fractures in the roof of the orbit—one at its fore, the other at its back part; both were connected with the fissure which stretched down the forehead; two also ran in the middle fossa and termi-

nated at the foramen ovale. Here the bleeding from the ear and nose, with the vomiting of blood, pointed to the existence of fracture of the base; the extravasation behind the conjunctiva, to injury of the orbital roof.

In the former case, the fracture stretched into each of the three fossæ, in this the anterior and middle were involved.

Two other instances of extensive fracture of the base came under my notice. One, an elderly man, was knocked down in the street by a blow from the shaft of a car, he lived five days. On *post-mortem* at least one ounce of blood lay between the dura mater and the skull-cap; there were three clots on the surface of the brain, and there was laceration of the grey matter on that portion of the middle lobe which occupies the middle fossa; the calvaria was most extensively broken, and the anterior and middle fossæ fractured. The other, also an elderly man, had fallen down the cabin stairs of a steam boat, a height of about 12 feet; he lived 24 hours. On *post-mortem* the condition of the brain and membranes was much the same as just described; there was no fracture of the calvaria; in the base the middle fossa was extensively broken, and the lesser wing of the sphenoid chipped off. I do not give the details—as neither of these cases presented features of much interest, but place them on record for future statistical inquirers.

From the accounts of the *post-mortem* examinations, the following were the situations of the fractures:—Of the middle fossa alone there were 11 cases; of the anterior 10; of the posterior 2; of the anterior and middle 4; of the posterior and middle 9; one of these had separation of the coronal suture. There were 5 cases of fracture running into each of the three fossæ; three of these had, in addition, separation of the coronal suture. There were 5 cases in which the precise locality is not described. On analysis of the fatal cases, we may fairly exclude the following, when considering the per-centage of mortality.

First, a case of fracture of middle and posterior fossæ, with fracture of some of the lumbar vertebræ; second, fracture of the anterior fossa, and of the seventh cervical vertebra; third, fracture of middle and posterior fossæ, with fracture of several ribs and other injuries.

In such instances the serious injuries mentioned would of themselves suffice to cause fatal issue.

Again we have unusual, and I may say, necessarily fatal cases, such as a piece of nail-rod penetrating the roof of the orbit, lacerating the brain, and causing copious hemorrhage by rupture of the anterior cerebral artery.

The extremity of a walking-cane passing through the nostril, perforating the ethmoid and sphenoid bones, and impacted in the lower part of the brain.

Brass ferrule of an umbrella perforating the roof of the orbit and impacted in the brain—and a piece of tobacco pipe lodged in the same locality. The last three were only discovered on *post-mortem*. In all, 7 to be deducted from the number of 46 deaths, which would leave 39. Add to these the 5 cases I have now recorded. This would leave the mortality as already stated. I have brought forward some of, to me, the most interesting matters connected with 193 fractures of the calvaria, and 71 fractures of the base of the skull. In all, 264 cases. Many of the matters I have only touched upon would, I know, supply ample material for valuable papers.

SIXTH MEETING
November 30th, 1861.

{Rough notes at back of Council Minute book: President in chair, Gordon, S. Reid, Cuming, Mulholland, Dill, Patterson, Browne, Ferguson, Bryce, Halliday, D. Murray, Aickin, D. Moore, Johnston.}

Compound Comminuted Fracture of the Tibia and Fibula of the Right Leg.

Dr. BROWNE read the following case:—

George Mayers, aged 18 years, a strong healthy young man, was admitted to the General Hospital on the 18th. of October; three hours before, the wheel of a baker's heavy cart had passed over the right leg, about four inches above the ankle. Both bones were broken. At the posterior part of the leg a wound existed about an inch in length; but the bones did not protrude from this, though the bruised tissues did. The limb was put, upon the outside, in a padded splint, and flexed at the knee, and the wound covered by water dressing. Erysipelatous inflammation, with considerable serous infiltration, soon set in, and extended to the knee; and in a week after admission the integuments on the front part, over which the cart-wheel had passed, as well as the posterior wound, had sloughed, exposing the broken ends of the tibia, denuded of periosteum for about three-fourths of an inch. Various contrivances were adopted to keep, or rather to bring, the fractured ends in apposition; but this could not be accomplished. At this time the constitutional disturbance became great, and the suppuration copious; still it was determined to give him a chance of saving the limb. Stimulants and tonics were freely exhibited; and, for some days, considerable improvement took place. However, the sores soon after assumed a very sloughy, in fact phagedenic appearance, the constitutional irritation increased, and there was great infiltration of the entire limb up to the groin, with pain along the course of the saphena and femoral veins, upon pressure. At that time the fractured parts of tibia were exposed for an inch above and below, and a large slough had taken place

in the back part of the limb, behind the seat of fracture. Under these circumstances, though the issue seemed very doubtful, it was evident that amputation must be resorted to, to save life, if possible. The operation was accordingly performed by me, on the 14th. instant, by the double flap of the integuments and circular incision through the soft parts, the bones being cut through three inches below the tubercle of the tibia. Three vessels were tied, and the stump was put up four hours after, with straps of wet lint. Besides the great serous infiltration of the limb, to which reference has been made, the veins were found to be greatly inflamed and blocked up by a clot. He had had, moreover, on two occasions, severe rigors—one a week, and another three days, before the operation.

The opium and quinine, with six ounces of wine, beef tea, &c., which he had been taking, were ordered to be continued. On the 18th. the wound was opened for the first time. The stump did not show the smallest sign of any healing by the first intention; but, otherwise, did not look unhealthy. The infiltration of the limb had greatly subsided; and the pain, on pressure along the veins, was not so great as before. Opiated mercurial ointment was directed to be rubbed along the course of the inflamed veins, and the stimulants, opium, &c., to be continued. On the sixth day after the operation, he had a sharp rigor, which caused some apprehension. On the eighth, pretty free suppuration of the stump had taken place, and there had not been any return of the rigor. On the tenth, the last ligature came way, and the patient seemed improving. On the twelfth day after the operation, however, he had, in the course of nine hours, three severe rigors, followed by profuse sweating. On the thirteenth day, an increased discharge of pus occurred; and there was not any recurrence of the alarming symptoms which caused the dread of pyemia; and he was discharged, four weeks after the operation, with a good stump, and with completely restored health, which had been so much shaken by the results of his unfortunate accident. On the whole the case is interesting, as showing that young persons will survive operations frequently, even when performed under the most unpromising conditions.

The bones of the parts at the seat of fracture were found to have been greatly comminuted, stripped of periosteum, and, in fact, in such a state as to have afforded no chance of repair.

Case of Disease of Hand, requiring Amputation.

Dr. BROWNE showed the morbid parts, and gave the following statement of the case:—

Peter M'Caffrey, aged 54, previously of excellent health, and of temperate habits, was admitted into the hospital—first, in September, 1857, having had the middle finger of his left hand crushed between rollers, so much so that amputation of the part was per-

formed by Dr. Browne, through the first phalanx. In five weeks he was then discharged, with the part quite healed up; and he remained well till the month of August of the present year, when he sustained a kick from a horse on the old cicatrix, which broke up the remaining portion of the first phalanx, and drove the splinters into the palm of the hand. He was admitted into hospital, when Dr. Murney removed the fractured portions of the bone, and took away the former stump at the metacarpo-phalangeal articulation; the parts healed up, and he went out quite well at the end of a month. On the 12th of October he returned with the cicatrix completely opened, and presenting a most unhealthy phagedenic character, with disease of the metacarpal bone. Extensive sloughs, burrowing beneath the palmar fascia, took place, with great enlargement of the wound; in fact the gangrenous state progressed, despite all treatment, till hemorrhage took place which could not be controlled, and rapidly reduced the strength of the patient; this, combined with the excessive pain of the part, was quickly wearing the patient out, so that it seemed amputation was the only resource left, and for which the patient was most solicitous. Dr. Browne, therefore, amputated, a little above the wrist, on the 16th. of November. The stump healed up quickly, and the patient regained his health and strength—the only retarding circumstance to his rapid convalescence having been suppuration of the glands in the axilla.

Compound Comminuted Fracture; Amputation.

Dr. BROWNE exhibited a limb which he had to amputate the preceding week, in consequence of being completely smashed by a railway waggon which had passed over it. The operation was performed through the lower third of femur, by the double flap of integument, and circular incision of muscles—care being taken to make the anterior flap long. The stump promises to be an excellent one.

{Rough notes at back of Council Minute book: Professor Gordon exhibited patient in Hospital recovered from fracture of radius to which he had applied his own splints. Also showed a patient who had sustained fracture of neck of humerus with dislocation. Case with union. No reduction could be made with chloroform.

Dr. Browne using Gordon's splints with greatest benefit.

Professor Gordon: It almost impossible to reduce the dislocation with chloroform even at time of injury.

President remarked on difficulty of reducing.}

Professor GORDON introduced a patient who had sustained an *impacted fracture of the surgical neck of the humerus*, together with fracture of the radius of the same limb.

At the same meeting Professor GORDON showed an arm which he had found necessary to amputate for compound fracture at the elbow joint.

Epulis.

Professor GORDON exhibited a specimen of fibrous epulis, and gave the following details:—

Ann Dyer, admitted into hospital November 9, 1861, aged 18, complexion florid, and her general health very good. About five years ago a small tumour appeared in the gum, opposite the second incisor tooth of the right side. At first this tumour grew very slowly, being at the end of three years scarcely half its present size. On admission into hospital the right side of lower jaw presents a firm oblong tumour, extending from the first incisor to the second molar tooth; it is almost an inch in length, and fully three-fourths of an inch in depth, rising upwards almost to the level of the upper margin of the crown of the canine tooth; it is not painful on pressure; in colour a little whiter than the gum; firm, and slightly elastic; its surface perceptibly irregular from numerous small protuberances.

Around its margin it overlaps closely the neighbouring gum and teeth; the first molar tooth is directed more inwards than that of the opposite; but this seems due rather to crowding of the teeth than to displacement by the tumour, as none of them are in the slightest degree loose. There is increased vascularity beneath the mucous membrane, at its reflection upon the lip, immediately below the tumour.

On attempting to remove the tumour with the scalpel osseous substance was encountered. The scalpel was, therefore, laid aside, and the cutting forceps applied, one blade above and the other below the tumour. The mass was thus easily and perfectly detached; and were I called upon to perform again a similar operation I would use the cutting forceps. The fang of the canine tooth was denuded almost to its point, and an osseous spicula, about one-eighth of an inch in diameter, divided. This spicula projected fully one-fourth of an inch into the tumour.

Although the alveolus between the canine and second incisor tooth seemed sound, yet, from the recognised tendency of such tumours to repullulate, the incisor and canine teeth were extracted, the intervening alveolus removed, and the surface touched, lightly, with *potassa fusa*. On examination of the tumour, after removal, we find it firm, slightly elastic, colour white; its surface perceptibly uneven, with a fibrous section, presenting a groove corresponding to the fang of the canine tooth; and that its point of attachment was much less than would have been supposed from the external examination. When cut into, a small cavity was exposed, filled with sebaceous-like matter, which, when examined by the microscope, is found to consist of plates of cholesterine, oil globules,

granular matter, and a few epithelial scales. The tumour itself seems, on section, to be decidedly fibrous, yet the microscope shows it to belong rather to the fibroid than fibrous tumours. The several cavities containing sebaceous-like matter are, I think, the follicles of the gum distended by a secretion which has undergone degeneration. If we give to this fact its due weight I think it will lead us to infer that the tumour involves, and has its origin, simultaneously in the gum, periosteum, and alveolus.

SEVENTH MEETING

December 7th, 1861.

{Rough notes at back of Council Minute book:

President in chair, Mulholland, Gordon, Browne, Pirrie, Cuming, Professor Ferguson, Arnold, Professor Reid, Johnston, Thompson Senr., D. Moore, M'Gee.

President reported the results of the labours of the Amalgamated Councils with reference to a union of the two Societies. Question was referred on meeting of 26 October.}

Disease of Femur.

Dr. BROWNE exhibited a patient labouring under disease of the left femur, and made the following statements regarding the case:—

The lad, now eight years of age, had, till four months since, excellent health, and is descended from healthy parents, not related by blood. At the time referred to he had a fall upon the hip, but which neither caused fracture nor luxation; indeed he continued to walk for a week after the fall without suffering pain, and without lameness. He then began to keep his bed, and suffered, for several weeks, great pain, with much swelling around the hip, and of the thigh also. The medical practitioner who saw the case in the country, supposed that suppuration was about to take place.

By degrees the pain subsided, and the swelling diminished; but then, for the first time, some five weeks' since, great shortening of the limb was observed to have ensued. When the boy was brought to the hospital, on the 4th. instant, he (Dr. Browne) diagnosed spontaneous luxation at hip joint, with disease of the shaft of the femur. He said he was led to believe, from the history of the case, that acute hip-joint disease had resulted from the fall; that dislocation ensued, after some weeks of destructive inflammation; and that the disease of the shaft of femur had occurred about the same time.

The present condition of the patient, he said, is obvious. The femur is displaced upwards; the head and neck partially absorbed, are resting on, and nearly fixed to the dorsum of the ilium; the shortening amounting to fully three inches; the shaft of femur

and soft parts are greatly enlarged, and the integuments have large veins ramifying extensively through them. The patient's health is good; and there is not the smallest pain on pressure, or on attempting motion of the hip.

Still, even with these negative signs, he could only arrive at the conclusion that cerebriiform disease of the femur is present, and that it would eventually prove fatal. The progress of the morbid growth had not lately been rapid; but the members of the society were well aware that in many of these cases the disease, for some time, seemed almost stationary, when all at once it advanced with great speed; and finally, having burst through the integuments, it soon destroyed the life of the patient, either by the constitutional irritation set up, or, in some instances, by the exhaustive drain of repeated hemorrhages. He concluded by stating he would keep the patient in hospital for some time, would watch the progress of the disease narrowly, and would report the issue to the Society.

Extroversion of Bladder, &c.

Dr. BROWNE introduced a lad of 14 years of age, who had congenital absence of the anterior walls of the lower part of abdomen and bladder; the back part of the bladder projected forward, and exhibited the mucous surface to the extent of about an inch and half square, with the ureters opening at the lower portion. Beneath this the rudiment of a penis appeared, the corpora cavernosa separated above, with a small opening in the sulcus, between the bladder and back of penis, seemingly the mouth of the common seminal ducts.

The testicles were fully developed and enclosed in the scrotum, which approached to the normal condition beneath, but separated above, passing to each ascending ramus of the pubis, the two portions being united by a thin integument and membranous band. The pubes were separated at the symphysis, the interval being filled by strong ligamentous structure. There was no trace of a urethra, except what has been referred to as the openings of the ejaculatory ducts.

Excision of the Tonsils.

Dr. BROWNE introduced a young female, 18 years of age, from whom he had excised greatly enlarged tonsils, and exhibited the hypertrophied parts.

This young girl was of small growth, and not at all developed according to her age. She had suffered, for several years, from repeated attacks of inflammatory sore throat; and latterly the enlargement of the tonsils had become so great as to interfere materially with deglutition, speech, and breathing; and her general health had suffered also. The catamenia had never been properly established, and the mammæ were undeveloped.

Dr. Browne regarded the operation of removal as established in such cases; and his experience of many cases was, that within one year after the excision of the hypertrophied tonsils, in young females, the system became fully developed, and the health quite re-established.

He considered the operation quite safe, provided the surgeon took care not to cut too deep, or outwards; but having drawn the tonsils towards the mesial line, he carried the knife—probe-pointed—with its edge directed forwards, and its flat pressing against the arches of palate, completely through the enlarged mass. Very little hemorrhage had occurred in his practice, and he had never witnessed any unpleasant results.

With regard to the notion entertained by some authors that removal of the tonsils would interfere with the sexual reproductive powers, he said, in the first place, the tonsils never were, and *could not* be excised; it was only the *morbid growth* or *hypertrophied portion* that was removed; and in the second place, he contended that the removal of these morbid growths, instead of interfering with sexual development, actually had the very opposite effect. He concluded by saying that he strongly recommended the operation in all suitable cases—such, in fact, as the one he had introduced to the notice of the society.

EIGHTH MEETING

December 14th, 1861

{Rough notes at back of Council Minute book:

President in chair, Patterson, Mulholland, Browne, D. Moore, Professors Gordon & Reid, Smyth, Cuming, M'Gee, Dill, Johnston, Aickin.

Dr. Gordon extra-capsular impacted fracture, with fracture of radius of same side, question of impaction.

Dr. Gordon compound fracture of elbow joint, amputation, boy in flax mill, carried round drum, different fractures, nerve in pulp.}

NINTH MEETING

December 21st, 1861

{Council Minute book: Dr. Murney, President, in the chair, Drs. Drennan, Patterson, Moore, Ferguson,

[Th?] Reid, Gordon, Bryce, Smith, D. Moore, Dr. Dill, Dr. Johnston, McMechan, Murney.}

Dr. James CUMING read a case of:

*Case of Tetanic Spasm, chiefly affecting the
Extremities.*

On the evening of the 7th. December, I was asked by a benevolent gentleman to see a youth, of between 16 and 17 years of age, who, he said, was dying. On reaching the house, I found the patient—a thin, nervous-looking lad—suffering from very violent pain in the region of the heart and in the limbs. On applying my hand over the precordial region, I felt the heart acting with a violent heaving impulse, shaking the patient with every pulsation, indeed I do not remember having ever felt a more forcible impulse. There was, however, no irregularity, and the pulse did not give any indication of the disturbance at the centre of the circulation, being 84, full, and not remarkably strong. The breathing was hurried. On examining the extremities, I found that the muscles of the forearm were rigid, the wrists slightly flexed, and the thumb drawn into the palm of the hand. The fingers, without being clenched, were so strongly flexed, that a moderate force was not sufficient to open them. The feet were turned inwards and the soles arched. There was no swelling of the joints, nor any tenderness on pressure.

The patient told me that paroxysms occurred about every 10 minutes, and I remained in the house so as to have an opportunity of seeing one. When it occurred, the trunk and limbs became quite rigid and extended, the abdominal muscles were strongly contracted, and the patient screamed loudly.

Observing that the affection presented a distinctly tetanic character, I looked carefully for the affection of the facial muscles, which is so generally present in that disease, but I could detect no trace of it. The countenance was certainly for a moment convulsed with pain, but there was no corrugation of the brow, no risus sardonicus.

I inquired minutely and carefully as to the existence of any difficulty in mastication or deglutition, or of any painful spasm of the jaw, but the patient assured me that he had not suffered anything of the kind, and his relatives were confident that there had been no change whatever in his features or expression. He stated, however, that his tongue had been stiff, and the tip turned up, and that there had been some pains and rigidity in the sides of the neck.

The history of the case was as follows:—He was apprentice to a carpenter, and about a fortnight before, while working out of doors, had been one day exposed to much cold and rain. The day after, he had taken the cramps through his body and limbs. For eight days he had suffered from them, at first about every hour, but subsequently much less frequently,

and three days before my visit, feeling much better, he had returned to his work. But the spasms recurred so violently, that he was obliged to return home, and from that day had become progressively worse. During the entire time, the pain about the ensiform cartilage was the most severe symptom under which he laboured; and his father, with whom he slept, said that he had been kept awake by the beating of his son's heart. The bowels had been pretty regular, and he had been besides two or three times smartly purged with salts and senna; no worms had been passed, and he had always had some appetite.

I ordered small doses of laudanum and tinct. hyoscyami, to be given during the night. In the morning I was agreeably surprised to find that he had slept a good deal, and that the spasms were much less frequent. During the intervals the heart's action was tranquil and quiet, and, even during a paroxysm, the impulse had a much less violent character than on the preceding night. There was no sign of organic disease. From that period the spasms diminished in frequency and in severity, the excited condition of the heart only occurring when the spasmodic attacks supervened, and soon subsiding after their cessation; and on the 13th I allowed him to rise, as no paroxysm had occurred for 24 hours.

The chief points of interest in this case are, I think, the absence of any affection of the muscles of mastication and deglutition, and the symmetrical affection of all the muscles supplied by the spinal nerves, and of that one of the so-called cerebral nerves, which presents, perhaps, the closest analogy to a spinal nerve, the hypoglossal. It is also a question of some interest to remark how closely the symptoms resembled those of a case of poisoning by strychnia, especially when we consider that in all probability the exciting cause of the disease must be looked for in the repression of some excretory matter giving rise to an impure condition of the blood.

{Council minute book: Dr. Reid did not look on case as one of idiopathic tetanus as trismus was wanting, rather as hysterical affection.

Dr. Gordon as neuralgic affection.

Dr. Murney did not consider trismus as necessary to be present, but thought combination of opium and hyoscyamine useful.

Dr. Reid considered it was the rapid disappearance of the disease that negated the idea of tetanus, and did not consider the combination of substances as so opposite in their action as opium and hyoscyamine.

Dr. Ferguson thought that tetanus was slow in progress, said symptoms more marked, that excessive action on heart arose from nervous irritation.

Dr. Murney for Dr. Browne brought forward a case of excision of knee joint.

Dr. Moore looked on case at first as the most favorable to excision.

Belfast Clinical and Pathological Society
Ninth Session: 1861-1862
President Henry Murney

Dr. Gordon do. and felt disinclined to perform the operation in any case.

Dr. Murney looks on amputation as more favorable to persons in [?] close of life.}

TENTH MEETING
January 4th, 1862

{Rough minute book: Dr. Murney President in the chair. Professors Gordon, Ferguson, Drs. Cuming, Patterson, Brian Smith, Browne.}

Popliteal Aneurism.

Professor GORDON introduced a patient who had been successfully treated for popliteal aneurism by compression. There only remained a small tumour in the ham of the size of a pigeon's egg.

Fracture of Femur; Amputation.

Professor GORDON also exhibited the amputated limb, after mill injury, which had caused separation of the lower epiphysis of the femur, and extensive separation of the periosteum.

{Rough minute book: The President remarked that in young subjects generally the periosteum was more easily denuded.

He then exhibited a portion of frontal bone removed from a boy who had sustained an injury of the head, and read a history of the case.

Dr. Browne then described a case of injury of head and neck.

The President described the post-mortem made of the brain.

Profession Ferguson remarked that he had never seen a case of such extensive effusion not followed by sudden death. He thought it remarkable there was no evidence of an extension of the hæmorrhage at a period shortly anterior to death.}

Bright's Disease of the Kidney; Fever.

Professor FERGUSON brought before the society some particulars of a case which, at first, presented the aspect of simple fever. The case, however, did not follow the usual course of the disease. There was constant cough, great epigastric tenderness, and subsequently bloody stools. About 36 hours before death the patient became rapidly worse, and sank without any apparently sufficient cause. At the *post-mortem* examination, all the mucous membranes were found congested, and in both kidneys the usual appearances of *morbus Brightii* were presented. The congestion of the bronchial mucous membrane accounted for the incessant cough. No history which could elucidate the case could be obtained.

{Rough minute book: Dr. D. Moore remarked that it was unusual to find the kidneys both so equally advanced in morbid ...}

ELEVENTH MEETING
January 11th, 1862

{Rough minute book: The President in the chair, Drs. Patterson, Ferguson, Cuming, S. Reid, B. Smith, Murray, Mulholland, Browne, MacCormac, J. Moore, D. Moore.}

Epithelial Cancer.

Dr. BROWNE exhibited two specimens of epithelial cancer which he had removed from the scrotum. He considered them excellent examples of the disease.

Rectal Tumour.

Dr. BROWNE showed a remarkable tumour, removed from the rectum of a boy. It had been attached by a long fibrous pedicle which gave way under slight traction. Its appearance and size was that of a small strawberry. On section, and examination under the microscope, it indicated a striking glandular structure, containing numerous secreting cells, similar to the follicles of Liberkuhn of the large intestine, and lined with columnar epithelium of a very perfect kind.

Compound Fracture of Ulna; Secondary Amputation.

Dr. BROWNE exhibited a forearm which it had been necessary to amputate after severe mill injury. There was extensive laceration of the soft parts, and fracture with denudation of the ulna. In the first instance, after consultation, it was deemed advisable to attempt to save the limb, while it was requisite to remove the lower half of the ulna, the wrist joint being necessarily laid open. The case did not progress favourably, and secondary amputation was had recourse to with a good result. Dr. Browne considered that even had the limb been saved, its usefulness would have been seriously impaired owing to the loss of so large a portion of the ulna, and the destruction of the soft parts.

{Rough minute book: Dr. Moore considered it would have been more advisable to amputate in the first instance as when so large a portion of bone was lost, a useful limb would not remain.

The President observed that if the wrist joint had been intact the chances of recovery would have been greater, and then it would have been necessary to speculate what amount of use would have remained to the limb.}

Caries of the Metacarpal Bones; Amputation.

Dr. BROWNE exhibited the fourth and fifth fingers, with portions of the corresponding metacarpal bones

which he had removed from a patient admitted to hospital for what was at first a simple phlegmon. This had been treated in the usual way, and the patient left the hospital almost well. In a few days he returned, unhealthy action having set in; and, on examination, the metacarpal bone of the third finger was found distinctly carious. It was surmised, but could not be clearly ascertained, that the fifth metacarpal was also diseased. Under the circumstances it was decided to amputate the diseased portions of the hand, and to be guided in the steps of the operation by the condition in which the fifth metacarpal might be found.

Council Council Meeting January 15, 1861.
Present, Dr. Murney President, Drs. Browne & Mac Cormac.

That a special meeting of the Society be summoned for Saturday to elect a Secretary in place of Dr. W. Aickin resigned.

Dr. Browne undertook to exhibit a case of recurring malignant disease after extirpation.

TWELFTH MEETING
January 18th, 1862

{Rough minute book: With reference to a letter received from Dr. Jacob Junior it was moved by Dr. Browne and seconded by Dr. Patterson and resolved "That Dr. Jacob be informed that arrangements have been made for the publication of the transactions of the present year, but that he be thanked for his attention and informed that his proposal will be considered at the ~~close~~ commencement of the present session."}

Melanotic Tumour of Orbit.

Dr. BROWNE introduced a woman of 30 years of age, labouring under melanotic tumour of the orbit. In this case excision of the eye-ball, for melanosis, had been performed by him two and a half years ago. At that time the tissues external to the eye-ball were not affected. For 18 months after, the patient enjoyed good health, when a small tumour began to be observable at the inner canthus, growing slowly at first, but latterly with rapidity, extending down the cheek, and probably into the nasal cavity, as there is at present a sanious discharge from the nose. It is now of a year's duration, in length two and a half inches from the margin of the orbit to its extremity, and rotund in shape. Sensations of acute pain are occasionally experienced in the part, followed by a discharge of blood from the nares which relieves the pain for the time. None of her relatives suffer from any form of cancer, nor can any history of it be traced in her family. Dr. Browne stated that, under all circumstances, melanotic and cerebriiform tumours of the eye-ball are most liable to recur. In six cases of this form of

disease in which he had extirpated the eye-ball, there was only one in which the affection did not return. Operative interference with this case would be useless now, the disease having implicated the wall of the antrum, and extended into the nasal cavity.

{Rough minute book: The President had seen melanosis only in those of dark aspect, with much pigment.

No doubt minute structure of melanosis is identical with other forms of carcinoma with addition of pigment. Hard forms of melanosis proceed with same rapidity as schirrhous, soft forms of melanosis with same speed as cerebriiform.

Thought it soft form of cancer now. Interesting to observe loss of sensation over parts supplied by infra-orbital nerve.}

Congenital Cataract.

Dr. BROWNE introduced a case of double congenital cataract in a boy of thirteen years of age.

Both eyes had undergone the "needle operation," and were progressing satisfactorily. Dr. Browne remarked, with respect to the period of life in which the operation should in such cases be performed, Mr. Saunders considered that it should be done early; whilst others held that there was a risk of too active absorption after needle operations in infancy. Dr. Browne agreed with Mr. Saunders, as when an early operation was had recourse to, the children were enabled to be educated at a proper age, and the eyes had not acquired the habit of rolling about in search of light, which is extremely difficult to counteract when the muscles have once acquired it.

Since the operation the boy stated that all surfaces, whether prominent or not, appeared flat to him, and he evidently imagined all objects to be much nearer him than they really were, arising, no doubt, from the want of a proper idea of perspective.

*Cataract.*¹

Dr. BROWNE also introduced a case of double cataract in a girl of fourteen years of age, in whom one eye had been operated on. The needle operation had been performed on the right eye on the 29th. October. Smart inflammation ensued, persistent, requiring the repeated application of leeches. A small bit of the capsule of the lens still remained unabsorbed. Dr. Browne remarked that, when the lens is in a semi-fluid condition, there is much risk of inflammation if the needle be too freely used. In this case, although its use had been slight, yet smart inflammation had set in. This girl did not suffer from any inaccurate appreciation of distances, like the boy previously introduced, as her sight had been pretty good until two years ago.

¹ [See page 889.]

{Rough minute book: President considered there could be no objection to operation in childhood—and would expect from activity of capillary circulation that a slighter touch of needle would suffice.

Dr. Browne thought children less susceptible of inflammation than adults. }

THIRTEENTH MEETING¹

January 25th, 1862

Strangulated Incarcerated Femoral Hernia.

Dr. BROWNE read notes of a case of strangulated incarcerated hernia in a female of 40 years of age, in whom death had occurred from peritonitis, two days after the operation for the relief of the constriction.

The patient had laboured under incarcerated femoral hernia for the past two years, for which she had never worn a truss.

On the 14th. of the present month she first complained of pain in the site of the tumour. On the 15th. vomiting set in, and on the 16th. she was admitted to hospital.

On admission she experienced general and diffuse pain over the whole surface of the abdomen—most marked in the vicinity of the tumour. Her face was pale, shrunken and anxious. Pulse 130, and scarcely perceptible.

On consultation with Dr. Murney it was considered advisable to operate, although sub-acute peritonitis had evidently set in.

Chloroform having been administered, the tumour, 3½ inches in length by 2½ in breadth, and in depth two inches, was cut down upon, the sac opened, and found full of apparently healthy omentum, on raising which, a knuckle of the ilium, three inches in length, of a very dark chocolate colour, but still retaining its glossy appearance, was found.

The stricture having been divided, the intestine was gently drawn downwards, when the part above the site of constriction being found healthy in appearance, the gut was carefully returned—due care being taken that no part of it was constricted by omentum.

After the operation the vomiting ceased, but the pain and tenderness of the abdomen still continued, and the pulse, which had risen under the influence of the chloroform administered, became almost as rapid and feeble as before. It was evident that the operation had afforded little or no relief to the shock inflicted by the strangulation of the bowel.

Next day, on finding considerable fulness of the great intestine, an enema of oil and turpentine was exhibited without effect.

The patient gradually sank, and died on 18th, 51 hours after the operation.

On *post-mortem* examination, the great omentum was found much congested in its upper and middle portions; its lower border being inflamed, in a soft and ragged condition, and coffee coloured in appearance. It was adherent by lymph to the inner aspect of the opening through which the protrusion had occurred.

The small intestine, generally, was congested, and for the distance of several feet, on either side of the constricted portion, presented marks of inflammation, with spots of lymph exudation, of the size of a shilling, or larger, scattered over its surface. The part which had been engaged in the protrusion was highly inflamed, of a dark chocolate colour (which scarcely seemed, however, so dark as at the time of the operation), its surface being studded with lymph exudation.

Parietal peritonitis existed over the lower three-fourths of the abdominal cavity, which contained a pint and a-half of effused serous fluid. The ascending and transverse colon were full of feces.

Dr. Browne remarked, that although the presence of peritoneal inflammation, in cases of strangulated hernia, renders the prognosis very unfavourable, still it should not deter the operator, as the inflammation frequently begins to subside on the relief of the stricture. He had lately operated for the relief of a strangulated femoral hernia, of four days, duration, where subacute peritonitis also existed, and where, on opening the sac, upwards of 40 ounces of highly coagulable serum flowed away; yet, on the relief of the constriction, the unfavourable symptoms gradually abated, and the patient did well.¹

{Rough minute book: President showed that omentum united to wound would prevent recurrence of prolapse. Hernia largest one he had ever seen.

Dr. Ferguson, operation successful as by P.M., asked Dr. Browne, cause of death no doubt peritonitis, whether peritonitis existed formerly to operation is not [clear].

Dr. Browne stated that peritonitis existed before operation and continued unrelieved.

Dr. President that signs of inflammation had been unfavourable. At operation appearance of gut looked better.

Dr. Ferguson asked how far peritoneal inflammation could go.

Dr. Murney stated that no estimate could be formed from length of time of constipation, amount of pain, as one person had more promise of recovery than another.

Dr. Brown would operate in all cases unless in articulo mortis. Gut sphacelated, patient may have

¹ [Text is recorded in the Transactions as belonging to the twelfth meeting but examination of the rough minute book suggests the text is from the thirteenth.]

¹ [See *Dublin Quarterly Journal of Medical Science*, 1852, v13, p218, for a similar (if not identical) case described by Dr. Browne.]

artificial anus, so that no amount of severity of symptoms should preclude operation. Two cases in Hospital since Dr. Browne was attached that recovered against all hope.

Ferguson: Dupuytren came 5 or 6 mornings to bedside of patient in hernia who refused operation. On last morning, gave consent. Dupuytren said “I can do nothing for you, you will be dead in 12 hours”—no doubt from peritoneal inflammation.

President asked if there was any evidence linking of pulse—no.

Dr. Browne said that Dupuytren saw that man was in articulo mortis and hence would not operate.

Dr. Johnston: Patient admitted to Richmond, morning, no urgent symptoms. Bath and taxis, no success. In evening another bath, patient got into collapse. Perforation, great hemorrhage had taken place into bowels. Had knife been used, and less taxis, good effect.

President asked from what point hemorrhage came—from both above and below strangulation, the whole ileum.

Dr. Browne as to loosening of sac or not? Drs. Luke and Gray advocated non-opening of sac in many cases. The patient would be far worse than at first if sac not opened. In present case you could not tell where obstruction existed or whether knuckle of intestine was strangulated by omentum or not. Stricture often exists in neck of sac itself.

President always opened sac and that benefit of opening more than counterbalanced additional danger. Little added to risk by it. If strangulation tight and existed for considerable time the gut may be gangrenous, and if returned sac unopened, effusion into cavity to abdomen. If opened a false anus may be formed.

In a recent hernia, small and only gut, would not feel inclined open sac.

Dr. Ferguson—acute rheumatism, in 12 hours had 6 gr opium. Next 24 hours had 18 gr as extract. No narcotism. All local rheumatic affections removed save pericarditis one. So much opium in 24 hours, with no narcotism—it purges bowels, produces thirst and slight feverishness. Think opium most useful agent known in pericarditis.}

{Rough minute book:¹
FOURTEENTH MEETING
February 1st, 1862

Present, President in the chair, Drs. Ferguson, Seaton Reid, Browne, Patterson, Johnston, Murray.}

¹ [From here on the records of the meetings are found only in the Rough Minute Book. Most cases were not recorded in detail but the discussions were. The scribbled notes are not so easy to read and contain a number of gaps and guesses.]

{Rough minute book:
FIFTEENTH MEETING
February 8th, 1862

President in chair, Drs. J. C. Ferguson, Patterson, Cuming, Bryce Smith, Halliday, W. MacCormac, Mulholland, Dill.

After minutes read. President stated: 35 town and 7 county members had answered in the affirmative—2 town [?] since. 37 + 7. forms sent out no replies yet.

Only one negative answer.¹

18th man admitted with haggard emaciated aspect, no well defined complaint but referring gut malaise and abdominal pain. 5 weeks ago [amount?] diarrhoea but never altogether unequal to his work. For last 2 or 3 days bowels confined.

On 19th occasional diarrhoea followed by occasional costiveness. Ordered ʒij ol R. and ʒi ol turpentine [and] ʒi [?].

20th Next day better. No local pain or uneasiness. Asked for and ate a better diet. Only sign was foul tongue with dark streak down centre. Had grX pill [Rhubarb?] co, night and morning. Open diet.

21st Pills had no effect. Ordered ʒi oil with success and marked relief.

On night 22nd began to complain of pain in abdomen. On 23rd countenance altered and more miserable. When suspicion of abdominal affection were confirmed—peritonitis—turpentine stupe, gr iij grey pulv and gr iij Dover, every _ for 23 and 24. On 25th aspect altered for worse of extreme anxiety, but it was not the pinched expression of extreme peritonitis. Still very considerable pain and uneasiness. 24th abdominal parietes retracted, but tenderness comparatively slight unless over region of bladder. Also dysuria.

25 Much pain in abdomen, refused food. That night restless and sleepless. At 8 a.m. on 26 he suddenly became weak and delirious, refused no special pt. as seat of affliction. At 11 a.m. died quietly.

That peritonitis arose from extension from mucous surface of inflammation and ulceration.

P.M.: Mesenteric gland in direct connection with the ulcer. All glands of the mesentery that were enlarged were in direct connection with ulcer, and were effect not cause as some maintained of ulcer.

1 When did inflammation set in

2 Of what was it effect

3 When did perforation occur

Man had subacute inflammation for some time previously. How long lying dormant cannot tell but when gut arises from extension of institution from mucous surface prior to perforation. That perforation was of late date of sometime during Saturday night.

¹ [It is very likely that these were the results of a ballot on a possible merger with the Belfast Medical Society.]

A case similar occurred in Dr. Ferguson's house and died in 24 hours after with all signs of perforation. 4 or 5 months ago had severe colic, burning piles and loss of appetite. Purgation full by anodyne. For several visits same treatment. Man recovered so far as to attend to his business. 3 weeks after called at his house. Tongue dry, brown. Loss appetite, nausea and appearance of man in typhoid fever. There was much difficulty of diagnosis—1st typhoid fever, 2nd malignant disease. Had blue pill and opium. Turpentine stupes. From that time until admission time had not seen him.

Existence of only one ulcer would militate against typhoid fever. That perforation may have existed at time his admission to hospital. Thinks that peritoneal inflammation may have extended from mucous coat, but thinks that when much suffering from ulceration has occurred, symptoms of effusion are not so urgent.

Dr. Ferguson: Amount of peritonitis not necessary to find cause of in perforation—inflammation set up often to [?] Effusion. The formidable symptoms set in suddenly on Saturday night.

President: That chronic peritonitis has existed for some time, and that perforation occurs when formidable symptoms set in.

Dr. Ferguson: Doubts if such care were given by purgatives but happened, had peritoneal inflammation existed then. When peritonitis set in purgatives lost their effect.

Dr. Pirrie mentioned case ...

Ferguson: That if signs of inflammation and increasing and final death. He thought ...

Halliday: ...

Dr. Cuming: That there was something more than mere ulceration of intestine.

[?] for idiopathic ulcer of intestines. In Crimean cases there were no ulcers.

Are we entitled to date the perforation from ... life has been prolonged for upwards of some days after a perforation so he would not date perforation, but probably on Saturday morning.}

{Rough minute book:
SIXTEENTH MEETING
February 15th, 1862

Present, President chair, Drs. Moore, Ferguson, Dill, McMechan, W. McCormac, Bryce Smith, Pirrie, Gordon, William Magee, Cumings, Browne, D. Moore, Bryce, Halliday, Mulholland, Johnston.

Dr. Ferguson read notes of a case of acute rheumatism with cardiac, pleural and peritoneal complications.

Dr. Pirrie: Dr. Ferguson ascribed good effects to opium. 1st alkaline treatment adopted and after carb potass. materies morbi and that of acid nature and Dr. Pirrie ascribed gradual effects of alkalis to counteract

of this—opium as adjuvant, calomel, that when peri or endo cardial affections, the joint symptoms may [mean?] do disorganisation and calomel necessary. If no heart affection no calomel necessary.

Dr. Cuming: As to diarrhoea, is opium cause of it. Opium in poisoning has sometimes shown signs of action as irritant. Might not diarrhoea have occurred without opium, and as an elimination of poison, and would seem to act as natural indicator of disease.

Magee: In active disease large amounts of opium may be [laxative?]. Agreed with Dr. Pirrie, same as to materies morbi of acid character and benefit of alkalis, if so, how. Lemon juice useful.

Pirrie: Lemon juice other acid has small affinity for alkali and easily decomposed and [Potass?] produced good effect.

Browne: Case of 12 gr opium for 3 days.

Prostration, diarrhoea, vomiting in opium [?] it acts as a purgative

Dr. Pirrie: when serous tissues are affected would combine Cal[omel?] with opium.

S. Reid: Citric acid acts as sedative on heart and large [dose] will lower heart's action from 100 to 70 or 60 in 24 or 48 hours. Acts as antiphlogistic.

Dr. Ferguson reply: As to Dr. Murney's relapses, 70 exposed, only alkaline [?] [?] 2 oz. fluid magnesia until rheumatism had entirely disappeared. 20 no benefit from alkalis. When extension of inflammatory rheumatism from joints in patient to pericardium, pleura and peritoneum, he yielded in his views [generally?] entertained but he wished he had not and had seen pericardial effusions yield to opiate treatments solely. As to diarrhoea, Dr. Ferguson had never used opium in large doses for rheumatism but it was followed by gastro intestinal irritation, and as to diarrhoea (as Dr. Cuming stated which might have proved useful) forming as [?] he had given purges freely.

Pirrie: As to peritonitis, Dr. Pirrie had never seen it in acute rheumatism before. Would ask Society if they had.

President: Do. Had seen case and agreed with Dr. Pirrie as to only case.

Ferguson had never seen *meningeal* inflammation and instanced case where all membranes save meninges.

Dr. Gordon exhibited a case where 3 inches of bone end of fibula for scrofulous caries, epiphysis was found diseased but with finger was scooped out, and this is part of case.

Dr. Gordon read notes of a case of symptomatic pelvic abscess. Disease began 1st in hip, through acetabulum, and up to abdomen.

Dr. Magee: Gordon had said that he had no proper examination. Why did he not give chloroform.

Dr. Pirrie could not adhere to Dr. Gordon's explanation. Agreed with Dr. Read as to came about in form ...

Murney: united tendons of psoas and iliac pass in front of joint which often arrangement might no inflammation be carried up tendon into general body of psoas and iliac muscles. That so much existed as that a perfect examination could not be had for long time.

Johnston: Walked a mile with assistance to dispensary. No pain in knee or hip, but tender over iliac fossa. Had suspicion of peritonitis. The leg not then flexed as it after became. Considered that no opening through acetabulum but that it was made by finger.

Dr. Ferguson: Thought disease began in hip as Dr. Gordon stated. Unusual for dislocation to occur in 3 weeks.

Dr. Browne same as Dr. Gordon, ...

Johnston 7 weeks elapsed since the diagnosis of pelvic abscess.

P.O. Treasurer 3/6 received for Transactions.}

{Rough minute book:
SEVENTEENTH MEETING
February 22nd, 1862

Present, President chair, Drs. Drennan, Browne, Ferguson, Patterson, McMechan, W. MacCormac, Cuming, Halliday, Moore, Dundee, Dill, Murray, Mulholland, T. Thompson, Bryce Smith.

Minutes read.

Dr. Dundee's case ...

Dr. McMechan read notes of the latter part of the case.

Dr. Halliday: 6 hours after accident no thickness of speech. No hemorrhage from nose, mouth or ear. No swelling of temporal fossa. No brain matter on end of stick. It might have passed into temporal fossa.

Dr. Browne, in temporal fossa although review refines as crowbar, breach of [?] and [?] still temporal fossa. Thinks man will lose the sight of 2nd eye, that irritative inflammation will act in 2nd eye. In temporal fossa not from direction [but] damage to nerves and no paralysis, inflammation in temporal fossa.

President agreed with Dr. Dundee that injury to temporal fossa would not induce a pulse of 58 or lower for weeks. A nail 4 inches long was drawn from supra-orbital ridge with brain matter on end. No constitutional symptoms.

Ferguson: No spiculæ of bone came away?—none. That if it entered brain, spiculæ of bone would be carried in and would induce serious consequences— injury to nerves at that part of brain—and yet no paralysis appeared.

President: That it penetrated into middle fossa of base of brain, into [?] of grey matter, what would become of spiculæ of bone if [?] went into temporal fossa.

Johnston: Asked as to medico-legal matter.

Browne: Weight of medical would go to [?] that when ...

Dr. Ferguson: A physical impossibility for sharp lathe in ...

Dr. Dill: Not temporal fossa. More uneasiness and that a person will not suffer much from excision.}

[There is sketched a rectangle in the book. May be a doodle or may be a representation of the foreign object which penetrated the brain.]

{Rough minute book:
EIGHTEENTH MEETING
March 1st, 1862

President chair, Drs. Thomas Reade, Patterson, Dundee, Dill, Drennan, Cuming, W. MacCormac, Johnston, Browne, Moore, Gordon.

Minutes read.

President read report from Council meeting of Medical and Pathological Societies.

Dr. Drennan read notes of a case of aneurism of thoracic aorta, and exhibited morbid pathology.

Dr. Murney explained parts—at first true and after false aneurism—Bellingham's mixed aneurism.

Dr. Drennan asked Society cause of diastolic bruit—regurgitation of blood from aneurism into aorta. The pulsation of carotids interesting. Nodules on aortic valve. Could some be called an imperfection in this case, though carotid pulsation varies with aortic regurgitation through valve.

And mobility of radial with small and feeble imperfect pulse. The pulse was distinct from the half-filled pulse of aortic regurgitation.

State of pupils—had an opiate.

Emphysema of lungs, had no cough and fits dyspnoea were attributed to aneurism.

Effusion into right pleural cavity must have occurred immediately before death as day before chest examined and clear.

Dr. Moore's case of pancreas ...

Dr. Gordon had seen [?] of gallbladder ... and obstruction of common duct by gall-stone, diseased pancreas, &c.}

{Rough minute book:
NINETEENTH MEETING
March 8th, 1862

President chair, Drs. Gordon, Ferguson, ...

Dr. Gordon: in abducting arm felt a tear, thought it due to ligament giving way. On removing soft parts

found fracture glenoid cavity extending down anterior border.

... fits to a form of accident he thinks connected when [?] such an accident may happen. If circumstances were in force it is well to know such may be [?]

Bones generally were atrophied, shafts of long bones [?]

Dr. Moore: if muscles rigid.

Dr. Pirrie—patient complaining for 15 months, off work for 5. A few weeks before, admission complained of laryngeal stridor and laryngeal cough and dyspnoea.

Dr. Smith had considered it aneurism.

A small aneurismal tumor back part of aorta where transverse part ends, lying over oesophagus and touching trachea. [?]. Never difficulty of swallowing or inspiration. Difficult cough from below with expiration.

President as to relative frequency of open into trachea or oesophagus.

Ferguson—on tube fixed and resisting and when soft and yielding and would give every accts so for want of dysphagia Pain

Dr. Gordon—Pain if pressure on intercostal nerves. Simulation of laryngeal affection. Mentioned a case in point.

Dr. Moore—Paroxysms

Dr. Gordon—Anything that determines to increased pressure would give rise to paroxysms. Mental symptoms, change of position etc.

Ferguson—Diagnosis, [?] enlarged and very high, one sign. Benist no necessary altered [?] aneurismal tumor, a tumour of that size and locality might be detected by pulsation lone.

Dr. Johnston—If atheroma ...

Dr. Gordon—Aneurisms due to partial atrophy of middle coat in many cases and no atheroma.

Dr. Moore—Fatty tumour ...

Dr. Moore—Hand ...

Sloughing wound, sufficient for stump, hysterical, no chloroform.

President: as to hysteria, and no chloroform, is it desirable to omit it. Would give chloroform as stimulant same as in collapse, as stimulant to rouse from collapse or hysteria.

Dr. Pirrie: Hysterical woman, chloroform not necessary.

Ferguson: On touching by M. if mesmerism would produce insensibility as this hysteria.

Johnston: Odd that the knife would not rouse from hysteria.

Dr. Johnston—Peritonitis. Whether from pressure or [?] or ulcerated margins.

Dr. Dill—Kidneys of dropsical patient, woman 60, who died of influenza.}

{Rough minute book:
TWENTIETH MEETING
March 15th, 1862

President in the chair, Drs. Drennan, Patterson, Thomas Reade, Gordon, Bryce Smith, S. Reid, Dundee, Dill, W. MacCormac, D. Moore, Cumming, Browne.

President read notes of case of femoral aneurism treated by compression and exhibited patient.

Gordon: Signorini compressor, 3 sloughs of vessel tied, wound would slough. Signorini's compressor more easily applied. Patient's thanks. Until complete stop of all pulsation for some hours at a time. A progress to case occurred.

Dr. Browne: Not necessary in most cases to completely arrest flow, merely minimal current.

Gordon would bandage for a fortnight if the patient muscular before compressor applied.

Dr. Browne exhibited patient ... Said ligature put on high up, none below. Wound of vessel. 6th day, 2^{oz} hemorrhage, thigh enlarging. Wound opened. Pus large in amount 30oz. Bleeding point where anastomotica magna was given off. Ligature applied, [sacs?] to common and both vessel and anastomotica magna. 12 to 18 ounces of pus daily came away or 3 or 4 weeks. Leg was kept completely bandaged. Ligature came away, 13 day 1st ligature came away, 18th day of wound, (2nd do.)

Dr. Dill's case ...

Dr. Drennan: No pain [?] save for 12 hours. Sharp in character. Some days previous admission vomiting oily, bilious matter.

Tumor middle and left hypochondrium. Suspicion of accumulated faeces. Purgatives tumor less. After going off duty, saw her again. [Later?]. Tumor on right side which had not previously existed. No pain except vomiting and diarrhoea ceased. No prominent symptoms at that time. Tumour had a sharp pulsation but not of the expansion characteristic of aneurisms. No bruit. No suspicion of aneurism. Had appearance almost of malignancy. No vomiting of blood. No symptoms of stomach affections.

Dr. Browne sent in a small tumour, liver—no oily matter in stools.

Dr. Cumming: Difficulty of diagnosis, liver not easily diagnosed in this case. Spleen, dulness well marked. For right lobe of liver did not to him present nodular form. So much affected of left side, little of right. Of long standing. Broke down. Jaundice not prominent with all that disease of liver.

Dr. Gordon—Hydatid disease of omentum. Medullary disease of liver ascending as high as 4th rib. Organ generally enlarged. Right hypochondrium the liver no enlargement, left mass irregular, different degree of consistency. Beneath left mass tympanitic sound on percussion, in front of stomach distended with wind, however, not spleen, for stomach would have been displaced to the right by it.

What are circumstances thus determining the rising of liver or sinking as in this case.

Conjunction diarrhoea.}

{Rough minute book:
TWENTY-FIRST MEETING
March 22nd, 1862

President chair, Drs. S. Reid, Dill, Ferguson, Bryce, Smyth, Mulholland, Patterson, Drennan, W. MacCormac, Cuming, D. Moore.

Dr. Reid read notes of cases of [heart disease] and exhibited recent parts. ...

1st no murmur. 2 apex and systolic. 3rd at base and systolic too.

Dr. Ferguson considered valves aortic sound. Would not look upon small action of vessels [?]. Regurgitant. Did not understand *triple* motion of blood waves.

Dr. Reid: Imperfect tricuspid orifice and wave came up *in vein* after systole.

Dr. Drennan: Marked visible pulsation in large vessels of neck and extremities with small pulse. Bruit depends on dilatation of vessel and not on imperfect aortic valve.

Ferguson: *Visible* pulse not except with aortic incompetency. For dilatation will if it comes close enough to valves so separating them so that they admit of regurgitation.

Dr. Drennan did not agree.

Cuming: If rigid unyielding tubes, on physical principles, not visible pulsation. If vessels so dilated as to lose contractility there would not be a visible pulse.

Dr. Ferguson proposed a discussion on pulsation of vessels without aortic regurgitation.

President—13 January, a man 56yr admitted under Dr. [Ph?] in America under treatment. An instrument was passed with force but no urine.

Dr. Browne: All [?] passed same distance. No success to point anterior to bulb urethra. Passed copious pus in urine. No perineal section [?] and no passage. Sound passed and cut upon—unsuccessful as point behind stricture could not be found. Died with stricture unrelieved.

Urinary fever—Syme always opening [?] no orifice to be found. But no opening, structure seems to be ...

Dr. Johnston: Case Richmond of Dr. Adams, failed in same way. The distal opening was not to be found. Dr. Johnston made P.M. and parts just same as in the present case. $\frac{1}{8}$ inch of stricture not cut.

Dr. Ferguson: A chance of life from state of bladder and kidneys had operation been successful.

President: Large amount of pus in urine was from collection of a bladder and inability to pass it. Local in bladder with thickened coats. Symes operation from 2nd case usually not fatal.

Dr. Browne: Operation only chance; agree with Dr. Ferguson.

Johnston: Differed—saw no reason why he should not live for years.

W. MacCormac: Nélaton drew a diagram showing impossibility of passing an instrument through canal, and [why?] instrument would not pass.

President: Size of stream a measure of size stricture, immediately given anterior to bulb. Expulsion of urine is mainly affected as the stricture passed the urine is expelled with violence.

Dr. Brown's case ...

President: One ligature put on, 2 better. Distance of single ligature 2 inches from main vessel objectionable. When ligature placed on distal side of vessels hemorrhage did not come at once.

[?] of sutures difficulty of seeing vessels at all for venous hemorrhage.

W. MacCormac: No hemorrhage at admission. Not desirable to operate unless hemorrhage resumes. Erichsen. [?] [?] [?] [?] in pain. Hemorrhage easily controlled, no interference, good result.

President: Wounds [?] if punctured wound in axis vessel. May heal without trouble. Was vein wounded. [?] circulation does not spout, wells up.

Dr. Moore: Ligature on lower point of vessel.

President: [?] [?] blood, and pressure brought would check arterial bleeding too as well as venous.}

{Rough minute book:
TWENTY-SECOND MEETING
March 29th, 1862

President chair, Drs. Drennan, Patterson, Gordon, Thompson, Ferguson, S. Reid, Stewart, Dundee, W. MacCormac, Dill, H. Cooke, D. Moore, Johnston.

Minutes read and signed.

Dr. Dill—"Bright's". Notes of case read and kidneys exhibited. Specimens of Bright's disease.

Dr. Reid: Any peculiarity of inspiration, not guttural from back of throat.

Drennan: Heart complications common in Bright's disease. Any enlargement of heart would tend to cause effusions and dropsy, and effusion [neck] into

head. Coma may depend on that effusion found heart as well as from uræmia.

Johnston: Cases where only œdema a slight present, and yet head affections from *uræmia* present. One case 48 [?] died.

Ferguson: Case of John Porter, aggravated Bright's disease, comatose for several days and nights and yet recovered, and was alive for months or a year. Shortly before same case end fatally albumin will disappear. Specific gravity never seen to vary. Of *modus operandi* of poison much yet to learn.

President: Also [?] of albuminuria when well ascertained and have been present for a tumor, and disappearing for years say. Desquamative nephritis has spoiled parts of kidney which no longer separate urine from blood, other parts carry on function. When albumin appears it is owing to fresh attack of same part.

Dr. Dill: Interesting that so much urine was passed as there was, with such atrophy as kidney, and no swelling of body of limbs.

Dr. Dill: Reilly—liver ...

Jaundice depending on inflammatory closure of hepatic duct.

Dr. Drennan: Woman 3 months ill. No marked symptoms save a change of color, some constipation. 1 month before admission some swelling and tenderness in hypochondrium. Bowels costive on admission and white. Urine very dark and showed the lime yellow.

Cupped and leeches, calomel, mist alba. A few days later stools became remarkably dark. Seemed better. Afterwards blue pill and [tara?] and [?], gums touched. Stools alternated white and dark occasionally. At end of month 28th day, came in on 12th January, had stinging pains in liver. Itchiness of skin did not occur till *after* jaundice. Graves mentions cases in which itching preceded jaundice.

Dr. Ferguson: Perfect obstruction probably did not occur till after dark stools ceased. Was it inflammation of lining membrane of ducts.

Gordon: Affords a case of jaundice from contraction of Glisson's capsule or before from pancreas. Can we form a differential diagnosis—an enlargement and softening of liver or biliary system but here contraction.

Dr. Reid ...

Dr. Drennan: Yellow appearance of objects ...

Dr. Ferguson: Has man sees yellow tinges of objects.

Dr. [Reid?] known patients say but rarely that white objects looked yellow.

Dr. Drennan said Dr. Graves had noticed it.

Dr. Dill: Gall bladder empty. Occasional tinge of stools might be due to small quantity passing obstruction to intestine until it was emptied.}

Council Council Meeting April 2nd

Present, Drs. Moore & W. Mac Cormac.

The Saturday business was arranged.

{Rough minute book:

TWENTY-THIRD MEETING

April 5th, 1862

Dr. Patterson chair, Drs. Reid, McMechan, W. Mac-Cormac, Dill, Moore & Moore.

Dr. Moore—Selston—Strumous affection of ankle joint, tibia and fibula. Excitable pulse, hectic feverish, [?] and much disabled. Good foot [?]. Circulation settled. No movements of joint [?] which would aggravate. Erosion of cartilage and bare bone. Movement would irritate and aggravate malady.

Paralysis of side of face. [?] cicatrix of neck. 2 long flaps and circular muscles. Wound healed almost by 1st. intention. 2 arteries only [?] out of 3. A similar case but much more hopeful, good air. Joint much in rotten condition. Boy died. Woman not [?] hectic and induration. A similar case in Antrim. [?] not favourable.

Dr. Moore—Amputation after surgery—dislocation.

Foot ankle swelled, pulse 160. 2 long flaps [?] head of tibia. Anterior flap long and come behind line of bone. Circular muscles. Healed almost by 1st. intention. Fibula end higher up [?] 1ⁿ. Did not level front of bone as [Jennet?] recommended if plenty of flap not required. Patient doing well, will [mobilise soon?].

Dr. Moore—Fatty tumor. Said carrying weight on back gave rise to it. Some uneasiness and annoyance as it had rapidly increased latterly. Report—firmly attached at lower and upper points, cellular tissue. Venous hæmorrhages in most fatty tumors. At first [point?] one artery and *pain* on cutting. 3 or 4 ozs. blood lost. Wound after filled with blood as large as inguinal tumor, sponged and healing by granulation. (Other case 7½ lbs. weight and only two arteries. Wound healed almost 1st intention.

Dr. Moore—Cyst from eyelid, male. Cyst thin, in outer and upper part of upper eyelid. Tumor removed perfect. Skin healed 1st intention except at lower part of incision. Sac granulated, in five days, discharged.

Cyst, lower eyelid. Thin quantity of fluid. If fluid discharged it would be filled again, and cicatrix under it hard to remove from skin. Subsequently transverse incision, carefully dissected and almost got out except just at the end of pea-shaped mass. Sac opened into by chance rendering removal difficult. Such a tumour removed from [?] eye caused it to fall down, as though it had communicated. Rest, antiphlogistics, inflamma-

tion subsided. In 8 days presented himself, wound healed, almost no scar. Thinks it arose from malar bone, confirmed by Mr. Walsh of Edinburgh.

Series of tumors removed from a lady. Gleetomatous of scalp. A curved or straight knife through tumor, allow wound to bleed, open another and came back to 1st. Skin has ulcerated and tumors may be *drawn* out. Pearly in appearance. 4 latter not here. Has removed as many as 16 from a gentleman.

Tend to run in families.

“Tumor from anus external”

Dr. Moore: Much itchininess or pain?

A very firm tumor. Snipped off with scissors, cold water applied.}

{Rough minute book:
TWENTY-FOURTH MEETING
April 12th, 1862

President chair, Drs. Stewart, J. C. Ferguson, Patterson, Moore, Browne, S. Reid, Dill, McMechan, Bryce, Smith, D. Moore.

Minutes read and signed.

Dr. S. Reid read notes of a case of aneurism of thoracic aorta (arch) opening into pleural sac and peritoneum.

Dr. Reid remarked that two effusions of blood had occurred.

President: True aneurism. Full coats. Rupture of middle coat and internal. After rupture of remaining coat and a dissecting aneurism of coats of œsophagus formed.

Dr. Browne read a paper on congenital cataract. Milky cataract and giving [exit?] to aqueous humor. 2 or 2¼ to read—see 4 to 4½ glasses.

Dr. Reid proposed Dr. J. C. Ferguson 2nd and passed unanimously That the issue of the annual balloting papers for the election of officers of this Society be deferred for one week later than the usual period.}

{Rough minute book:
TWENTY-FIFTH MEETING
April 19th, 1862¹

President chairman, Drs. Dill, J. C. Ferguson, Cuming, Bryce Smith, Johnston, D. Moore.

Dr. D. Moore for Dr. Pirrie shewed specimen of atrophied kidney, in Bright’s disease, in a girl of 7 years of age.

¹ [These rough notes are labelled March 22 but they are found between those for April 12 and those for April 29, and differ in content from an earlier set of notes also labelled March 22.]

Moved by Dr. Ferguson and 2nd by Dr. Dill That the ballot papers time of issuing be deferred till such time as the President and Council may think fit. Passed unanimously.

Dr. Ferguson read notes of laryngitis ultimately requiring tracheotomy.

President: Thought case proper for tracheotomy or laryngo-tracheotomy. 3rd or 4th rings above or below, there we must go, above azygos lobe of the thyroid body. Cut down to trachea, whether to wait to see if venous hemorrhage will cease after few seconds, hemorrhage as full as ever. All veins of head and neck were charged with blood. 42 years of age, cricoid and two upper tracheal rings very cartilaginous or partially ossified. Laryngo-tracheotomy, rings so hard as to be held open with difficulty for tube to be inserted, so that if the operation be successful the patient will probably suffer from some bronchitis or pneumonia after.

Operation as in strangulated hernia should be early, as there is a much more favorable chance for life, as in such cases there is 1st poisoning system by venous blood, 2nd a depressed irritability of lungs. An early operation will obviate this. The inner tube in the tracheotomy tube should not be longer than the other as it excites the patient’s trachea and causes coughing and irritation on each introduction after cleaning.

Dr. Dill—Case of scirrhus of mamma. Girl 22. 17 months ago first began. A small gland in axilla beginning to appear it was decided on removal. As to chloroform, it should be given freely and rapidly at first, the anæsthetic effect is better produced. Removed [?].

Dr. Murney—Case of scirrhus. 47 years of age, originated on surface of gland and involved deep surface of rim. Dr. Dill in substance of gland.}

{Rough minute book:
TWENTY-SIXTH MEETING
April 26th, 1862

President chair, Drs. Stewart, Browne, Patterson, J. C. Ferguson, Dill, Bryce Smith, Arnold, Cuming, W. MacCormac, S. Reid, Bryce, J. Moore, Johnston, Cantrell, Mulholland.

Resolved that the following notice be sent the members of the Society ...

The President for Dr. Pirrie brought forward case of acute rheumatism.

Dr. Ferguson asked cause of death.

Dr. Moore—Case of compound fracture.

Dr. Moore—Case of fibrous tumour
Diagnosis through [os?], ligature, twist.}

Belfast Clinical and Pathological Society

Ninth Session: 1861–1862

President Henry Murney

COMPILER'S NOTE

The above was the last clinical meeting of the Belfast Clinical and Pathological Society as, on the following day, 30 April 1862, it held a joint meeting with the Belfast Medical Society¹ and formed the Ulster Medical Society. The Ulster Medical Protective Association was also deemed to have taken part in the amalgamation² but seems not to have been specifically represented.

Records
Of the
Ulster Medical Protective Association

1859–1862

INTRODUCTION

The Ulster Medical Protective Association was set up in 1859 with the objects “to protect the interests of the profession, in the admission of its members; to sustain the status of qualified Practitioners, and to watch over, and, if desirable, to promote such legislative measures as may seem generally beneficial.”

Unlike a modern body such as the Canadian Medical Protective Association, it did not offer any indemnity to the individual practitioner.

The Belfast Medical Society had taken an interest in wider professional matters and in the seven sessions up to April 1859 had considered the reform of the profession, the Medical Charities Act, the standard of professional education for the medical officers of the Navy, Dr. Gay's dismissal from the Royal Free Hospital, London,¹ and the activities of the Irish Medical Association. It had joined the latter in October 1855 and paid the annual subscription of one guinea for at least that year and the following.

That it was the Society's intention to continue in these activities is shown by Surgeon Browne's remarks in his presidential address in June 1857 in which he said “Should the necessity again arise, as it likely will, this association will still take the lead in contending for our common interests, and in arousing the spirit of our brethren to the assertion of our inalienable rights.”² Despite this, only two years later Browne was taking the lead in setting up the Ulster Medical Protective Association and it is likely that he and his fellow-promoters could see that having a separate body with the potential for a wider membership would allow them greater freedom of action.

The original records of the Association are missing but many of its meetings were reported in the newspapers of the day and these have been extracted and are placed below in chronological order.

The reports get briefer as time goes on and cease after the annual meeting on 9th May 1861. The reason for this is not apparent: perhaps the Association lost momentum, perhaps it no longer wanted the publicity or perhaps it was no longer deemed newsworthy. That it was not dissolved altogether is

shown in the newspaper reports of Professor J. C. Ferguson's presidential address to the Ulster Medical Society in 1862 where it was acknowledged that the Ulster Medical Protective Association had joined with the Belfast Medical Society and the Belfast Clinical and Pathological Society to form the new Society; and Dr. Robert Esler's comments in 1886 that the Association was still active up until the amalgamation and stating that its last meeting was in May 1862.¹

There are two references after 1862 which suggest that even though the association amalgamated with the Ulster Medical Society, it still had some residual autonomy. The first is a comment by Dr J. S. Drennan in his presidential address of 1866 in which he says “Those, however, who may wish to enforce the law against unqualified practitioners, will find facilities for doing so in the Medical Protective Society, which is amalgamated with our own.”² The second is a proposal by the Medical Officers of Banbridge Union that they should send copies of some resolutions dated 21 May 1868 to the “Ulster Medical Protective Association”.³

The Ulster Medical Protective Association amalgamated with the Belfast Medical Society and the Belfast Clinical and Pathological Society to form the Ulster Medical Society.

TO THE MEMBERS OF THE
MEDICAL PROFESSION IN ULSTER.
Dublin Medical Press July 20 1859

Gentlemen and Brethren—The time has arrived when it becomes our imperative duty to wipe away a reproach that has long been attached to our profession, and to overcome that *vis inertia* which has rendered inoperative our inherent strength. This is to be done alone by union and hearty cooperation.

In Great Britain and several districts of Ireland, medical men have formed themselves into protective associations, and thus, already, have achieved considerable good, as every one who has watched the progress of medical reform must have observed. We might instance the amendments effected in the Medical Registration and Vaccination Acts, and the successful opposition given to several intended legislative measures, all of which would, more or less, have interfered with the rights of our profession. We might also refer to the concessions recently granted to the medical officers of the army and navy, and the contemplated improvements in the English Poor-law Administration, as severally indicating the value of the determined, persevering, and united efforts in the attainment of any claim based upon undeniable rights, and carrying with it popular sympathy—a sympathy, we may remark, which is ever afforded to any cause which rests its demands upon unquestionable justice.

No reform can spontaneously take place; the aggrieved parties themselves must seek to have their grievances removed, hence the medical profession should not imagine that the disabilities under which they undoubtedly labour can be remedied, unless they take not only the first, but the most energetic steps, and act with unanimity and perseverance. Inasmuch as there are professional wrongs, and that hearty coöperation is absolutely necessary to have them redressed, and seeing, likewise, what has been done by united action in other places—so much to their honour and credit—surely, it is not only prudent, but our imperative duty, to join with and assist our brethren in other districts of Ireland and in England in prosecuting our just claims, and in protecting those rights which every member should earnestly prize, and with which the usefulness, the respectability, and the influence of the profession are so intimately connected. With these views, therefore, a society—“The Ulster Medical Protective Association”—has been formed; a provisional committee has been appointed; a code of rules has been framed. In its name, we earnestly solicit the hearty coöperation of the medical practitioners of the North of Ireland, and invite them to enrol themselves members of the Ulster Protective Association.

And here it may be necessary to explain, that, while this association is quite independent of the

Belfast Medical and Pathological Societies, it cannot in any measure, be antagonistic to them. They are principally intended to foster and stimulate professional and scientific pursuits. The new association is entirely a protective one, desirous of enrolling in its ranks every registered practitioner of Ulster, and designed to act in concert with the Irish Medical Association in all matters affecting the general welfare of the profession. Such an association is urgently demanded. Disunion has caused our naturally inherent strength to be inoperative; apathy has allowed our rights to be disregarded, trampled on, or wrested from us. Jealousies have not only lessened our influence, otherwise powerful but have even injured us with the public, so deeply our debtor; for it is obvious that just in proportion as we act with harmony and maintain our position, so will our worth and status be valued and recognised.

The beneficial operations of a Medical Protective Association are not confined to any branch or class of the profession—they alike extend to the highest and reach the humblest member. Every one is concerned, directly or indirectly, in all matters that affect the general interests of the body; and it is, therefore, the solemn duty of all members to see that nothing shall be done which can interfere with its usefulness, honour, or influence. The best interests of society, as well as our personal advantage, demand this individual watchfulness—this coöperation; for it may be justly assumed that, whatever elevates and improves our profession confers a benefit upon the community at large.

We trust we have said enough to induce every person whom we address to join our association; and, as we feel satisfied that it is his paramount duty to do so, we look forward with confidence to the time, not far distant, when the entire profession shall be united in the furtherance of our common cause—then, and not till then, shall we be able to contend successfully for our inalienable rights—then, when the honour and importance of our body are maintained by ourselves, the community must assign to us our proper status, and our usefulness and our services shall be duly estimated and adequately acknowledged.

J. C. FERGUSON, A.M., M.B., Chairman of Prov. Com.
SAMUEL BROWNE, M.R.C.S.E., Secretary, Pro tem
Belfast, June 30th, 1859.

RULES OF THE ASSOCIATION.
Dublin Medical Press July 20 1859

1. That the society now embodied shall be named "The Ulster Medical Protective Association," to the membership of which all registered Practitioners shall be eligible.
2. That the objects of the Ulster Association shall be to protect the interests of the profession, in the admission of its members; to sustain the status of qualified Practitioners, and to watch over, and, if desirable, to promote such legislative measures as may seem generally beneficial.
3. That from and after the 1st of September, 1859, all admissions to membership shall be by ballot.
4. That the annual subscription of members shall be 5s., payable in advance, and shall be due on the first day of May in each year.
6. That the first general meeting of the association shall be held in Belfast, on the first Thursday in September next, when the office-bearers shall be elected. This meeting shall be called by a circular, addressed to each member.
6. That the officers of the association shall be a resident chairman, central committee, consisting of twelve town members, an honorary secretary, and a treasurer, along with three representatives from each county in Ulster. The chairman and one-third of the members of committee shall vacate office each May, but shall be re-eligible at the annual election.
7. That the annual meeting of the association shall be held in Belfast early in May in each year, for the election of office-bearers, and the transaction of general business; such meetings to be called by public advertisement in the newspapers.
8. That at each annual meeting a report from the committee shall be presented to the association, detailing the proceedings of the committee and prospects of the society; the treasurer, likewise, shall submit to the meeting a statement of accounts, duly audited.

EDITORIAL ON NON-QUALIFIED PRACTITIONERS
Belfast Daily Mercury 26 July 1859

A prosecution took place the other day, before a London Police-office, for the purpose of endeavouring to abate a nuisance which is very general, not only in England, but in this country.

By the 40th section of the Medical Practitioners Act, it is enacted, "that any person who shall wilfully and falsely pretend to be, or take, or use the name or title of a physician, or surgeon, or licentiate in medicine and surgery, bachelor of medicine, surgeon, or general practitioner, or apothecary, or any name, title,

addition, or description, implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine or surgery, or a practitioner in medicine, or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding £20."

A Mr. Samuel Nunn, who carried on business in Lambeth as a chemist, druggist, and dentist, had also the word "surgeon" painted artistically over the door, and also on a square of glass in the window. There was no doubt as to his having practised as a surgeon, and that he had no qualification whatever either as a surgeon, physician, or apothecary.

Dr. Ladd, honorary secretary to the London Medical Association, said he examined the printed copy of the register of the properly qualified medical men he then produced, and could not find the name of the defendant in it, and the absence of the name from it was deemed by the act itself a proof of disqualification. He had been to the house of the defendant, and over the door was the number "8," with the word "Surgeon" in large letters; then the name "S. Nunn, Dentist." There was painted on a square of glass in the window the word "Surgeons," the letter "s" being a very small one; and where it could be scarcely perceived, "Prescriptions carefully made up."

The inscription was such as to lead any ordinary person to suppose that Mr. Nunn was a surgeon, and made up prescriptions.

John Owen, a carpenter, residing in Kennington-lane, said that a short time ago he met with an accident and cut his hand, and was induced to go to the shop of the defendant for advice, from seeing the word "surgeon" on the door. He also asked the defendant if he was a surgeon, when he nodded his head in such a way as to lead witness to believe he was. He then examined his hand and arm, and made him up a bottle of lotion, for which he charged him a shilling.

Mr. Humble, a surgeon in the London-road, with whom the defendant had lived as an assistant, was called, and proved that he had no qualification beyond that of a chemist."

On such a state of facts, the London Medical Association instituted proceedings, as they were bound to do, for the protection of the public, and the Magistrate convicted the defendant in the very slight penalty of 40s, and 28s costs—a most inadequate carrying out of the Act.

Now, we are credibly informed that in Belfast, indeed throughout the province, there are a great number of unauthorised practitioners, who drive a profitable trade by butchering, and poisoning, and drugging to death the unfortunate people who are imposed upon by their pretensions. What is our local Medical Society about, that it is not watchful over the interests of the profession and of the public, by instituting proceedings against such persons? The leading

bodies in Dublin have been proverbially neglectful of their duties in this respect; and the local societies have now under the new act ample power in their own hands.

LETTER TO THE EDITOR
Belfast Daily Mercury 27 July 1859

Sir,—In reference to some remarks which appear in a leader of to-day's *Mercury*, relative to the "great number of unauthorised practitioners"—"in Belfast and throughout the province"—"who drive a thriving trade by butchering, and poisoning, and drugging to death the unfortunate people who are imposed upon by their pretensions"—I am happy to inform you that a Medical Protection Association for Ulster has been organised, and will soon be in a position to deal with the gentry in question, and to watch "over the interests of the profession and the public, by instituting proceedings against such persons."

Thanking you for having drawn public attention to this matter, I have the honour to be your obedient servant,

Samuel Browne, R.N., M.R.C.S.E.,
Secretary to the Ulster Medical Protection
Association, *pro tem.* Belfast, 26th July, 1859.

NOTICE TO MEDICAL PRACTITIONERS
Belfast News-Letter 22 August 1859

The PROVISIONAL COMMITTEE of the ULSTER MEDICAL PROTECTIVE ASSOCIATION beg to remind practitioners who have received the "ADDRESS TO THE MEDICAL PROFESSION OF ULSTER," that they should send their names and subscriptions to the Acting Treasurer, Dr. PATTERSON, of DONEGALL SQUARE, BELFAST, before THURSDAY, the 1st of September on which day the first meeting of the Society will take place.

(By order)
WILLIAM M'GEE, M.D.,
Chairman, *pro tem.*
SAMUEL BROWNE, M.R.C.S.E.,
Honorary Secretary, *pro tem.*
Belfast, 18th August, 1859.

NOTICE TO MEDICAL PRACTITIONERS
Belfast News-Letter 30 August 1859

The FIRST GENERAL MEETING of the ULSTER MEDICAL PROTECTIVE ASSOCIATION will be held at the GENERAL HOSPITAL, Belfast, on THURSDAY, 1st Sept., at Twelve o'clock Noon.

Members of the Medical Profession are invited to attend.

(By order of the Provisional Committee)
WILLIAM M'GEE, M.D.,
Chairman, *pro tem.*
SAMUEL BROWNE, M.R.C.S.E.,
Hon. Secretary, *pro tem.*
Belfast, August 29, 1859.

FIRST GENERAL MEETING
Belfast News-Letter 2 September 1859

Yesterday, the first general meeting of the Ulster Medical Protective Association was held in the Library of the General Hospital. There was a large attendance of the members of the medical profession.

Among those present were Dr. M'Gee, J.P.; Surgeon Browne, Dr. Patterson, J. Pirrie, M.D., Surgeon J. S. Dickson, Surgeon Wilberforce Arnold, Surgeon William Hanna, Surgeon William S. Kennedy (Comber), Staff Assistant-Surgeon R. M. Acton (Barracks), Surgeon Harman (Moneyslane), Dr. Rankin (Kirkcubbin), Dr. M. MacCormac, Dr. John Lavery (Maghralin), Surgeon James L. Connor (Moira), Surgeon William M'Gee, Surgeon Gribben, John H. Halliday, M.D., Robert Stewart M.D., H. Murney, M.D., Cunningham Mulholland, M.D., Alex. B. Filson, M.D. (Portaferry), J. Seaton Reid, M.D., Daniel Murray, M.D., Surgeon Henry Whitaker, Surgeon W. Warnick, William Aickin, M.D., J. C. Ferguson A.M., M.B., etc., F. Heeney, M.D., Henry M. Johnston, M.R.C.S.I., Archibald Dunlop, M.D. (Holywood), M. M'Gee, M.D., Thomas Charles S. Corry, M.D., Harrison Hanna, M.R.C.S., John S. Drennan, M.D., Christopher S. Black, M.D., J. W. S. Smith, M.D.

On the motion of Dr. M'Gee, J.P., seconded by Surgeon Browne, Dr. Stewart took the chair.

The Chairman said—Gentlemen, it is an unexpected honour conferred upon me to be called upon to preside over this highly-respectable, influential, and large meeting of our brethren generally. You are all aware, however, by printed circulars, of the object of this Medical Association for Ulster, which is now about to be formed; and this being its first general meeting, our respected secretary *pro tem.*, Surgeon Browne, will explain to you more fully—he being better acquainted with all the details than I am—the objects of the association. I am sure one and all of us are only activated by the one feeling and desire, and that is to uphold the due independence, and status,

and respectability of our common fellowship—and that every one amongst us will feel that any individual in any way harshly used by authorities or otherwise, that we will all feel it as affecting ourselves, and aid the association to the utmost of our power in seeing that justice shall be done to that individual. Ay, so acting, and by bringing ourselves together as one man, we will be doing an essential service, not only to ourselves as individuals, but to the public at large. I will now call upon Surgeon Browne to state the objects of the association.

Surgeon Browne stated that he had received letters of apology from the following persons, who were unavoidably absent:—Dr. Thorpe, Letterkenny; Dr. Babbington, Londonderry; Mr. M'Greevey, Antrim; and Mr. Thelford, Portaferry,

Dr. Filson (Portaferry)—This is dispensary day with some of those gentlemen.

Surgeon Browne—In a very few words, I may introduce the association to your notice, and to the notice of the public, because I think it is well the public should know exactly what position this association intends to assume—not one at all aggressive to the public, as some people seem to think, but one protective of the public, as it is held to be protective of ourselves. You are aware, gentlemen, and I wish the public to be aware, that, for a long time, there has existed in England a Medical Association of Great Britain. In this country also we have had now, for six or seven years, an Irish Medical Association in existence, which numbers now somewhere about 200 members. The membership of that is obtained by paying a certain subscription, and two years back they asked us to join them by the paying of a certain sum. There are the Carrick-on-Shannon, the Cork Medical Protective Association, numbering about eighty members, the Fermanagh, the Limerick, the South-Eastern, and the Wexford Association. These are all in connexion with the Irish Medical Association. However, up till a recent date we have had no connexion with it even collaterally, and we may call this a collateral connexion, seeing that the Medical Association [sic] of Belfast was invited to join them, which we did. I was deputed last June to attend a meeting of the association as representing the Medical Society, and all the medical officers of the medical district about us. I had pleasure in attending that meeting in Dublin from the strong feeling they had towards the gentlemen in the North—that feeling which they expressed at the meeting and afterwards at the dinner in the warmest terms; and I cannot now refrain from mentioning the names of the President, Dr. Whitaker, and the admirable secretary of the Cork Medical Association, Dr. Armstrong. They all appeared most anxious that we in the North should fraternise more than we had hitherto done, and hold out the right hand of fellowship; that we should meet them half way, meaning that we

should form an association in the North, and unite with them in Dublin, and with the other associations in the South and West. I promised, at that period, to bring the matter before my brethren in the North. I fulfilled that intention very shortly after I got into town here; and the details which I shall now lay before you will show what has been done. But before that, I wish for a few minutes to refer to the nature of the association. In the first place, as you will see by the prospectus, it has been stated that our intention is to unite for our mutual protection—for the benefit of the profession, and for the extension of the benefits of the profession to the community. By protection I mean we are to look after parties, and we intend to interfere with the Council of Education which now exists, and see that there is a proper scale of preliminary education for the profession. Secondly—To see that parties of proper character be admitted into the profession. And thirdly—To see that parties who are practising in our profession, but who do not belong to it, shall be at once brought under the law, and made amenable to justice. I believe that this is not only protective of ourselves, but protective of the community, because it is quite clear if we prevent a large number of men from going on through the various districts around us practising in our profession, who have no right to assume the name of medical men, and who have no education for the claim, that we are not only protecting ourselves, but doing a vast amount of good to the community, who are suffering from the interference of these uneducated persons who assume to themselves the name and dignity of doctors. I think, now, that these few words will explain to the public our position—simply to protect ourselves, and also to protect the public. There is no doubt the public are our debtors, and we are debtors to the public in a large measure—we live by them, and while we expect that they will do what is right towards us, we are bound to do good towards the public and to protect them. There is but one other observation that I wish to make regarding the association, and it is this—one of our resolutions goes on to state that we shall be in connexion with the Irish Association. Now it will be, I think, for this meeting to determine on what would be the best way to amalgamate with the Irish Association. There is no doubt that union forms the basis of strength, and that if the Ulster Protective Association joins with the Irish it will be better and stronger than if we remained disunited. At the same time, the Provisional Committee have guarded themselves from that, and have resolved to act as an independent association, except, of course, when a matter affecting our independence arises—such as the introduction of a Bill to Parliament—when it would be necessary to co-operate; whereas many things might arise of a local nature in which we don't need the assistance of the Irish Association, and would require only to be

brought under the cognisance of our own society. Hence, although we are united with the Irish Association, we should also see that we have ourselves so much of independence that we can act on our own behalf without consulting the Irish Association. I think there are no other remarks that I need trouble you with. I will now read to you the various minutes that, from time to time, have taken place at the meetings of the Provisional Committee. Surgeon Browne then read the minutes of the various meetings of the Provisional Committee [not available], and the following address and rules [given above]:—

Dr. M'Gee, J.P., in moving the adoption of the minutes, said—After the statement you have heard from Mr. Browne, I need scarcely detain you by bringing forward any argument—even if argument were necessary—for the formation of such an association. It is to me a matter of surprise that such an association has not long been established. If we had taken the example set us by other learned professions—such as the Bar—we would have done our duty to the public, and our duty to ourselves long ago. It is established for the benefit of us all, young and old; but I would have the youngsters to remember that it is especially for their benefit it has been established. When so many grey heads recommend the establishment of such a course, I think their advice is surely worth something. We have seen in England from day to day the advantages of such an association. We have heard of successful prosecutions, and of the benefit of them. And if we look at home, we see, on the other hand, what we may term the unjust persecution of our profession; and we feel that there should be some person or persons to stand forward and assist them—to defend their rights, and to defend the rights of the profession. With such examples before us we should no longer permit ourselves to be idle in this matter, and to have it said, instead of leading we have been led. It is our misfortune that in this matter we have been preceded by others. We should now set the example, but it is never too late to do well, and, under these circumstances, I think I can best consult the feelings of the meeting by, without any further observations, moving the resolution.

Dr. Filson (Portaferry)—I have very great pleasure in seconding the resolution. I only wonder that we have been so long coming into the field to form this association. I think it was rather discreditable to the medical gentlemen of Ulster not to have had such an association long since. We have seen the noble efforts which have been made on behalf of the profession by the Cork Medical Protective Association; but, as has been said, “Better late than not all.” I trust and hope that the matter will now be entered upon with resolution and determination—(hear, hear)—and that the members of the profession throughout Ulster will give their support to the gentlemen who have under-

taken the formation of the association, and who are exerting themselves in carrying out the object had in view; for the greater the number who join the association the more powerful will be its influence. (Hear, hear.) I would be sorry there should be any member who would hold back from joining this association. All members of the profession will be benefitted by the steps which will be taken by the association; therefore, I trust all will feel it to be their duty to aid in the efforts put forth. (Hear, hear.) There will be great difficulty, I know, in some of the country members attending the meetings, but I trust they will come forward manfully and give the association their best support. (Hear, hear.) I have great pleasure in seconding the motion of Dr. M'Gee.

The Chairman then put the motion, which was passed unanimously.

Surgeon Browne—Our Treasurer pro tem. Dr. Patterson, will now state to you the position of the association.

Dr. Patterson stated that 112 members had paid their subscriptions and joined the association, and he hoped many others would join it. The subscriptions amounted to £28. The number was made up as follows:—County Antrim, 65 members; County Down, 18; County Tyrone, 4; County Monaghan, 3; County Fermanagh, 1; County Derry, 8; County Armagh, 7; County Cavan, 1; County Donegall, 4; total, 112.

ELECTION OF OFFICERS.

Surgeon Browne suggested that the officers elected then should remain in office until May, '61, as it would hardly be worth while to have an election so soon as May next. They might override one of their rules in this instance.

Dr. J. C. Ferguson, Professor Queen's College, begged to move that Dr. M'Gee, J.P., be elected chairman of the committee.

Surgeon Browne begged to second the motion.

The proposition was put from the chair, and passed unanimously.

Surgeon Browne—Our next business is to elect twelve members of committee to represent Belfast; then to elect a secretary and treasurer, and then three members of committee from each county.

It was then arranged that the members for Belfast should be—Surgeon Browne, Dr. Seaton Reid, Dr. J. C. Ferguson, Dr. Stewart, Dr. Murray (Ballymacarrett), Surgeon Dickson, Dr. Heeney, Dr. C. Black, Dr. Murney, Dr. Wheeler, Surgeon Tring, and Dr. Halliday.

Dr. Michael M'Gee begged to move that the twelve gentlemen named be elected as members of the committee.

Dr. Johnston begged to second the motion, which was put and passed unanimously.

Dr. Seaton Reid begged to move that Surgeon Browne be elected as Honorary Secretary. They

Ulster Medical Protective Association

1859–1860

Chairman William M'Gee

would all admit that it was not a very lucrative appointment, but he hoped Surgeon Browne would be satisfied with the honour. (Hear, hear.)

Dr. Corry had great pleasure in seconding the motion.

The motion was put and unanimously agreed to.

Surgeon Browne—I am thankful to you all for the honour you have done me in electing me as Secretary. It is a troublesome post, but I will do my best to forward the interests of the association. (Hear, hear.) I will endeavour to advance the interests of the profession and the advantage of the public. I trust the younger members will not expect too much from the association. There are many persons who take up little grievances, and who might expect the association to interfere; but there is nothing more easy than for an association to burn their fingers. (Hear, hear.) It is better for members not to expect too much. The association will require to have the premises as clear as possible before they act. I wish the younger members to bear this in mind. As you have elected me as Honorary Secretary, it is now necessary that you fill up my place in the committee by another Belfast member. I beg to move that Surgeon Warwick be elected as a member of the committee.

Dr. Dickson begged leave to second the option, which was put and agreed to.

Surgeon Browne—When the association was temporarily formed, Dr. Patterson kindly consented to act as Treasurer, and I think we cannot do better than to vote him to that office now. (Hear, hear.) I know the great ability with which he discharges his duties, as he has been treasurer to another society. I have great pleasure therefore in moving that he be the treasurer of this Association.

Dr. Michael McGee—I beg to second the motion.

The proposition was then put and passed unanimously.

Dr. Patterson returned thanks in a few words, for the honour which had been done him.

The names of the three gentlemen from each county, from which three medical men had joined the association, were then nominated to be members of the committee. (The names will be found in our advertising columns.)¹

[These were: Antrim.—Dr. O'Connor, Ballycastle; Dr. Kidd, Ballymena; Dr. M'Kee, Randalstown. Down.—Dr. Filson, Portaferry; Dr. Jameson, Newtownards; Surgeon Connor, Moira. Derry.—Dr. Babbington, Londonderry; Dr. Cavin, Coleraine; Dr. Maxwell, Moneymore. Armagh.—Dr. Patten, Tandragee; Dr. M'Kinstry, Armagh; Dr. MacLaughlin, Lurgan. Donegal.—Dr. Thorpe, Letterkenny; Dr. Eames, Dunfanaghy; Dr. Baggott, Malin. Monaghan.—Dr. Fleming, Carrickmacross; Dr. Young, Ballybay; Dr. Donaldson, Clontibret.

Tyrone.—Dr. Scott, J.P., Aghnacloy; Dr. Neville, Dunganon; Dr. Fleming, Omagh. Cavan.—Dr. Taylor, Bailieborough; Dr. M'Gahan, Kingscourt. Fermanagh.—Dr. Maxwell, Derrylin.]

Surgeon Browne suggested that the committee have power to add the names of gentlemen for Cavan and Fermanagh when they might join.

It was agreed that the names of the first who became members of the association from these counties, should be added to the committee.

Dr. Pirrie begged to move that the gentlemen mentioned be appointed members of the committee to represent the different counties.

Dr. Rankin begged to second the motion, which was put and agreed to unanimously.

Dr. Corry thought it was a matter for consideration whether they should not appoint a secretary for the country district. He merely threw it out as a suggestion.

Surgeon Browne remarked that each member of the committee for the counties was a kind of secretary. It would be the business of each of them to communicate upon local matters to the committee, for it was not to be expected that they could always attend from a distance.

THE DUNMANWAY UNION CASE—DR. WALL

Surgeon Browne then read a communication from the secretary of the Cork Medical Protection Association with regard to the case of Dr. Wall, medical officer of Dunmanway Union, who was dismissed by sealed order of the Poor-Law Commissioners, and a medical gentleman sent down from Dublin to take his place, as none of the local medical gentlemen would accept of the position, believing, as they did, that Dr. Wall has been harshly treated. He (Surgeon Browne) thought the case had not been very clearly stated, even in the document which he had read, and he considered the best course for that association to pursue would be to refer the matter to the committee to do as they might think best after getting more detailed information on this subject.

Dr. M'Gee, J.P., in a few remarks, begged to move that it be referred to the committee.

Dr. Pirrie begged to second the motion. The statement which had just been read was very imperfect. He thought they should take no action on it at present.

After some remarks from Dr. Filson, Dr. Heeney, Dr. Dickson and others, the motion of Dr. M'Gee was put and agreed to.

REGISTRATION OF
BIRTHS, DEATHS, AND MARRIAGES.

Surgeon Browne had to lay before them a copy of the Bill brought in last session of Parliament, by Lord Naas and the Attorney-General for Ireland for the registration of births, deaths, and marriages. There

¹ [Belfast Newsletter, 1859, 2 September, page 1.]

was one clause in the Bill which would affect the profession. He referred to the 15th clause which provided that if a medical man neglected to send to the registrar a certificate of a death within eight days, he should be liable to a penalty of 40s, while he was to receive nothing for doing it. That was a penal clause which they should not allow to pass without pointing out the hardship of it. He anxiously desired to see a registration Bill brought in and passed into law; the Bill for Ireland to be framed on the same principles as the law of registration in England. The Board of Guardians had decided upon petitioning the government upon the matter, and when he brought it before the Board, he referred to some points in the Bill which appeared to him to be unconstitutional. But what touched upon their interests most was the fifteenth clause, and they should watch the passing of any law upon the subject, as the present government seems likely to bring in a Bill upon it, for he saw it named in the list to be brought in next session.

Dr. Pirrie moved that the Bill be referred to the Committee.

Dr. Kennedy—I beg to second the motion.

The Chairman then put the resolution, when it was passed unanimously.

Dr. Dickson moved that the Chairman vacate the chair, and that Dr. M'Gee, the newly-elected Chairman of the committee, be called thereto.

Dr. M'Gee, having taken the chair, said it became his duty to return them thanks for the honour which they had done him. He had been so often called upon to return thanks for honours done to him that he really did not know what to say without repeating what he had said on some previous occasion. He had not the slightest idea when he entered the meeting that he should be called to that office, for he naturally believed that it would have fallen upon one who occupied a higher position; but as they seemed to think that he could be of some service, he was willing to take the office, and do all in his power. (Hear, hear.) They had, however, lightened his duties considerably, by the appointment of such an invaluable honorary secretary as Surgeon Browne. (Hear, hear.) As to the formation of that association, he had long thought such was necessary. They had seen, time after time, how the public had made demands upon their time, which was their capital, and the public had again and again forgotten the services rendered to them. In Belfast they had some noble exceptions. The Board of Guardians, at a time when services had been rendered by the medical gentlemen, for which the Board of Guardians then had no power to pay, afterwards proposed to take steps to have them remunerated, and the medical gentlemen refused to accept of anything, and were satisfied with the thanks of the Guardians. He hoped such services would never be required again under such circumstances; but, if their

services were required by the public, the latter should now know that these services must be paid for. Their association could do much to advance the interests of the profession. The Registration Act was one which they could use their influence in urging the Legislature to pass, and it would be of great benefit, not only to the entire public, but would materially serve the profession. Every death occurring in the county would have to be certified, stating the disease which caused it, by a medical gentleman, and no certificate would be received from any but those properly registered; so that it would tend to put down quacks who were not members of the profession. Then, the association would look after having a change made in that clause which affected them personally. If they had had an Association at the time the Vaccination Act passed, they would have had such improvements made in it, and would not have left its provisions such a tax upon the time of medical officers without any commensurate reward. He did not know what the Registration Commissioners did for the protection of the registered members of the profession. They received heavy fees from the members of the profession, and he thought they should look after the interests of the profession better than they did. He would not detain them longer, but begged again to thank them for the honour done him. (Applause.)

Surgeon Browne wished to say that the Hospital Committee, having been applied to, had kindly granted the use of the library for the association to hold its meetings in it.

Dr. Dickson then moved that the best thanks of the meeting be given to Dr. Stewart for his conduct of the chair. No man deserved their thanks more than Dr. Stewart, for, although he had received an appointment which removed him from active practice, yet he never failed to lend his aid to forward the interests of the profession. (Hear, hear.)

Dr. Filson seconded the vote of thanks, which was put, and passed with acclamation.

Dr. Stewart having acknowledged the compliment, the meeting separated.

MONTHLY MEETING

Belfast News-Letter 14 October 1859

The usual monthly meeting of the Ulster Medical Protective Association was held yesterday [13th October 1859], at their room in the Belfast General Hospital. There was a large attendance of members on the occasion. Dr. Heeney occupied the chair. The Honorary Secretary, Surgeon Browne, apologised for the absence of Dr. M'Gee, J.P. He then reported that he had put himself in communication with the Secretary of the London Medical Registration Society, and with the counsel of the Ulster Association, J. M. Thompson,

Ulster Medical Protective Association

1859–1860

Chairman William M'Gee

Esq., Barrister-at-Law, with the view of carrying out the provisions of the Medical Act against unqualified practitioners.

The Treasurer (Dr. Patterson) reported that the association now enrolled 124 members.

Dr. Hume, of Crumlin, was balloted for, and un-animously elected a member of the association.

The Secretary then brought the case of Dr. Harman, of Ballyward, under the notice of the committee, and he was directed to write to that gentleman, and to convey to him their warm sympathy. The committee, at the same time expressed it as their opinion, that the Poor-law Commissioners had not rendered Dr. Harman justice, in accordance with the evidence, as published in the newspapers.

The Secretary was directed to notify to all the members the propriety of their bringing under the notice of the committee the names of any unqualified persons practising medicine in their several districts, or assuming to be physicians or surgeons without any legal license, that the committee may take prompt measures for punishing such pretenders, as counsel may advise. The secretary was also directed to ask the opinion of their counsel whether medical men holding Government medical appointments, as in the Queen's Colleges, were not, according to law, compelled to register, and to inquire if any certificates granted by them could be held as valid until they had so registered? The last report of the Poor-law Commissioners having been brought under the notice of the meeting, the members unanimously expressed their strong disapprobation of the portion which refers to the appointment of non-professional men as inspectors for medical purposes, and they stated their determination to join with the other Protective Associations to prevent the fulfilment of an intention so opposed to justice, to the rights of the medical profession, and the welfare of the community. Surgeon Browne stated that he had already been in correspondence with Dr. Armstrong, the indefatigable Secretary of the Cork Association, on the subject. It was one which he regarded as of great moment, and which called especially for the notice of every Medical Protective Association; for the profession might rest assured that if the Commissioners' views were once carried out, the dispensary doctors would be in a much worse position than they now occupy, though that is, in many respects, a very unenviable one. The Secretary was then requested to watch the proceedings regarding this question very closely, and to bring up a special report on the subject for the next meeting of the committee.

COMMITTEE MEETING

Belfast News-Letter 11 November 1859

Thursday [10th November 1859], at twelve o'clock, a meeting of the committee of this association was held in the Library of the General Hospital, Dr. M'Gee in the chair.

The following were balloted for and admitted members of the association:—Surgeon Shaw, Grey-abbey; Dr. White, Downpatrick; Surgeon Harrison, Ardglass; Dr. Wm Browne, Derry; Surgeon Phillips, Ballygawley.

A question arose as to the admission to membership of a gentleman who was known to be duly qualified, but did not appear on the list as registered, and after some discussion, it was resolved to let the matter remain over until the gentleman could be again communicated with.

Dr. Patterson announced that the association now comprised 130 paid members, besides some who had not yet paid their subscriptions.

Surgeon Browne said they numbered nearly 140 altogether.

Dr. Patterson said he had been requested to ask if the degree of M.B. from the University of Aberdeen entitled the holder to assume the title of Doctor. It was objected that some gentlemen had "Doctor" upon their doors, when they were only M.B.'s.

Surgeon Browne said the title of "Doctor" had always been given to them by courtesy.

The Chairman thought that this was a case in which they should not interfere. They had in Belfast three or four gentlemen of high standing who were M.B.'s, and it would be preposterous to interfere. When any of them were asked about it, they should direct the applicant to apply to the Council for Ireland. The title of Doctor was given to M.B.'s by courtesy just as that of "lord" was given to the sons of peers; but, if they went into a court of law, they would not get that title.

Dr. Murney said that in Trinity College there was an examination for M.B., and a year after the degree of M.D. was given, upon the payment of the fees, and without any second examination.

Surgeon Browne read a letter from a gentleman who wished to be enrolled if possible. He stated that his name was not on the register of this year owing to his passing after it was made out. He observed that their association was about to give quackery a death-blow. He suggested that the Association should send persons throughout Ulster to find out unqualified persons and have them brought to Justice immediately. (Laughter.) He submitted the names of four persons without any qualification, who styled themselves "doctors and general practitioners," and were practising in his neighbourhood. Surgeon Browne went on to

say that he believed the writer of this letter was registered.

It was agreed that his election be adjourned until the certificate of registration be forwarded.

The general and bye-laws of the London Medical Registration Society were laid on the table, and were ordered to be referred to a subcommittee, to consider whether any of them should be incorporated in the rules of the Ulster Medical Protective Association.

Surgeon Browne said that he, as secretary, had received two letters from their honorary counsel. One was relative to professors in Queen's Colleges, &c., and the other called the attention of the association to the fact that, in a county of Ulster, two members of the medical profession had applied for spirit licenses at a late Quarter Sessions. The Chairman of the county on that occasion felt it his duty to represent the matter to the honorary counsel of the association, and desired him to bring it before the secretary, thinking that it was really a great hardship upon the profession that such a thing should occur. Perhaps the best course would be to refer the matter to the sub-committee.

The Chairman said that when such a report was going before the public, they should understand that men of high rank in Belfast, wine merchants and others, were obliged, for the purposes of trade, and in order to keep their stock correct, to have a retail license. It might just happen that these men, being druggists, wished to be licensed for the sale of spirits of wine, and it would be hard to stamp them as the keepers of dram shops, although they did deal in drachms, until they saw exactly what were the facts of the case.

Dr. Murney—Are they both members of our association?

Surgeon Browne—No; but they are both registered.

Dr. Patterson—It is very disgraceful to the profession.

Surgeon Browne said they had applied to members to send in the names of parties who were practising illegally. He had got some names, and would lay them before a sub-committee; but it would be well for the public to understand that since the association had been established a good many of them had taken to flight from Belfast, and others were trying through subterfuge to escape the observation of the society. He might inform those parties that so sure as the society existed they would be hauled up in a very short time before the public. He understood that one of these men had partly obliterated the name on his premises so that it could not be read, but was still practising and receiving fees. He intended to submit a case to counsel to know how far they could go under the 40th clause. He was quite sure that a man acting, in the capacity of a general practitioner could be

taken up and brought before the magistrates, although he might not assume the title of doctor, surgeon, or anything else.

The Chairman said he had heard of a case lately in England, where the man did not style himself a doctor, but the conviction seemed to have been founded upon his having administered medicine and received money. The 40th clause provided that "if any person should willingly and falsely pretend to be," or take or use the name or title of physician, &c., he should, upon summary conviction, pay a sum not exceeding £20. Now, the first line, he thought, included such cases as were referred to by Mr. Browne. The question was, whether prescribing and giving medicine, and taking payment therefor, would not be pretending to be a practitioner in medicine.

Dr. Wheeler said that sometimes the unqualified man was partner with a qualified.

Surgeon Browne said that in that case the unqualified man was not protected by the qualification of the qualified man, and he would find it to his advantage either to leave off practising or take a qualification.

Mr. Warwick, mentioned a case in which an unqualified practitioner sent in a bill for 30s, and when it was objected to as excessive the payment of it could not be enforced.

Surgeon Browne said the public should understand clearly that in all cases they were protected against quackery, for, if they did not like to pay the money, the quack could not recover it.

The matter then dropped.

Surgeon Browne said he had been requested to bring up a report on a subject of much interest to the profession. In the year 1857 a Bill for the amendment of the Medical Charities Act was introduced into the House of Commons by the Chief Secretary for Ireland, Mr. H. Herbert, having been prepared upon the recommendation of the Poor-law Commissioners, and by the 14th section it was proposed to empower the inspector appointed under the Poor-law Act to discharge the duties of inspectors under the Medical Charities Act, notwithstanding that they might not possess the medical qualification required by this latter Act. That was of course opposed at the time, but in the report of the Commissioners for 1859 they recommended that their inspectors be empowered to act as medical inspectors, and that the medical inspectors should be empowered to act under the Poor-laws, adding that one inspector with medical qualification would appear to be sufficient for the whole of Ireland, except in special cases when others would be employed. He asserted that it was totally impossible for a non-medical man to exercise proper inspection over dispensaries, but the medical inspectors could discharge efficiently all the duties of inspectors under the Poor-law Acts, and if the Commissioners required them all to be medical men, he

was sure the profession would not object; but if they brought forward any such provision again, he, if still a Poor-law Guardian, would give it his most strenuous opposition.

The Chairman said the Commissioners themselves had frequently found it necessary to employ medical men to report on cases requiring professional knowledge; and, in fact, a layman could not perform the duties of inspector under the Medical Charities Act. He was only surprised that they had been so economical as to employ only four or five medical Inspectors for all Ireland. They should have one for each county, and then, let them diminish the number of ordinary Poor-law Inspectors if they pleased.

Surgeon Browne read a letter from the Secretary of the Southern Association, Dr. Armstrong, stating that they intended to make some move in the matter.

The Chairman said that if the Poor-law Commissioners saw there was going to be opposition, they would not press it forward.

It was agreed, on the motion of Dr. Stewart, that a memorial be presented to the Poor-law Commissioners, and to the Chief Secretary for Ireland, Mr. Cardwell, praying that in any proposed Poor-law Amendment Act, the provision for setting aside medical inspectors be not inserted.

THE CASE OF DR. WALL

Surgeon Browne said he had received from the Secretary of the Irish Medical Association copies of the memorial presented from that body to the Poor-law Commissioners, in reference to the case of Dr. Wall, late medical officer of Dunmanway Union, together with the reply thereto. In the memorial, the Council of the Medical Association of Ireland begged to submit for the consideration of the Poor-Law Commissioners some observations on the circumstances connected with the inquiry relative to the death of Jeremiah M'Carthy in the Dunmanway Workhouse Hospital. The Council had been struck with deficiency in the conducting of the inquiry by the Poor-Law Inspector, as shown in the omission to take either the evidence of the deceased's relatives, or that of the porter of the house, which, as circumstances had since shown, might have altered the views of the Poor Law Commissioners. The Council then referred to the inquest held on the body, and proceeded to comment upon the letter of the Commissioners to the Board of Guardians. Having noticed the state of deceased on admission to the hospital, after the lapse of twenty hours from he received the injury, the Council remarks that under such circumstances, although a surgeon might suggest an operation as the only means of giving any chance of life, yet he might feel reluctant to press it on the patient or his friends, when they so strongly expressed their opposition to such a proceedings; this reluctance would be

increased by the conviction that the chances of saving the man's life had been reduced by the delay in bringing him to the hospital. The Council, while they would not deny that blame might be attributable to Dr. Wall in some points; still it appeared to them that the punishment with which his errors had been visited, had been out of proportion to the offence. In conclusion, the Council respectfully ask a withdrawal of the sealed order against Dr. Wall, or a re-opening of the case to admit further investigation.

The following reply was returned:—

“Poor-Law Commission Office, Dublin,
14th Oct., 1859

Sir—The Commissioners for Administering the Laws for Relief of the Poor in Ireland have received the statement relating to the case of Dr. Wall, addressed to them, and signed by you, as Chairman of the Council of the Medical Association of Ireland.

In reply, I am to state that the Commissioners do not feel called upon to enter into correspondence with the Council of the Medical Association, as to the manner in which they discharged their duty in the case of Dr. Wall.

The Commissioners must, at the same time, observe to you, in your capacity of medical officer of the Bray Dispensary district of the Rathdownen Union, that you have addressed to them language which, in their opinion, is not befitting your position as an officer performing a public duty, under the superintendence of the Commissioners. In a matter which no way regards the discharge of your own duties, or the administration of the same in your own district, you state that there has been a great deficiency in the conduct of the late inquiry in Dr. Wall's case on the part of the Poor-law Inspector; you advert, also, to defects in certain documents addressed by the Commissioners to the Board of Guardians, and to their Inspectors in the subject of this case; and you give it as your opinion, that, although blame is attributed to Dr. Wall in some points, the punishment with which his errors have been visited has been out of proportion to the offence.

You are, doubtless, at liberty to form your own opinion of the merits of the case in question from such information as you may possess regarding it; but as the Commissioners cannot consistently with their position enter into explanation with you in defence of their proceedings they submit to your consideration the propriety of not addressing them in future on the subject of their official conduct in any matter which does not concern the administration of the law in your own district. There is a part, however, of your communication of which the Commissioners feel constrained to take more serious notice; they allude to the opinion which you have voluntarily conveyed to them regarding Dr. Wall's conduct in taking active steps to effect the removal of a man, with a com-

pound commiserated [*sic*] fracture of the leg, extending into the knee joint, from Dunmanway Workhouse to an Infirmary at Cork, a distance of forty miles, for amputation; such being the desire of his friends, under circumstances which you describe as making amputation (even in the workhouse) a hopeless expedient. Regarding this part of Dr. Wall's conduct, you observe—"One can readily understand that in such a case from which no favourable issue was then to be expected, the practitioner might be induced to assent to almost any course which appeared grateful to the patient's friends."

The expression of such views by the medical officer of a dispensary district makes it incumbent on the Commissioners to warn him that, if in any similar case to that of Jeremiah M'Carthy he should put in practice, under a dispensary ticket, a course analogous to that pursued by Dr. Wall, the consequences would be very serious to himself, as the Commissioners would, without hesitation, adopt the same measures in his case as those which they adopted in the case of Dr. Wall.

(By order of the Commissioners,
To Dr. Whistler, Bray")

Surgeon Browne, in continuation, said that that letter was characteristic of the Board from which it came. It was an exhibition, he would not say of petty tyranny, but of the course which the Commissioners pursued towards those over whom they thought they had some power. The memorial was not the act of Dr. Whistler, but of the council of which he was the chairman. A single word disrespectful to the Commissioners was not used. There was an admission made which he (Surgeon Browne) would not have made—that Dr. Wall might have been somewhat to blame; but the memorial did not call for the severe language made use of by the Commissioners in their reply. It was not to Dr. Whistler they addressed that language, but to the whole Irish Association; and he trusted the Irish Association would know how to reply to them.

Dr. Stewart said that so far as he knew the facts of the case, Dr. Wall was not to blame in any way whatever,

The Chairman said he regretted that the Commissioners should have seen fit to write such a letter. They had now been told for the second time that their sealed order, when contrary to law, could not be carried out. When they called on Dr. Wall to resign, and when he did resign, that should have been a settlement of the question, and they should not have punished twice by dismissing him under sealed order, after he had been unanimously elected by the Guardians. He was sorry the Guardians did not take their stand on that point and try the question with them.

It was moved by Surgeon Browne, seconded by Dr. Patterson, and agreed to. "That, having heard the

address from the Council of the Irish Medical Association and the reply of the Poor-law Commissioners, this meeting cannot but regret that the Commissioners should so far have forgotten the relative position of themselves and Dr. Whistler as to have written in the incourteous terms addressed to him."

An adjournment then took place.

EXECUTIVE COMMITTEE
Belfast News-Letter 9 December 1859

Yesterday [8th December 1859], the Executive Committee of the Ulster Medical Protective Association met in the Library of the General Hospital, the President, Dr. M'Gee, J.P., in the chair. The other members present were—Professor Ferguson, Dr. O'Connor, Ballycastle; Drs. Murney, J.P.; R. Stewart, Hospital for the Insane; Patterson, Halliday, Dickson, Heeney, Warwick, and Surgeon Browne.

After the transaction of the ordinary business, and the election of Dr. Bernard, of Dungannon, and Surgeon Patrick, of Carrickfergus, as members,

The Secretary brought under the notice of the Committee the meeting of the profession in Ireland, which had been summoned by the President of the Irish Medical Association, to take up certain questions of great interest to the entire medical body of this country. These questions embraced the consideration of the amendments required in the Medical Charities (Ireland) Act: the Poor-law proceedings relative to Doctor Wall's case at the Dunmanway Union: the manner in which Medical Poor-law inquiries are conducted; the letter addressed by the Poor-Law Commissioners to the Chairman of the Council of the Irish Medical Association, &c., &c. Of course these were very important matters for the consideration of the profession, and he quite concurred with the views put forward in the letters he had just read from Dr. Babington, Londonderry, and Dr. Thorpe, Letterkenny, relative to the necessity of sending representatives on behalf of the Ulster Association to the general meeting, called for the 15th inst.

The Chairman and several other members expressed similar views—the Chairman and Dr. Stewart referring specially to Dr. Wall's case, which they considered was one of very great hardship.

Professor Ferguson moved, and Dr. O'Connor seconded, that "The Chairman of the Society, Dr. M'Gee, J.P.; and the Honorary-Secretary, Surgeon Browne, be appointed a deputation to the meeting of the profession at the Limerick Junction, on the 15th instant, and that these gentlemen shall then appear in the name and on behalf of the Ulster Medical Protective Association."

The motion was put and passed unanimously.

The Secretary was directed to put himself in communication with the President and Secretary of the Irish Medical Association, and to lay the replies before a sub-committee to meet on the evening of Tuesday, the 13th inst.

The committee then adjourned.

IRISH MEDICAL ASSOCIATION
AGGREGATE MEETING AT THE
LIMERICK JUNCTION HOTEL
Belfast News-Letter 19 December 1859

An aggregate meeting of the members of the medical profession in Ireland, convened by Dr. Mackessy, of Waterford, President of the Irish Medical Association, was held at the Limerick Junction Hotel, on Thursday night, at half-past seven o'clock. The principal object of the meeting of the meeting was to consider the case of Dr. Wall, late dispensary doctor in the Dunmanway Union, and the course which had been adopted by the Poor-law Commissioners in the case

At half-past seven o'clock Dr. Mackessy took the chair. The Chairman, in opening the proceedings, said that he felt greatly pleased to see present so many gentlemen holding a high rank in the profession. There was one circumstance to which he felt called upon to allude, and which he himself thought of with much pleasure—he meant the attendance at that meeting of a deputation from the Ulster Medical Protective Association, a society which was doing much to advance the position and maintain the high character of the medical profession. They were deeply indebted to those gentlemen for their attendance that night, for, if it had no other good result, it would make it plain that, they were all united and determined not to relinquish their rights without a struggle. The spirit of union was what they most stood in need of, and as long as they were animated by it they might rest assured that nothing could injure their position. It was incumbent upon them to endeavour to preserve this feeling, and they might rest satisfied that as long as they remained united they had nothing to fear from the attacks of any board, no matter how powerful. (Hear, and applause.)

Dr. Harvey, of Cork, moved the first resolution, which referred to the conduct of the Poor-law Commissioners in the case of Dr. Wall as an arbitrary exercise of power, and said that before alluding to the terms of the resolution which he felt honored by having been called upon to propose, he felt bound to express his opinion that the meeting which had assembled that night could not be said to be called together by uncreated motives so much as by a sense of public justice. The large number of medical men who had attended, and many of whom were wholly unconnected with the Poor-law Commissioners,

could not be said to be influenced by self-interest, or by resentment. They were there to affirm a principle, and to complain of what they conceived to be an injustice. Their object was to maintain their independence, and to protect their rights. In this view alone were any observations necessary. They had to complain of undue and improper interference, and of a desire to trample upon the profession; and standing in the position which they occupied, he felt that they would not yield to oppression or injustice. The gentlemen who uttered that document of which they complained—and he would not mention their names, which he wished he did not know—were well aware of the injury which they were attempting to do to the medical profession; and specially to those who were to a great extent under their authority, and unfortunately held office merely during their pleasure. All the members of the profession who for the present filled the position of dispensary doctors or doctors of workhouses were persons of education and principle; and, except in respect of pay, were in no way inferior to those under whose power they were placed. (Hear, and applause.) He did not feel warranted in making further remarks, as he had only taken the opportunity of expressing an individual opinion, and he was anxious to listen to what would be said. (Applause.)

Dr. Jacob, of Maryborough, seconded the resolution, which he felt to be a very important one. As had been said, the question was not merely a medical one; it was a subject upon which every right-minded man would entertain but one opinion. The complaint of that meeting rested upon the broad grounds that an attempt had been made to dictate and to overbear. He had no personal feeling or no animosity to gratify, but he came forward believing that the letter of the Commissioners was a pitiable exhibition of intemperate official feeling. They made an effort to crush and injure a gentleman who, unfortunately for himself, was in their power. But the public would not stand their conduct, nor would the medical profession in Ireland suffer it to pass unnoticed. Too temperate an appeal had been made to their good sense and love of justice, and therefore the Commissioners turned round and acted with unwarrantable severity in a particular case. The medical profession were, therefore, compelled to come forward at that meeting and assert their rights, and were perfectly determined that the public should be made acquainted with the circumstances of the particular case of which they complained. He spoke in the presence of many gentlemen who were employees of the Poor-law Commissioners, and he asserted that the rules of the Commissioners, by which they intended that every dispensary doctor should act, were impracticable and could not be carried out. The Commissioners knew this to be the case; but whenever any gentleman was obliged to transgress these impracticable rules, or

became obnoxious to them in any way, they had only to crush him with their sealed order, which they made out while sitting in their easy chairs by their council table. (Hear, hear.) These were facts, as every person present knew, and he appealed to public opinion. They knew the rules to be bad, though they did not set about remedying them in the best manner, but perpetuated the injustice, which they had lately practised in the case under consideration that night. At Cootehill they visited a gentleman with their displeasure, simply because the severity of his duties and the demand upon his time, made it perfectly impossible for him to visit the hospital before twelve o'clock. This was only another case to add to the number of the acts of injustice which the Poor-law Commissioners had committed. He thought they ought to be given some advice and shown their mistake. They had not good medical advice at present; for he believed that if their medical advisors were bold and fearless, and determined to maintain the rights of the profession, there would be less cause of complaint against the Board. He (Dr. Jacob) believed that the different districts in Ireland should send a committee, consisting of delegates from each, to point out to the Commissioners the mistakes which they were so frequently committing. Could any man of common sense, who understood anything whatever of the duties of a physician, say that he deserved reproof or censure because he did not attend an hospital before twelve o'clock, when he lived in a large district, and might on any occasion be called away to attend a case of childbirth, or some patient in the agonies of death? But the Commissioners need not care for the justice or injustice of their rules. They made regulations, and they seemed determined to carry them into effect regardless of consequences, for they possessed an irresponsible power which enabled them to crush every person who became disagreeable to them. What was the course which, under the circumstances, should be adopted? They should battle for their rights at all hazards. He, as an Irishman, was afraid of no man, and would not be deprived of his privileges or submit to insult. The case of Dr. Wall would, he was sure, be spoken of and explained by some of the speakers to follow him. He had only to deal with the principle that medical men would not stand to see their body attacked by unfair means. He had great pleasure in seconding the resolution. (Applause.)

Dr. Rawdoon Macnamara supported the resolution. He felt it impossible to sit quiet and not assert what he felt to be the privilege of every medical man. He believed that they had just cause for complaint in the fact that the Poor-Law Commissioners had refused to listen to their fair and temperate appeal. They had asked for an investigation upon the same principle as those which were held in courts of law, where no decision was arrived at except on legal evi-

dence. The Poor-Law Board was not, surely, superior in authority to the Courts of Queen's Bench or Chancery, but they assumed a more arbitrary authority; and they had been written to and asked to suspend their judgment in the case of Doctor Wall until they had learned the additional evidence which could be offered, but they replied, stating that they would not hold any communication with the members of the Irish Medical Association. If, however, they had merely contented themselves with this, and had gone no further, he ventured to say that the meeting at which they were that evening assembled would never have been held, and that nothing farther would have been done than remonstrate with them upon their injustice. But they treated the chairman of that association as if he were merely representing his own opinions, and not those of the great number of medical men who formed that, useful and influential society. They sent him a message to the effect which he had stated. It was true that some gentlemen had told him some days ago that it was not the intention of the Poor-law Board to convey such an impression; but, however, their words remained, and it was impossible to weaken their meaning. (Hear, hear.) He confessed that he was more pleased to see that a number of the gentlemen present were under the control of the Poor-law unions than he was to notice that his friend Dr. Jacob, and many others who were wholly independent of the Poor-law Board, were in attendance. He felt sure that the *Ægis* of the British Constitution would be thrown over those gentlemen; and, in any event, they had shown more wisdom in coming forward to confront injustice in a manly way than they would have done by shrinking back from avowing their rights. There was more hope for the confident and self-reliant than for those who crouched under the whip. He felt that these complaints would not that night be made in vain; but that they would find their way to responsive hearts all through Ireland, and would awaken popular indignation and sympathy, that the cry would not be uttered in vain by any British subject—"*Civis Romanus sum*" (Loud applause.)

The resolution was then put and carried.

Surgeon Browne, of Belfast, moved the next resolution, which was to the effect;—"That a petition should be prepared and presented to Parliament," He begged to thank the meeting for the kind manner in which he had been received, and to assure the chairman, who had alluded in terms of congratulation to the union between the medical men of the North and South of Ireland, that on the part of the members of the medical profession in Ulster, and the society they had recently established, everything would be done to keep up the feelings of good-will and sympathy, He was ashamed at a former meeting to be obliged to put himself forward as the representative of the profession in Ulster; but now a society had been formed,

numbering one hundred and forty good men and true, and he felt honored at being made the instrument of conveying to the gentlemen of the Southern districts that night the sentiments of reciprocity and kindness to them which animated the Ulster Medical Protective Association. (Hear, hear, and applause.) He was sure from what had been said they were all determined to maintain their privileges and immunities—not as members of the medical profession only, but as British subjects, and as guardians of the sick poor; for if they were injured or their influence shaken, what would become of the poor? They had inalienable rights, and they would not give them up hastily, without some attempt to defend them. He did not wish to detain the meeting with any views of his own, as he believed that the whole question would be ably argued. He merely put forward the broad principle on which they should act, and he hoped to see their struggle for their privileges terminate successfully. (Applause.)

Dr. Ryan, of Tipperary, seconded the resolution, and referred in a few observations to Dr. Wall's case. He thought Cork should take the lead.

Dr. Harvey suggested that on the committee to prepare the petition should be one gentleman from every deputation who attended that meeting (Hear, hear.)

The resolution was put and carried.

Dr. M'Gee, President of the Ulster Medical Protective Association, felt great pleasure in having the opportunity afforded him of speaking at so influential a meeting in defence of the rights of his brethren of the medical profession in Ireland. He hoped that upon such a subject as they were considering, the union between the medical men of the North and South of Ireland would last long; and he might tell them that the members of the association over which he presided had some time ago determined upon a separate petition of their own. (Hear, hear.) Upon Sir John Arnott having made certain representations to the Poor-law Board some time ago, an inspector was sent down, to make inquiry into the matter. This was the course which upon such occasions the Commissioner uniformly adopted; but it should be remembered that the men upon whom, as inspectors, this arduous duty devolved, were wholly ignorant of the subjects with which they had to deal, and the manner in which they should be handled. He was thoroughly conversant with the workings of the Poor-law and the Medical Charities Act, having been connected with the Poor-law system for many years, and he saw the errors into which they ran by mistaking the manner in which the duties of medical inspectors could be discharged. It was surely to be supposed that to discharge these duties a man required some professional knowledge; but the Commissioners acted as if they believed this was unnecessary in gentlemen who had to deal with

the most important matters. Their mistakes arose, partly from the desire to economise, and also to a very great extent from ignorance. He spoke of the Poor-law Commissioners with all due respect, and he had no desire to say anything which might not appear to be founded strictly upon fact; but he did think that, as an almost irresponsible body with unlimited power, and a great field for its exercise, they were sometimes led into errors which it would be as well for themselves and the public they could avoid. They had now a *locus penitentiae* offered them, and they ought to come forward to remove the slur which had been cast upon their character, and begin a new and better system of administration. (Applause.)

Dr. Johnson, of Kilkenny, briefly seconded the resolution, which was put and carried.

Dr. Howlet moved the next resolution. He regretted that the resolution which conveyed the sentiments of the meeting with respect to the conduct of the Poor-law Commissioners was one which required to be put at that meeting. It was to be lamented that their conduct exposed them to the censure of all right-thinking men both in and outside the profession. Dr. Martin, of Portlaw, seconded the resolution, which was carried.

Dr. Armstrong, of Cork, said he had a paper which was drawn up very kindly by Dr. Johnson, of Kilkenny, and which stated fully the whole case. He would read it by the permission of the meeting. Dr. Armstrong then proceeded to read the paper, which stated that in Dunmanway, in January last, a young man received a severe fracture in the leg. He was brought to the workhouse hospital and placed under the care of Dr. Wall; but though the fracture was very severe, he would not consent to amputation; Accordingly, he remained there without having the limb amputated, owing to his constant refusal to submit to the operation. After some time his friends asked that he should be sent to Cork, and he himself was anxious to go, and he went against the desire of Dr. Wall. The Commissioners complained of Dr. Wall's conduct in not having the leg amputated, and in permitting the patient to go up to Cork to die as he did from the effects of the injuries he received, and they sent a letter to the union calling upon Dr. Wall to resign. He did so and a new election took place, at which, as no other gentleman offered himself, he was re-elected. Some time afterwards another letter arrived from the Commissioners, calling upon him to give up the situation to which he was re-elected. He did so, but at the request of the guardians attended to the health of the inmates temporarily. Again came a note threatening a sealed order, and stating that the Commissioners would send up some gentleman from Dublin to take the office. In the meantime patients died, but notwithstanding the frequent letters of the Guardians the Commissioners seemed determined not to permit

Dr. Wall to be re-elected, and in this matter they acted against the commonly permitted practice of re-electing certain officers of a union.

The Chairman stated that he had had an interview with Mr. Cardwell, and complained of the great injustice done Dr. Wall in inflicting three separate punishments upon him. The Chief-Secretary received him courteously, and listened to him with attention. He also remarked upon the strange circumstance, that though the Commissioners deemed Dr. Wall incompetent, they permitted him to discharge the duties of medical officer for five months after the circumstance complained of occurred. He also alluded to the case of Dr. Whistler. He (the Chairman) thought he might state at this point, that he had received upwards of a hundred letters of apology from gentlemen who were not able to attend.

After some further discussion, Dr. Meade said that it seemed hard that a gentleman who, even if he had been wrong, had only committed a slight error, should be dealt with so harshly. It appeared that the guardians had commenced a subscription for Dr. Wall, and it would be well, perhaps, if others would follow their example. He thought the whole subject should be taken up and attended to by the College of Surgeons.

Dr. O'Brien, of Ennis, moved the next resolution, also referring to the case of Dr. Wall. The principle of the resolution he believed to be one which was embodied in the Parliament of Great Britain, and which was the safeguard of the accused, protecting them from any conviction not founded upon evidence. He would like to know why, with respect to the members of the medical profession, the Poor-law Commissioners do not act upon this principle? Why were medical men punished in an arbitrary manner before it was established that they had made any mistake? The Poor-law Board often constituted itself into a Star Chamber to put down and to ruin a person who had done no real harm; but whom, perhaps, they believed guilty of a trifling indiscretion. As a person who was connected with the Poor-law Commissioners in the capacity of a medical officer, he had believed it his duty to come forward on such an occasion to express the opinions which he held. He believed the Board had an arbitrary and excessive power which should not be intrusted to them in a free country, and which enabled them to crush every one in their employ who happened to offend. (Hear.)

Dr. Bennett seconded the resolution, though a servant of the Commissioners.

Dr. Quinan moved the next resolution, appointing a committee to carry out the objects of the meeting.

Dr. Hanrahan seconded the resolution, which was carried unanimously.

Dr. Brown said that, as the business which related to Dr. Wall's case had been transacted, this was the

place to allude to some matters in connection with the profession which ought to receive the attention of such a meeting. He was very well pleased to hear Dr. Bennett declare that the medical profession were the guardians of the children of the poor. If they would look to facts they would see that from persons having such a duty to discharge it was necessary some petition in favour of making vaccination compulsory should issue, for something should be done to prevent the spread of a loathsome and most dangerous disease, which was now becoming more general than formerly. There should be a compulsory registration of births, in order to make it possible to have compulsory vaccination. (Hear, hear.) The person who was not vaccinated was a focus of contagion, and injured not only himself but his fellow-men. Again, the sale of poisons should be considered carefully, and something should be done to prevent people selling injurious and poisonous drugs, who understand nothing about them or their fatal effect. Dr. Brown concluded by moving a resolution to the effect that a committee be appointed to consider these various subjects, and to prepare a petition to Parliament, praying for an amendment in the existing law. (Hear hear.)

Dr. Magee seconded the resolution, which was carried.

Dr. Brown was then moved to the second chair, and the thanks of the meeting voted to Dr. Mackessy for his kindness in presiding, after which the proceedings terminated.

MANAGING COMMITTEE

Belfast News-Letter 13 January 1860 &

Belfast Daily Mercury 13 January 1860

Yesterday [12th January 1860], a meeting of the Managing Committee of the Ulster Medical Protective Association was held in the library of the General Hospital, when the President, Dr. M'Gee, J.P., occupied the chair. There were present—Dr. Patterson, Surgeon Browne, R.N.; Dr. Heeney, Dr. Halliday, Dr. Stewart, Dr. Black, and Dr. Murney, J.P.

Dr. Browne then read the minutes of the ordinary and special meeting of the association, and afterwards moved that they should be confirmed.

That motion was agreed to.

A ballot was then taken, and Surgeon Jeffers, of Cloughmills, was unanimously elected a member of the association. The Chairman remarked that that name made 134 paid members.

Dr. Browne asked had Dr. Patterson any report to make to the meeting?

Dr. Patterson—I may say that we have expended about £21, and that there are still £13 or £14 in hands.

Dr. Browne said it might be remarked that one of their rules was, that no gentleman could be elected a

member unless he were a registered member of the profession.

Dr. Heeney—Is that one of the rules?

Dr. Browne replied in the affirmative, and said that the society was not only a protective but was also a registration association.

The Chairman explained the law in reference to the case of a man whose name might not appear on the register, and who might have occasion to go to law for the recovery of any claim for professional services which he might have rendered. All he would have to do would be to register, and he would get a printed certificate signed by the registrar, showing that he was registered, and that certificate would be a legal document.

He would get the certificate without fee or reward. On the other hand, suppose a man's name was upon the register, it might be objected that the register was not legal evidence in itself; and in that case, he could get the certificate by applying for it and it would be legal evidence of his qualification.

Dr. Brown said that if a medical man wished to correct the register, it was only necessary for him to send his name and address to the registrar, Dr. Maunsell.

Dr. Halliday—And will the book not be received in evidence in a court of justice?

Dr. Patterson—It will not.

Dr. Browne—A case occurred the other day in England.

The Chairman—Some barristers admit the book, and others may not; but when you have the certificate signed by Dr. Maunsell, Dr. Browne or I can prove the handwriting.

Dr. Browne said they would recollect that, at the meeting of the association on the 8th of December, Dr. M'Gee and himself were appointed as a deputation to proceed to the Limerick Junction meeting. They were instructed by a sub-committee as to what course they were to pursue, and what views to advocate.

They had seen by the local papers that the report of that meeting at the Limerick Junction had been very kindly copied from those papers that had reporters there, and gentlemen could see that the proceedings were of a very satisfactory character, and that the interests of the profession, and especially those of the public, were advocated by the deputation, for they took care that the public should see that the profession were not only fighting for themselves but also for the public.

They found that the public were the parties who suffered most when medical men were assailed; and, consequently, the meeting passed a resolution which had been published, and to which he need not again refer. The deputation was kindly received, and the kindest feeling was expressed by the members of the

profession in the South and West towards the profession in the North, and a determination evinced to cooperate with them in every possible way. The next matter he had to bring before them was that he had forwarded to the General Council of Medical Education, and also to the Branch Council, copies of the memorial which had been prepared as directed, and he would read that memorial. He might, however, say that he had received letters from Dr. Hawkins and Dr. Maunsell, acknowledging the receipt of the copies, and also from Dr. Armstrong, Secretary of the Cork Association, to whom he sent a copy of it also. The memorial was as follows:—

“To the General Council of Medical Education and Registration in the United Kingdom.

Gentlemen—I have the honor to state that I am directed by the Ulster Medical Protective Association most respectfully to represent to you the propriety of having a separate medical register for Ireland, issued in 1860, as they believe that such a step would be a great boon to the profession in this country, as it would enable each member to have in his possession a copy in a cheap form, and of easy reference.

They consider that such a course is essential for the successful working of the Medical Act; and I may state that this was the decided opinion of the aggregate meeting of the medical profession of Ireland, held on the 15th instant, and before which I had the honor of submitting this important question.

Trusting that your honorable Board will give this subject your most favorable consideration. I have the honor to be, gentlemen, your very obedient servant.

Samuel Browne, Honorary Secretary.

Belfast. 28th Dec., 1859

P.S.—This association numbers 140 members, and represents about 400 practitioners. The meeting of the profession referred to represented all of the medical associations and the entire profession of Ireland.’

The next matter to be brought under the notice of the meeting was, that the memorial to the Chief-Secretary for Ireland had been forwarded, and a copy of it sent to the Poor-Law Commissioners; the latter had acknowledged the receipt of it, but there had had been no reply yet from Mr. Cardwell. The following is a copy of the memorial:—

“To the Right Hon. Edward Cardwell, M.P., Chief Secretary for Ireland, &c.

Sir—The Ulster Medical Protective Association having observed in the last report submitted to his Excellency the Lord Lieutenant of Ireland, by the Poor-Law Commissioners, that a suggestion formerly made relative to dispensing with the services of medical inspectors, under the Medical Charities Act, has again been set prominently forth, beg, through us,

most respectfully to state that such a course, if adopted, would prove most detrimental to the welfare of the sick poor, as, from experience, they are decidedly of opinion that the provisions of the Medical Charities Act can be efficiently carried out, alone, under the superintendence of medical inspectors. They would, therefore, humbly and earnestly request that any Bill which may be introduced into Parliament for amending the Poor-law and Medical Charities Acts, shall not contain the objectionable clauses suggested by the Poor-law Commissioners.

We have the honor to be Sir, your obedient, humble servants,

William M'Gee, M.D., Chairman.
Samuel Browne, Hon. Secretary.
Belfast, 4th Jan., 1860."

It would be seen from this memorial that the annotation was more anxious for the good of the public than for the benefit of the profession. There was just another memorial to the Branch Medical Council, on the question of vaccination which he would read:

"To the Branch Medical Council for Ireland.

The humble Memorial of the Ulster Medical Protective Association

Respectfully Sheweth—That memorialists, having had nearly two years' experience of the working of the Vaccination Act in this country, believe that, though it has effected much good, it has failed in accomplishing its intended measure of usefulness, in consequence mainly of its not containing any compulsory powers; they believe, therefore, that no measure for promoting vaccination, especially among the poorer classes, could prove effectual, unless it contained some compulsory provisions to meet the apathy and carelessness of many persons in this country.

Memorialists consequently believe that for this purpose the legislature should, in the first instance, pass an Act for the registration of births and deaths in Ireland, without which any law for compulsory vaccination, it is evident, could not be duly enforced.

That, viewing the question of vaccination as one of very great importance to the community, and believing that to the medical profession properly belongs the duty of pointing out to Government the necessity there is for a more comprehensive measure for promoting vaccination than now exists, memorialists call, most respectfully, but earnestly, upon the Branch Medical Council, as the legal representatives of the medical profession in Ireland, to urge upon the Government that a measure for compulsory vaccination, founded on an Act for registering births and deaths in Ireland, be introduced into the ensuing session of the Imperial Parliament.

William M'Gee, M.D., Chairman.
Samuel Browne, Secretary."

The Chairman thought the question of the sale of medicines by unqualified parties was highly injurious to the well-being of the public, and he had just prepared a short memorial to the Company of Apothecaries' Hall, Dublin, as he believed they had power, at least to some extent, to put a stop to the evil. The memorial was as follows:—

"To the Governor, Deputy-Governor and Directors of the Company of Apothecaries Hall of the City of Dublin.

The Memorial of the Ulster Medical Protective Association

Respectfully Sheweth—That, from the Act 31st Geo. III., cap. 34. as manifested in its preamble, and in sections 16, 18, 22, and 26, it was intended that your Corporation should take measures for preventing unqualified persons from preparing or vending medicines, or opening a shop or wareroom for the retail of medicines; that, having heard and believing that it has become a practice for grocers and other such dealers in various towns and villages in Ulster, to retail to any applicant laudanum and other medicines dangerous in the hands of the ignorant or ill-disposed, your memorialists now respectfully request Your Corporation to put in force the power vested in you by law, so that practices so dangerous to health or to life may be discontinued.

William M'Gee, M.D., Chairman.
Samuel Browne, Secretary."

The Chairman, after referring to the law on the subject contained in the memorial, said that the powers of the Apothecaries Hall as regarded the sale of poisons were limited, but that the committee had not thought it necessary in the memorial to go into the question of poisons.

Dr. Browne—In case we get a reply from the Apothecaries Company, stating that they have no powers in the case, what are we to do? Are we to petition the Government or memorial the Branch Council for Ireland?

Chairman—I think, then, that you should memorial the Medical Council, and petition Parliament too.

Dr. Stewart then moved the adoption of the memorial, and that it should be transmitted to the proper quarter.

Dr. Halliday seconded the motion, which was carried.

Dr. Heeney moved that a memorial should be prepared and forwarded to the General Council, to take steps for regulating and restraining the sale of poisons.

Dr. Patterson seconded the motion.

Dr. Browne then moved that the thanks of the meeting be given to the president, committee, end secretary of the Hull Medical Association for their

Ulster Medical Protective Association

1859–1860

Chairman William M'Gee

kindness in forwarding to them the report of their association for the last year.

Dr. Black seconded the motion.

The proceedings then terminated.

PUBLIC MEETING

Northern Whig, Belfast 10 February 1860

Yesterday [9 February 1860], a public meeting of this important association was held in the library of the General Hospital—William M'Gee, Esq., M.D., J.P., President of the Association, in the chair. There was a good attendance of members.

The Secretary (Surgeon Browne, R.N.) read the minutes of the previous meeting, which were confirmed.

NEW MEMBERS

The following gentlemen were unanimously elected members of the association Dr. M'Conkey, Downpatrick; Dr. M'Clintock, Raphoe; Surgeon Otterson, Magherafelt; Surgeon Frame, Comber.

The Secretary remarked that the strength of the association was pleasantly increasing. He hoped it would soon number 150 or 200 members.

He said that, in reference to the memorial sent by the association to the Dublin Council, regarding the separate publication of a medical register for Ireland, he had received the following reply:—

“Branch Medical Council (Ireland),
35, Dawson Street, Dublin,
20th January, 1860.

Dear Sir,—I have laid your letter and the resolution of the Ulster Medical Protective Association, stating the opinion of that body that the medical register of Ireland should be published separately from the general register, before this council; and I am directed to state that this branch council will bring the subject before the general Council; and, also, that the following resolution was passed by this branch council on the 23d February, 1859, viz.:—

Unanimously resolved—“That it is the opinion of this council that there should be a separate register, in alphabetical order, for England and Wales, for Scotland and for Ireland, respectively; as, in such form, the register will be more easy of reference, more correct, and more saleable, than if there be only one continuous alphabetical register for all; and that such registers may be bound together, or sold in separate parts, as required.”

I am also to inform you that this branch council recognises the importance of the subject of the memorial of the Ulster Protective Association, in reference to a measure for compulsory vaccination, and

will bring it under the consideration of the general council.—I am, yours, truly,

H. Maunsell, Registrar.

S. Browne, Esq.”

Secretary—The next communication I have is from the Chief Secretary, touching the appointment of medical inspectors, and is as follows:—

“Dublin Castle, 18th January, 1860.

SIR,—I am directed to acknowledge the receipt of a letter signed by you as chairman of the Ulster Medical Protective Association, and dated the 6th instant; and I am to acquaint you, in reply, that the question of medical inspection will receive full consideration in any Bill which may be introduced to Parliament on the subject.—I am, sir, your obedient servant,

Thomas Larcom.

William M'Gee, Esq., M.D., 1, Adelaide Place, Belfast.”

Secretary—The next is a reply from the Poor Law Commissioners respecting the same memorial to that which I sent to the Chief Secretary:—

“Poor Law Commission Office,
Dublin, Jan. 7. 1860.

Sir—The Commissioners for Administering the Laws for Relief of the Poor in Ireland acknowledge, with thanks, the receipt of your communication, dated the 6th inst., transmitting a copy of a letter which has been addressed by the Ulster Medical Protective Association to the Chief Secretary for Ireland, on the subject of the proposed Poor Law Amendment Bill.—(By order of the Commissioners),

B. Banks, Chief Clerk.

To Samuel Browne, Esq., M.D., Belfast.”

The Secretary also read the following communication, which explains itself:—

“Apothecaries' Hall, Dublin, Jan. 20, 1860.

Gentlemen,—I am instructed by the governor and court of directors of this hall to acknowledge the receipt of the memorial which has been forwarded, in your name, on behalf of “the Ulster Medical Protective Association,” requesting of the hall to exercise the powers entrusted to it for preventing unqualified persons from preparing and vending medicines, and retailing poisonous drugs.

The governor and court, in reply, beg to inform the association that their Act of Incorporation, “31st Geo. III., chap. 34,” limits their control to unqualified persons “who open shop or practice as *apothecaries*” but leaves the retail of drugs and poisons, with the single exception of arsenic, entirely unrestricted.

In reference to the evils referred to in the memorial, the governor and court are anxiously alive to their enormity, and have been exerting their influence with the Government to introduce a Bill into Parliament to restrict the sale of drugs and poisons to persons who shall be duly qualified and licensed for the purpose.—I have the honour to be, gentlemen, your obedient servant,

C. H. Leet, Sec.

To W. M'Gee, Esq., M.D., &c.; and S. Browne, Esq."

The Chairman said, all the association asked the directors to do was to exercise powers, which, it now appeared, they had not. However, they could reasonably go to Government with this document as evidence.

Dr. Filson (Portaferry)—The Apothecaries' Company tried the question, and were defeated.

Dr. Patterson—When did they try it?

Dr. Filson—Twenty or thirty years ago; and they never could succeed unless they could prove that the defaulters prescribed and compounded medicine as apothecaries.

Surgeon Browne—There is one thing certain, that we will have to take further steps; and, as the Apothecaries' Company is anxious to have it settled, application should be made at once to have a Bill brought in on the subject.

Dr. Dickson—If you mean a Bill to give the apothecaries further powers, I, for one, will oppose it.

Chairman—But it is not to give them further powers; it is merely to restrain unqualified persons from practising.

After some further discussion,

It was moved by Dr. Browne, and seconded by Dr. Filson:—"That, in consequence of the reply of the Apothecaries' Company, a petition be drawn up praying the Government to restrict the retail sale of poisons and drugs to duly qualified persons."

Chairman—We can then petition the Government with regard to the nature of the Bill.

THE MEDICAL CHARITIES' ACT.

The Secretary submitted forms of petitions sent from the Irish Medical Association, and the Cork Association, praying the Government for a more liberal policy towards the medical workhouse officers in Ireland

The Chairman said the power of the Poor Law Commissioners would have to be renewed this year, so that a very suitable opportunity would be afforded for asking Government to take the matter into consideration.

Dr. Stewart moved that the petition of the Irish Medical Association, with such alterations as a sub-committee to be appointed should devise, be sent to Parliament, and that copies be sent to the members

for the borough, with the request that they will support the prayer of the memorial.

Surgeon Warwick seconded the motion, which was carried unanimously.

The following were appointed a committee to draw up the memorial—Dr. M'Gee, Surgeon Browne, Dr. Patterson, Dr. Stewart, and Dr. Dickson,

An application was received from the Newry Chirurgical Society requesting that they might be admitted into the Ulster Medical Association on the condition that they would be allowed to preserve their distinctive character.

Dr. Michael Magee thought the matter could not be settled except at the annual meeting, and the secretary was requested to write to the Newry Chirurgical Society for a copy of the rules and objects of the society.

Dr. Patterson—They can only be admitted individually.

The matter was postponed.

UNQUALIFIED PRACTITIONERS

Surgeon Browne read a communication from a member of the association, requesting the body to take into their consideration the fact that a person is practising in Belfast, as a physician, who is not qualified.

Neither the name of the writer of the letter nor the person referred to were made public.

Dr. Patterson knew the person very well, and if he had prescribed, it was most improper. He had no right to prescribe, he was uneducated, professionally speaking, and should know as much.

The object of the association was the punishment of such people, and little quarter should be shewn them. He would move that the secretary be instructed to write to the person in question that, if he continues to prescribe, action will be taken.

This course was agreed to.

The Secretary brought under the notice of the Society a similar case, the offender being in the county Donegal. This was also communicated to the Association.

It was agreed that the person referred to should be communicated with, and that he be requested to send a reply, in which his qualification to dispense medicine will be set forth.

The meeting then terminated.

LETTER TO THE EDITOR

Dublin Medical Press 28 March 1860

THE MEDICAL ACT

Sir,—As the London Medical Registration Association have made a movement for the purpose of having an amended Medical Act, and as the Provincial and other

Ulster Medical Protective Association

1859–1860

Chairman William M'Gee

Medical Societies have been applied to for their views on the subject, perhaps you will allow me to lay before the profession, through the medium of the "Press," the suggestions which the Ulster Protective Association have made to their London brethren, permitting me, also, at the same time, to express the views I entertain regarding the Medical Act—views which I believe are held by nearly every one who has observed the inoperative nature of that measure.

Whatever the good intentions of the Legislature were in framing the "Medical Act," it is quite evident that these intentions have not been fulfilled. For if we believe that the promoters of that measure wished to benefit and protect our profession, to elevate and improve its status, we must admit that, for so far, their kind wishes have most signally failed.

To what then can we ascribe that failure? Mainly, I believe, to the fact that the Legislature, after many fruitless attempts to reconcile contending colleges and conflicting interests, passed a measure, the machinery of which is altogether too cumbrous and too expensive to work satisfactorily; or it may be that they to whom the working of that machinery was entrusted, do not comprehend it; hence the Councils, in despair I presume, instead of applying themselves to the reorganization of the profession, by the improvement of preliminary, and the equalization of medical education, so as, in time, to render our body uniform and its position more elevated, have frittered away their meetings—few and far between—in unseemly wranglings about paltry rights and the privileges of opposing colleges.

The whole procedure of the Councils, I contend, has been the very opposite of beneficial to those whom they represent and whom they were bound to protect. Their method of applying themselves to business proves that, in business matters, they are not practical men, and hence, after a very large expenditure of money, they have not only not benefited the public, or the profession, to the value of fifty pounds, but have made, I fear, an impression on the public mind that our body does not possess within it the element of self-government.

It is not, however, too late to mend: if the Councils will, with calmness and firmness, set to work continuously, and not at long intervals and by spasmodic fits; if they will remember that they are legislating for the profession of which they are the legalised head, but which they are bound to honour and advance—if they will regard a seat at the council board as one of the highest honour, and not a source merely of emolument—if they will take a delight in serving and consulting the interests of their own profession—and if they will permit the presence of the public press at their discussions; I say, if they will do all these things they may make the existing Act, even with its admitted defects, effect a vast deal of good; but if, on the

contrary, they pursue the course they have hitherto followed, I, for one, must believe that any measure so worked can secure little more than a mockery and a snare.

The following are the amendments for the Medical Act, suggested by the Ulster Medical Protective Association:—

"That the General Council be required to insist upon the degree of B.A. or A.M., as preliminary education, or the subjection of the candidate to an examination embracing a course of instruction equivalent to the aforesaid degrees. And that they shall take steps to equalise and render uniform medical education and examinations.

That the Councils shall appoint an Inspector, at a suitable salary, for each portion of the united kingdom, for the purpose of examining all establishments where drugs are compounded or sold by retail, and with power to destroy all impure articles.

That the Councils shall restrain all unqualified persons from retailing or compounding drugs, and that they shall establish regulations for the safe retail of all poisonous matters, or drugs.

That there should be clear evidence of identity, as well as of qualification, of all persons applying to be registered under the Act.

That the law should be so framed that the simple act of prescribing medically or surgically, with or without a fee, shall be considered an infringement of the statute, as being an assumption of a medical status, position, or title.

That upon any unqualified person having been proved to have prescribed, or pretended to be qualified, the onus of proving his title to practice shall be put upon him, as every registered practitioner can have a certificate of his registration by applying for it.

That the production of the Registrar's certificate shall be deemed sufficient evidence of a medical practitioner being duly registered.

That there should be greater facility for prosecuting and punishing offenders against the provisions of this Act than at present exist.

That, in addition to the general Register, there shall be published a separate Register for each part of the united kingdom at a cheap rate, so as to be procurable by every person desirous of having a copy.

That the 23rd Clause should be struck out of the Medical Act, as it countenances quackery in its worst forms, for it seems anomalous that an act which appears to be intended, and was ostensibly framed to protect the regular practitioner, should be made either openly or covertly to foster the lying systems of homœopathy, hydropathy, or the like."

I have the honour to be, Sir, your faithful servant,

Samuel Browne, Lic.K.&Q.C.P.I.,

Hon. Secretary Ulster Medical Protective Association.

Belfast, 19th March, 1860.

FIRST ANNUAL MEETING
Belfast Daily Mercury 11 May 1860 &
Belfast News-Letter 11 May 1860

Yesterday [10th May 1860] the first annual meeting of the Ulster Medical Protective Association was held in the Library of the General Hospital at 13 o'clock, Dr. M'Gee, J.P., President of the Association, in the chair. Amongst the other members present were—Drs. Pirrie, Patterson, Halliday, Stewart, Warnock, Murney, J.P., Browne, W. Arnold, Michael Magee, Johnston, Corry, Mulholland, Hayes,

Surgeon Browne: (Hon. Sec.) read the report of the first general meeting of the association held in last September, and also the following

REPORT OF COMMITTEE.

“Since the inauguration of the Ulster Medical Protective Association in September last, the committee has held ten meetings—two special and eight ordinary. There were, besides, several meetings of sub-committees for the purpose of business arrangements. The first act of the committee was to frame a code of bye-laws and a programme of business. Early in the month of October the honorary secretary was directed to put himself in communication with the Irish Medical and the Branch Protective Associations, as well as with the London Medical Registration Society, for the purpose of effective co-operation in matters affecting the general interests of the profession. Since that time several opportunities have arisen which enabled the various societies to act in friendly concert.

On the 15th of December, a deputation, consisting of the chairman and honorary secretary, attended the aggregate meeting at the Limerick Junction, a most important assembly of the profession, to represent this association. As a result of the Limerick Conference, the committee sent memorials to the General and Branch Medical Councils on the subject of a separate register for Ireland; to the Chief-Secretary for Ireland, on the necessity of retaining medical inspectors under the Medical Charities Act; to the Branch Medical Council for Ireland, on the subject of compulsory vaccination; to the Apothecaries-hall of Dublin, on the sale of medicine by unqualified persons, and on the required restrictions in the retail of poisons.

The following petition to Parliament, signed by more than two hundred medical practitioners in Ulster, and which was presented by Sir Hugh McCalmont Cairns, was sent forward in March, and a circular was addressed by the secretary to every member of Parliament for Ulster, requesting each to support the prayers of the petition. (This petition has already been published.)

A communication having been received from Dr. Ladd, the Secretary of the London Registration Association, relative to suggestions for amendments in the Medical Act, the following were sent from this association by the committee:—

1. That the General Council of Education be required to insist upon the degree of B.A. or M.A. as preliminary education for medical aspirants, or the subjection of the candidate to an examination embracing a course of instruction equivalent to these degrees; and that they shall take steps to equalise and render uniform medical education and examinations.
2. That the councils shall appoint an inspector for each portion of the United Kingdom, at a suitable salary, for the purpose of examining all establishments where drugs are compounded, or sold by retail, and having power to destroy all impure articles.
3. The councils should have power to restrain all unqualified persons from retailing or compounding drugs, and they should establish stringent regulations for the safe retail of all poisonous matters or drugs.
4. That there shall be clear proof of identity, as well as of the qualifications of all persons applying to be registered under the Act.
5. That the law should be so framed that the simple act of prescribing medically, or surgically, by any unqualified person, for gain, shall be considered an infringement of the statute, as being evidence of the assumption, on the part of the prescriber, of a medical status, position, or title.
6. That upon any unqualified person having been found to have so prescribed, or pretended to be qualified, the onus of proving his title to prescribe or practise shall be put upon him—as every registered practitioner is supplied with a certificate of his registration by the registrar.
7. That the production of the registrar's certificate shall be deemed sufficient evidence of the medical practitioner who holds it being duly registered.
8. That there shall be greater facility for prosecuting and punishing offenders against the provisions of the “Medical Act” than at present exist.
9. That in addition to the general register for the kingdom, there shall be published a separate register for each portion of the United Kingdom, at a cheap rate, so as to be procurable by every person desirous of having a copy.
10. That the 23d clause should be struck out of the “Medical Act” as it countenances quackery in its worst forms, for it seems anomalous that an Act which appears to be intended, and was ostensibly framed to protect the regularly qualified practitioner, should be made either openly or covertly

to foster the lying systems of homeopathy, hydro-pathy, and the like.

The committee have, in several instances, written to practitioners who were not complying with the law, and have induced them to become duly registered.

Recently the committee have received communications from country members complaining of persons in their locality assuming certain medical titles without any right to do so. They now suggest that a circular should be sent to every person so complained of, that he may send to the committee a statement of his exact qualifications, if he possess any.

The committee have received a copy of the Poor Relief Amendment Bill, now before Parliament. They regret that it does not contain several of the provisions for which the association have petitioned, and is, on the whole, not so comprehensive as they hoped it would be. From communications they have received from the President and Secretary of the Irish Medical Association, they are led to believe, however, that the Chief Secretary will make several important amendments in the Bill before it shall become law.

The committee have recently summoned some unqualified persons, practising in Belfast, to the Petty Sessions Court. The case is still pending, as it has been postponed on a point of law. The committee, however, have no doubt of obtaining convictions against the persons in question, and they are determined to enforce the law against all unqualified persons practising medicine, so far as they have the power. The committee having learned by experience that some change relative to the county members of committee should be made, beg leave to suggest that these gentlemen—three for each county in Ulster—should be styled corresponding members of committee, and that they should be summoned to attend at quarterly meetings only. This plan would save your secretary a considerable amount of labour, and the association some expense.

In conclusion, the committee have to report that the association is in a flourishing condition. It now numbers one hundred and fifty-six members, and several gentlemen have signified their intention of joining our ranks. The committee believe that such a course is the solemn duty of every registered practitioner in Ulster who values the rights which belong to our profession. Some there are, no doubt, who will not perceive any good in an association which does not promote their individual interests. Men having such feelings had better not join us. They cannot appreciate the moral power of an intelligent body of men associated for the purpose, not of protecting themselves alone, and the rights of their class, but also for promoting, by their united influence, the best interests of the community at large.'

Surgeon Browne stated that, during the time the association had been in existence, a great deal more

had been done than was stated in the report. They had either got parties to register, or put parties who had been placed in a false position into a proper position. They had also been the means of amalgamating the North with the South of Ireland. There was no doubt that many parties had been disappointed at their not having done more, and many would blame the committee for not having taken up more stringently prosecutions against those who might be considered unqualified practitioners; but it was better, in all those cases, to induce the parties to leave off practice, particularly through the medium of the public press, if possible.

He wished the public to understand that the motive which actuated the association throughout was not to protect themselves at all against unqualified practitioners, because there was not an individual entered upon the registry who had not an opportunity of protecting himself by appealing to the public at large, and stating that he was a registered man. But the public at large would not take the trouble of making that inquiry, and, therefore, it became the duty of that association to come forward for the benefit of the public, and expose parties practising illegally. He believed, if the society would be only worked as actively during the coming year as it had been for the last eight months, they would have a still greater accession of good for the next year, by their acts, and with the assistance and co-operation of other associations. After referring to the valuable assistance which the association had received from Dr. Mackessy, President of the Irish Medical Association, Surgeon Browne concluded by moving the adoption of the report.

Dr. Corby seconded the motion.

Dr. Michael Magee then addressed the meeting at some length on the objects and duties of the association, and expressed himself dissatisfied with the committee for not having prosecuted a larger number of quacks or unlicensed practitioners. They had formed, he said, what was now called the Ulster Medical Association, for the purpose of carrying out the provisions of the Medical Registration Act—an Act that seemed to please few and dissatisfy all, but which, nevertheless, had this much good in it, that it had separated the wheat from the chaff, and had drawn a conspicuous line of demarcation between honest men and knaves. He was sorry to think that the committee had not given sufficient of their time and attention to the exposure of those hydra-headed monsters that had been living so long and so sumptuously, too, on their profession; and he concluded by expressing a hope that during the next year the committee would leave nothing undone to bring up every unqualified practitioner, if not for conviction, at least for exposure, and expel such pretenders from amongst them.

Surgeon Browne, in the course of some observations, said the association had attended to the general interests of the profession, and to every matter in which the community was concerned. He contended that they had done in the limited period of eight months as much good as possibly could be done by people in their position. With regard to the matters complained of, he might state that they wanted the necessary authority. They were now seeking for that authority and power, and when they would get those powers he would assure Dr. Magee and the public that they would be put into active operation.

After some remarks of a similar nature from the Chairman, the report was unanimously adopted.

Dr. Patterson (Treasurer) read a statement of the accounts, from which it appeared that since the formation of the society the income had been £35 1s 10d; the outlay was £27 2s, and there was at present a balance of £7 19s 10d in hands.

Moved by Dr. Browne, seconded by Dr. Corry, and Resolved—

“That the Report just read, together with the Treasurer’s Statement of Accounts, be now received, adopted, and entered upon the minutes.”

A Ballot having then been taken for a Chairman, and the members of Committee going out by rotation,

Dr. M’Gee, J.P., was unanimously re-elected Chairman for the ensuing year, and the following gentlemen were declared the Committee for the same period, viz:—Dr. Murney, J.P.; Surgeon Johnston. Dr. Black. Dr. Cuming. Professor Ferguson, Dr. Stewart, Dr. Heeney, Dr. Dickson. Richard Pring, Esq.; Dr. Halliday, Surgeon Warwick, and Dr. Murray, of Ballymacarett.

The following were also declared the “County Corresponding Members”:

Antrim.—Dr. O’Connor, Ballycastle; Dr. Kidd, Ballymena; Dr. M’Kee, Randalstown.

Derry.—Dr. Babington, Londonderry; Dr. Cavin, Coleraine; Dr. Graves, Cookstown.

Down.—Dr. Filson, Portaferry; Dr. Jamison, Newtownards, Dr. May, Rathfriland.

Cavan.—Dr. Taylor, Bailieborough; Dr. McGaghan, Kingscourt.

Armagh.—Dr. M’Kinstry, Armagh; Dr. MacLaughlin, Lurgan; Dr. Davis, Newry.

Donegal.—Dr. Thorpe, Letterkenny; Dr. Eames, Dunfanaghy; Dr. Bagot, Malin.

Monaghan.—Dr. Fleming, Carrickmacross; Dr. Young, Ballybay; Dr. Donaldson, Clontibret.

Tyrone.—Dr. Scott, J.P., Aughnacloy; Dr. Neville, Dunganon; Dr. Fleming, Omagh.

Fermanagh.—Dr. Maxwell, Derrylin; Surgeon Robert Hayes, Lisbellaw.

Moved by Dr. Halliday, seconded by Dr. Mulholland, and resolved—

“That the grateful thanks of the Association be given to Dr. Patterson for his valuable services, and that he be requested to continue Treasurer.”

Moved by Dr. Michael M’Gee, seconded by Surgeon Gribben, and resolved—

“That the warm thanks of this meeting be given to Dr. Browne for his labours on behalf of this Association, and that he be requested to act as Honorary Secretary for the ensuing year.”

William M’Gee, M.D., Chairman.

Dr. Michael M’Gee having been called to the Chair,

It was moved by Dr. Stewart, seconded by Surgeon Warwick, and carried by acclamation—

“That the best thanks of this meeting be given to Dr. M’Gee, J.P., for his kindness in presiding, and for the many instances in which he has shown his sincere devotion to the honor and interests of the Medical Profession.”

It was then unanimously agreed that a deputation from the association be appointed to attend the meeting of the profession in Dublin on the 4th June next.

The Treasurer then announced that the annual subscription is now due.

The meeting then separated.

Michael M’Gee, M.D., Chairman.

Sam. Browne. Lic. K. and Q. Coll. Phy., &c.,
Honorary Secretary.

At the committee meeting preceding the general meeting the following gentlemen, belonging to the Newry Chirurgical Society, were ballotted for and elected, viz:—Dr. J. Colvan, Dr. J. Morrison, Dr. A. Erskine, Dr. William Starkey, Dr. Joseph Robinson, Dr. Robt. Johnstone, Dr. W. K. Nesbitt, Dr. Joseph May, Dr. Joseph Crawford, Dr. W. A. Davis, Surgeons Thomas Black, Charles Anderson, Thomas Mulligan, James M. M’Conville, Andrew M’Bride, and Arthur M’Court.

Dr. S. T. Haslett, of Laghey, and Dr. Wilberforce Arnold, of Belfast, were also elected members.

COURT PROCEEDINGS

Belfast Weekly News 12 May 1860

Tuesday 8th May 1860

UNLICENSED MEDICAL PRACTITIONERS

Mr. Edward J. Carew of Academy Street; Mr. Robert Johnston of Durham Street; and a Mr. McCloy, were summoned by Surgeon Browne, at the instance of the Ulster Medical Protective Association, “for having on the 3rd May inst. at Belfast, wilfully and falsely pretended to be practitioners in medicine and physicians and that they did supply and prescribe medicine contrary to the 21st and 22nd Vic., cap. 90.”

Ulster Medical Protective Association

1860–1861

Chairman William M'Gee

Mr. Seeds appeared for the prosecution; Mr. Rea appeared on behalf of Mr. Carew; Mr. McLean for Mr. Johnston, and Mr. O'Rourke for Mr. McCloy.

Surgeon Browne, Secretary, and Dr. Patterson, Treasurer, of the Ulster Medical Protective Association, attended to watch proceedings on behalf of that body.

After some conversation between the Bench and the legal gentlemen engaged on both sides, the Bench decided on postponing the case until the 5th of June next, the costs to await the decision of that day.

COMMITTEE MEETING

Belfast News-Letter 18 May 1860

The first meeting of the newly-appointed committee of the Ulster Medical Protective Association was held yesterday, at the Belfast General Hospital, Dr. Stewart in the chair. Present—Drs. Patterson, Murray, Johnston, Warwick, Browne, Dickson, and Mr. Pring. After the confirmation of the minutes of last meeting, it was resolved that the committee shall meet the second Thursday in each month, at three o'clock, P.M., and that the quarterly meetings, to which the "County Corresponding Members" shall be summoned, shall be held on the second Thursdays of August, November, February, and May, either at three o'clock, or noon, as may be found most expedient. It was also resolved that the form of circular read by the Secretary should be adopted, and that a copy of it should be sent to every one against whom a complaint shall be lodged for assuming a medical or surgical title, or for practising without a legal right or qualification to do so. The following is the circular:—

"I am directed by the Committee of the Ulster Medical Protective Association to acquaint you of a complaint which has been made to them, that you assume a professional title and practice medicine and surgery without any legal right to do so, and as your name does not appear in the Medical Register, I have to request that you will forward a statement of your professional qualifications to me, that I may submit the same to the committee. I have also to inform you that, if you do not comply with this request, and continue to practice illegally, the Ulster Medical Protective Association will take such steps in your case as our counsel may advise."

As the Ulster Medical Protective Association feel very anxious to keep up the most friendly relations with the Irish Medical and the other Branch Associations, the committee appointed the Chairman and Secretary, along with Dr. Murray, of Ballymacarrett, a deputation to proceed to Dublin to attend the annual meeting of the Medical Association of Ireland on the

4th of June, and to represent the Ulster Society. It was also resolved to recommend to the members of the Ulster Medical Protective Association that they should use all their influence with the Fellows of the College of Surgeons of Ireland to record their votes in favor of Dr. Mackesy in the vice-chair of the College, as the committee believe that Dr. Mackesy is justly entitled to this mark of respect from his brethren of Ireland for his unwearied exertions in maintaining the honor, respectability, and the best interests of the profession, while they also believe that a more judicious selection could not be made for the important appointment in question. The committee, therefore, trust that every Fellow of this College of Surgeons in Ireland in connexion with this association will vote for Dr. Mackesy, of Waterford, the able, tried, and zealous friend of the medical profession.

COURT PROCEEDINGS

Belfast News-Letter 7 June 1860

NEWS COLUMN

Yesterday, a case of very great importance to the public was brought before the Police Court, at the suit of the Ulster Medical Protective Association, in the name of their honorary secretary, Surgeon Browne. The object of the prosecution was to endeavour to put down the system, too prevalent, of individuals practising as medical men while in no wise qualified for the duties of such an important profession. This class of practitioners, too, very generally placard the walls of our town and its vicinity, as well as neighbouring towns, with indecent bills; and, with the object in view of putting a stop to such, and of protecting the public from quackery, the association took proceedings against certain parties in Belfast, and a report of the trial will be found in our police report in another column [below]. The law has for the present been vindicated; and, as the case heard was the first brought into court, it may prove a warning to others, and be sufficient to deter them from setting themselves forth as "duly qualified medical practitioners" until they first duly register their names in the proper quarter, and so give the public a guarantee that they do not belong to the class generally designated by the term "quacks." The Ulster Medical Protective Association deserves the thanks of the community for having taken up this matter; for, while preserving their own interests they are doing that which will prove equally beneficial to the general public.

LEGAL COLUMN

Edward J. Carew, of Academy Street; Robt. Johnston, of Durham Street; and Michael M'Cloy, Divis Street, were summoned by Surgeon Browne, at the instance of the Ulster Medical Protective Association, "for hav-

ing, on the 3rd May last, at Belfast, wilfully and falsely pretended to be practitioners in medicine and physicians, and that they did supply, and prescribe and supply, medicine contrary to the 21st and 22nd Vic., cap. 90.”

The case had been postponed from a previous day, and came on for hearing.

Mr. J. M. Thompson (barrister), with Mr. Seeds, appeared for the prosecution, and Mr. M'Lean for the defence.

Surgeon Browne, Secretary, and Dr. Patterson, Treasurer of the Ulster Medical Protective Association, attended to watch the proceedings on behalf of that body.

The case of Mr. Carew was the first called on.

Mr. M'Lean stated that his client had been informed that there would be no further proceedings taken in the case, and that Mr. Rea, who had been engaged for Mr. Carew, was now out of town,

Mr. Seeds said it was arranged on Tuesday that the case should be heard that morning.

Mr. Lyons—You are aware, Mr. Thompson, that this is an adjourned summons. The last day it was here the counsel or attorney for the prosecution could not satisfy the Bench that Dr. Browne had a *locus standi* in this court. It is for you now to satisfy us that that preliminary objection was not a right one.

Mr. Thompson said it was a very proper suggestion, and an important matter of inquiry. Counsel then cited several law authorities to show that any party might be the complainant in a criminal offence, unless in cases where the statute particularised who was to bring the complaint.

Mr. M'Lean said if there had been an information sworn in the case he would wish to see it. He believed no information had been made, although it was absolutely necessary such a thing should have been done. He received no instruction in the case at all, and was only acting for Mr. Rea. Surgeon Browne, he believed, could not make a sworn information. He knew of no complaint, and had no complaint to make.

Mr. Thompson said the rule of the law was that they might proceed without any information. If any offence was committed against the statute law, the magistrates were bound to inquire into it.

Mr. Lyons said the Act under which they were proceeding was the lamest he had ever seen; and he thought, for the safety of the Bench, that there should be informations in the case.

Mr. Thompson then drafted an information, embodying the charges against the defendant set forth in the summons.

Mr. M'Lean objected to the information on the ground that it was bad in substance, as it did not set forth a distinct charge against the defendant.

The Bench overruled the objection, and allowed the case to be proceeded with.

Mr. Thompson then stated the case for the prosecution, detailing the charges brought against the defendants, and remarking upon the seriousness of the offences as affecting not only the profession as a body, but the community at large. He also explained the nature of the Act of Parliament under which the prosecution had been brought, and contended that the defendant, by not being entered on the Medical Registry, violated the provisions of that Act.

Constable Cairns, examined by Mr. Thompson—On the 3rd May last, I went to the residence of the defendant, 17, Academy Street. I had previously seen bills of his on walls through the town. When I went into the shop I asked a woman could I see the doctor. She went up-stairs and sent the defendant down to me. On seeing him, I asked if he were the doctor? and he said he was. I told him I had got a very severe cough and a pain in the chest, He opened a door, and told me to go into a little room where there was a lot of empty bottles. He then told me to loose my breast, and he made one of those telescopes (stethoscopes) with an old account-book (Laughter.) He put it to my chest and applied his ear to it. (Renewed laughter.) After talking a lot of “bladders and nonsense” about having got £5 for curing parties in Newtownards, and £100 from the late Marquis of Waterford for medical treatment, he told me I was like a big tree that had grown up without any substance in me. (Great laughter.) I told him I had been with Dr. Corry, and he said—“Corry is no doctor at all”—(laughter)—and that he (Carew) had just got three of his patients that week, for whom Dr. Corry could do nothing, but who were now getting on well under his treatment. He also stated that before he dirtied paper with ink his charge was £5 to a gentleman. I told him I was no gentleman, and he replied that his lowest charge was £1 to a man like me. (Laughter.) I told him I had not so much as £1. I gave him 10s., and he took credit for the other 10s., which I was to pay him when he would cure me. He said he could not make that bargain with me, but that the sooner I would give him the other ten shillings the better it would be for myself. (Laughter.) I was then to give him 5s. the following Saturday, and the other 5s. in the week after. He said there was no mistake but that he would cure me once he took it on hands. He said I wanted “new machinery”—(laughter)—and observed “that there were as many diseases following a man as there were hairs on his head, and that it took a smart man like him to know six of them at a time.” He further stated that there had been three of the foremost doctors in Belfast with him that day getting information from him about curing their patients—(laughter)—and that he would give them none, because they understood nothing about his mode of curing, He gave me a little pill about the size of a pickle of hempseed, and a spoonful of liquid, which I took. I told him I was a stranger in town, and

that I had seen his bills on the corner. I asked him if he had any in the house. He said he had, and gave me one. He gave me this handbill. (This bill informed the public of the efficacy of Mr. Carew's cures; that his consulting department was conducted by "a regularly qualified medical practitioner;" and also, that he charged according to the nature of the case, and the means of the party.) The defendant told me that he gave a man £10 a-year for posting up those bills, I asked him would the medicine do me any good that night, and he said that I must go to him for three days running, and "every other day" until I was cured. I told him I wished a receipt for the 10s. lest my mother might think I had gone on the spree. (Laughter.) He then gave the following:—"I have this day received 10s. from Mr. Thos. Cairns for a cure of a chest affection.—3rd May, 1860. E. J. Carew." He told me he was the doctor when I went into the shop.

Cross-examined by Mr. M'Lean—When I said I was from the country, and a stranger in Belfast, it was a lie. When I said I got the 10s. from my mother it was a lie. It was Inspector M'llroy sent me to Mr. Carew's establishment. He did not tell me to tell the lies. He told me not to let Mr. Carew know that I was a constable. Inspector M'llroy gave me the 10s. I did not know who got M'llroy to act in the case. I was bound to obey him.

Surgeon Browne, examined by Mr. Thompson—I am Honorary Secretary to the Ulster Medical Protective Association. In that capacity I allowed my name to be used in this case, and by directions of the committee. The President of the Association is Dr. M'Gee, J.P., and the Treasurer Dr. Patterson. Professor Ferguson and others are in the council.

Mr. Thompson—I now tender the Medical Registry as evidence. According to the Act of Parliament it was evidence in the case, and the defendant is bound to show that his name is in it or ought to be in it.

Mr. Lyons—Prove it before you tender it as evidence.

Mr. Thompson said they did not require to prove it; the words of the Act were—"Purporting to be a copy." What he handed in purported to be a printed copy, published by authority.

Mr. M'Lean contended that it was necessary to prove it as in the case of any document coming out of the hands of the officer of a court. The Secretary to the Medical Association in Dublin held the original list, and a copy of that should be signed by him, and it would then be very necessary, under the Act, for some one in Belfast to prove the handwriting.

Mr. Dunville thought the words "purporting to be a copy" set the matter at rest.

Mr. Lyons said they would receive it as evidence.

Mr. M'Lean said his next point was that, according to law, any information should set forth the time and place, when and where, the alleged offence was com-

mitted. The information of Surgeon Browne only set forth the time and the residence of Mr. Carew, but did not say where the offence had been committed. He, therefore, called on the Bench to dismiss the case.

Mr. Lyons said that would have been a good point if made before the evidence had been given; but the evidence made up for the want in the information.

Mr. M'Lean would have raised the point earlier, but he could not read the information, and had only just received a copy of it.

Mr. Lyons said they ruled against Mr. M'Lean on that also.

Mr. M'Lean said he then came to his defence. He had only to hand in a certificate or diploma from the Apothecaries' Hall, Dublin, in order to show that the defendant was properly qualified; and he would examine medical gentlemen in court to prove that it was a proper certificate or diploma.

Surgeon Browne, examined by Mr. M'Lean—I could not tell is this (document handed witness) a certificate of the Apothecaries' Hall, Dublin.

Dr. Patterson, examined by Mr. M'Lean—I could not say that it is a certificate of the Apothecaries' Hall, Dublin. Perhaps Professor Ferguson could.

Professor Ferguson, examined by Mr. M'Lean—My opinion is that this is a diploma of the Apothecaries' Hall, Dublin, It is in the name of "Edward J. Carrooe."

Mr. Lyons—What date?

Witness—It is dated 1834.

Mr. Lyons—There has been no evidence given yet as to the man's name.

Mr. M'Lean—I intended to raise that point, but I will now prove that the defendant is the gentleman named in this diploma.

Surgeon Browne, examined by Mr. M'Lean—He had corresponded with the secretary of the Apothecaries' Hall, Dublin, in relation to this matter, and received a letter saying that 'Edward J. Carew' was the same individual who had received a diploma from that hall in 1834 as "Edward J. Carrooe."

Mr. M'Lean said they had the opinion of a late Attorney-General that any gentleman holding a diploma from the Apothecaries' Hall, Dublin, could practise in medicine in any part of her Majesty's dominions.

Mr. Lyons—But show us that Mr. Carew is registered under the Act.

Mr. M'Lean contended that it was not compulsory on any gentleman to register; but he could not recover fees in a civil court unless he had registered.

Mr. Lyons held that the defendant, having set himself forth in the printed bill which he gave Cairns as "a duly qualified practitioner," was bound to register, or to suffer the penalty if he practised.

After some discussion as to this legal point, the defendant said he would register properly under the Act.

Surgeon Browne said that was all they wanted.

The Bench then postponed judgment for one month, in order to allow the defendant to register

S. BROWNE *v.* M'CLOY.

Mr. Seeds said the defendant had left the town, and they would withdraw the case.

S. BROWNE *v.* JOHNSTON.

Mr. Thompson said, inasmuch as the law had been vindicated, they would withdraw this case also.

Mr. Seeds—Or let it be dismissed.

Mr. Carew said it was a hard thing that they should prosecute a man who had a diploma and let others off. He also wished to know if he would not be allowed his costs?

Mr. Lyons said the Bench had postponed the case for a month, and if, in the meantime, the defendant did not register himself, they would give the complainant full costs.

PRESENTATION OF PETITION
Belfast News-Letter 15 June 1860

REGISTRATION OF BIRTHS &c.

On Tuesday [12 June 1860], in the House of Commons, a petition was presented by Sir. H. Cairns, from the Ulster Medical Protective Association, in favor of the Government Birth, &c., Registration (Ireland) Bill, and praying for some alterations.

EXECUTIVE COMMITTEE
Belfast News-Letter 10 August 1860

Yesterday [9 August 1860], a quarterly meeting of the Executive Committee of this association was held in the library at the General Hospital—Dr. Dickson in the chair.

Surgeon Browne, Hon. Secretary, read the minutes of last meeting, which were approved. He went on to observe that both the Registration Bills, which had been before the House of Commons, had been withdrawn. In some measure he was sorry for that, as he thought Mr. Cardwell's might, if it had been passed with certain amendments, have been of great advantage to the public, and in a less degree of the profession. There was a strong probability that a Bill would be introduced next session, and it was their duty to make every exertion with the view of having another measure brought forward. Another Bill in which they had considerable interest—namely, the one for the amendment of the Poor-law—had been entirely changed, and was now simply a continuance Bill to keep the Commissioners in office for two years from September next, when their powers would otherwise

have ceased. It was probable that another Bill would be introduced, and they should be very vigilant as to any clauses introduced which might materially affect the profession.

The Chairman—Is there any necessity for appointing a committee to watch over it?

Surgeon Browne said that the Council, which met every month, would attend to it. He then suggested that the Ulster Society should become connected with the Irish Medical Association, either by payment of a sum of money, or in some other way.

A long conversation ensued as to the rules of the Irish Medical Society, and the feeling of the committee was that, while maintaining their own provincial organisation, they should co-operate with that society in every possible way. Ultimately, on the motion of Dr. Murney, the Secretary was instructed to write to the Irish Medical Association to state that it was the wish of the Ulster Medical Protective Association to co-operate in all matters for the benefit of the profession, and to inquire in what way, in their opinion, they could join in advancing their common object, and also what subscription would constitute members of the Ulster Medical Protective Association members of the Irish Medical Protective Association,

Dr. Patterson, the Treasurer, said that the dispensary medical officers were not supporting the association as they should do.

Surgeon Browne said that they were more called upon to join it than any others. He did not believe the medical officers of dispensaries were under dread of the Poor-law Commissioners, and, from what he had himself heard and seen, he did not believe the Commissioners were at all enemies to the profession. Indeed, on one or two points, his mind was completely changed after the explanations he had heard made.

A letter was read from Dr. Thomas Babington, of Derry, withdrawing his name from the committee and from the association, in consequence of the course taken by the members at the previous meeting in reference to the Poor-law Amendment Bill.

Dr. Patterson said that Dr. Babington was a county infirmary man, and it could hardly be expected that he would remain a member, when the association had not supported the claims of the Infirmary doctors.

Surgeon Browne—I think they took a very wrong view of the clauses they referred to.

The Chairman—It strikes me that they were very favorable to them.

Dr. William Browne was unanimously elected a member of committee, in the room of Dr. Babington.

Dr. Patterson reported that 96 new members had been admitted during the year.

Surgeon M'Gowan, of Trillick, and Dr. Shannon, of Poyntzpass, were balloted for and elected members.

The remaining business was routine.

Ulster Medical Protective Association

1860–1861

Chairman William M'Gee

COMMITTEE MEETING

Northern Whig, Belfast 12 October 1860

The committee of this association met yesterday [11 November 1860], at the General Hospital, Dr. Stewart in the chair.

After the transaction of the ordinary business, Dr. Browne, the Honorary Secretary, brought under the notice of the committee the names of several persons reported as illegally practising medicine, to whom he had sent the approved cautionary notice. From some of these persons he had received satisfactory replies, but in other instances the statements were evasive.

After some discussion, it was resolved to bring these cases under the notice of the next quarterly meeting, in November, that such steps might be taken regarding unqualified practitioners as likely to put a stop to their illegal and dangerous proceedings.

The Secretary likewise read letters from Dr. Quinan, the Secretary of the Irish Medical Association, and from Dr. Mackesy, of Waterford, relative to the commission which is likely to be appointed to enquire into the working of the Irish Poor Law.

The meeting expressed the ardent desire of the Ulster Protective Association to co-operate with the other medical societies in procuring for the country and for the profession a better administration of the law than there is at present; and the secretary was directed to convey to Drs. Quinan and Mackesy the views of the committee on this very important subject.

The chairman then directed attention to a case reported in the local papers recently, relative to a "medical man" having been brought before the magistrates and fined for a trespass, etc., on the County Down Railway. On investigation, however, by the Ulster Protective Association, it was found that the individual in question is not connected with the Medical Profession, as his name does not appear either on the Medical Register or on any authorised professional list.

The committee thanked Dr. Stewart for noticing the case, as they felt the profession had no right to have the person referred to ranked among them.

QUARTERLY MEETING

Belfast Weekly News 17 November 1860

Thursday [15 November 1860], the quarterly meeting of the committee of the above association was held in the library of the General Hospital, at eleven o'clock—Dr. Patterson in the chair. Amongst those present, besides the Chairman, were Surgeon Browne, Dr. Brown (Derry), Dr. Stewart, Dr. Cumming, Dr. Murray, Dr. Johnston, and Dr. Black.

PERIPATETIC PHYSICIANS

Belfast Newsletter 8 January 1861

Peripatetic Physicians—A couple of this class of practitioners have been indefatigably engaged in distributing, throughout those localities of Belfast chiefly inhabited by the working classes of higher and lower grades, their own bills, in which they profess to cure almost every malady—from toothache to hydrophobia. With one disease, always too prevalent, they evidently do not wish to deal in a curative sense—namely, public gullibility. These travelling doctors, in their bills, display intense contempt for grammar, the orthography being, perhaps, an index to the purity of their medicines. Their mode of beating up patients is expert, if not exactly professional. They chalk every door where a bill is delivered, and when the document is called for some hours afterwards, special inquiry is made after the health of the family; and, if no one stands in need of their nostrums, a hope is expressed that so healthy a state of matters may not long continue. There exists in Belfast a Medical Protective Association, with active officers. We commend these peripatetic Galens to their particular attention.

COMMITTEE MEETING

Belfast Daily Mercury 25 January 1861

The monthly meeting of the committee of this society was held yesterday [24 January 1861], at 12 o'clock, in the Belfast General Hospital, when, after the transaction of the ordinary business, it was resolved that a report, based upon the replies received from the medical officers of workhouses and dispensaries in Ulster, in answer to queries recently submitted to them, should be drawn up and submitted to a general meeting of the profession, to be called by public advertisement in the newspapers, and by circular to the members of the committee. It was also resolved that meetings shall be held on the 31st inst., at noon, in the Belfast General Hospital, and that questions relative to the amendments required in the Poor Law, Medical Charities, and Vaccination Acts, should then be brought under discussion. A resolution was likewise adopted directing the secretary to advertise the intended meeting in the *Northern Whig*, *Belfast News-Letter*, and *Daily Mercury*, and also in the *Newry Telegraph* and *Londonderry Sentinel*. The chairman, treasurer, and secretary, having been requested to prepare the report for the general meeting, the committee adjourned.

SPECIAL MEETING

Dublin Medical Press 13 February 1861

AT the annual [sic] meeting of the members of this Association, held in the Library of the General Hospital, Dr. McGee, J.P., in the chair. The other members present were, Dr. Patterson, Dr. Stewart, Dr. Browne, Dr. W. Scott, J.P., Aughnacloy; Dr. Stronge, Dr. Murray, Ballymacarrett; Dr. Scott, Depot Battalion; Dr. M. McGee, Dr. Warwick, and Dr. Arnold.

Dr. Browne, hon. secretary, read the minutes of the previous meeting of committee, after which he stated that he had received letters of apology from Dr. W. Browne, Londonderry; Dr. O'Connor, Ballycastle; and Dr. Davis, Newry.

Dr. Stewart mentioned that he had received a letter from Dr. Filson of Portaferry, apologising for his absence from the meeting.

Dr. Browne then read the following

REPORT OF SUB-COMMITTEE.

“As directed by the Association, at their quarterly meeting held on the 15th of November last, your secretary sent copies of the queries which had been agreed on to the several medical officers connected with workhouses and dispensaries in Ulster. The replies received, and which have been carefully examined by the sub-committee appointed, are in many cases very important, some of the suggestions being exceedingly valuable. Arising out of them, your sub-committee now submit the following suggestions, for the consideration of this meeting:—

“First.—That petitions to both Houses of Parliament should be prepared, copies thereof being sent to the Poor-law Commissioners, praying for the introduction of a Bill for the Registration of Births, Deaths, and Marriages in Ireland, the medical officers of dispensaries being the Registrars under the Act, with suitable remuneration. That vaccination be rendered compulsory, and that each successful case shall be paid for. That a simple and more effectual method of issuing tickets to the sick poor, for medical relief, shall be provided, the form of the ticket stating that the grantor has made himself acquainted with the circumstances of the applicant, it being understood that domestic servants can only obtain such relief at the expense of their masters. That the grantor of a relief ticket shall be able to cancel the same, and that the medical inspector shall have the same power, in any cases submitted for his decision. That, subject to the approval of the guardians, the cost of medicine and attendance in cases of cancelled tickets be paid for by the recipient, or, in default, by the grantor of the relief ticket. That, for the sake of the sick poor and the public, medical officers of dispensaries shall be ex-officio “wardens” for contagious diseases. That no spirit dealers or hucksters be eligible to serve as wardens. That the salaries of the medical officers shall be fixed by the Poor-law Commissioners, and not by the

guardians. That suitable allowance should be made for keep of horse and car-hire. That the amount of writing demanded of the medical officers of dispensaries may, and should be, greatly lessened. To carry out the preceding provisions for the benefit of the sick poor, medical inspectors should not only be continued, but increased in number. These suggestions are in reference to the Medical Charities and Vaccination Acts alone.”

POOR-LAW ACTS

The following are the suggestions, arising out of the replies received, which your sub-committee submit to the meeting relative to amendments in the Poor-law Acts:—“That suitable hospital accommodation, compatible with the wants of the district, should be attached to each union workhouse. That individual members of families should be admitted to hospital relief on medical certificate, without the head of the family being compelled to enter the workhouse. That persons dying in the receipt of poor-law relief may be buried in workhouse grounds at the cost of the rates, on receipt of medical certificate, under the superintendence of the relieving officer. The sub-committee have now only to recommend these suggestions to the notice of the meeting, that the Association, if it see fit, may found resolutions and petitions thereon.”

By order of the Sub-Committee,

SAM. Browne, Hon. Sec.

On the motion of Dr. Patterson, seconded by Dr. Murray, the report was adopted.

Dr. Browne said that their medical brethren would perceive that the Association was earnestly working for their benefit, and he trusted that they would feel the necessity of cordially coöperating with the Association, and supplying the necessary funds to enable the committee to carry out the objects in view. In fact, it was absolutely necessary that their medical brethren should do so. They must know that, in order to send gentlemen to London to look after the rights and interests of the profession when any bill affecting them was before the House of Commons, their medical friends in Ulster would be required to give a helping hand by subscribing liberally to the funds of the Association. Already he was glad to be in a position to state that, from the answers to the queries sent out by the committee, their friends at a distance had promised to contribute; and some of them had gone the length of suggesting that the committee should strike a rate upon them, but the Association had no power to do so. Their medical brethren should bear in mind that it would be themselves that would be benefited by the labours of the Association, and not any of the gentlemen who were upon the committee, who were totally unconnected with dispensaries or workhouse establishments. In reality, he might say that the committee were working more for the public good than for the medical profession; for there was not one

of their objects, if carried out, that would not benefit the sick poor. He hoped there would be no ground for again saying of their medical friends what had already been said by the clever editor of the DUBLIN MEDICAL PRESS—namely, that they were influenced either by cowardice or parsimony in not coöperating for the general good. He believed the time was come to be vigilant and active, and if a decided movement were not made to sustain the interests and the rights of the profession, it, would not be the fault of the committee of the Association.

Dr. M. McGee expressed a hope that medical officers in workhouses and dispensary establishments throughout the country would feel it their duty and their interest to come forward and assist the Association, for he was bound to say that they had not hitherto coöperated with the Association in the manner it had been expected of them. For every shilling subscribed by the members of the Association in Belfast to the funds, the medical officers to whom he had alluded should at least subscribe ten shillings.

Dr. Stronge mentioned as a fact that many dispensary officers were afraid to come forward lest they might be pointed at, or suffer perhaps for their forwardness.

Dr. Stewart said that the principal issue involved in the case was an important one, and he hoped that dispensary practitioners would feel it their interest to come forward and assist the Association. They could not invest their money better than by subscribing liberally to its funds. It was their particular interest to do so, for the medical gentlemen who were working for them on the committee were totally unconnected with dispensary establishments, and had no object in view but to promote the public good and uphold the rights and the dignity of the profession.

It appeared to be the unanimous feeling of the meeting that all medical practitioners connected with workhouses and dispensaries should subscribe at least £1 to the funds of the Association.

The following resolutions were unanimously adopted:—

Moved by Dr. Patterson, seconded by Dr. Murray, and resolved—“That the report of the sub-committee be received and entered on the minutes.”

Moved by Dr. Scott, seconded by Dr. Stewart, and resolved—“That this meeting, approving of petitions to Parliament on the subjects of a Bill for the Registration of Births, Deaths, and Marriages in Ireland; and also for one founded on the preceding, to render vaccination compulsory in all cases, recommend to the Executive Committee of the Ulster Medical Protective Association to have such petitions prepared and presented to both Houses at the proper time.”

Moved by Dr. Murney, seconded by Dr. Michael McGee, and resolved—“That petitions to both Houses of Parliament, embodying the principles of the sug-

gestions contained in the report of the sub-committee just read, relative to all the amendments required in the Poor-law and Medical Charities Acts, be prepared and presented, in the name of this Association, at the most suitable period of the ensuing session.”

Moved by Dr. Warwick, seconded by Dr. Arnold, and resolved—“That, should a committee of the Commons be appointed to inquire into the working of the several poor-law acts, the Executive Committee shall select such members of this Association as they may deem best calculated to sustain the claims of our professional brethren who are officially connected with these Acts.”

Moved by Dr. Stronge, seconded by Dr. Browne, and resolved—“That a fund be raised for the purpose of defraying parliamentary and other expenses, and that the medical officers attached to workhouses and dispensaries in Ulster, and other members of the profession, be requested to subscribe to this fund.”

Moved by Dr. Patterson, seconded by Dr. Stewart, and resolved—“That copies of the Sub-Committee's Report, the resolutions of this day, and of the petitions, when prepared, be sent to the Poor-law Commissioners, and that every legitimate means be used to urge on the Commissioners the adoption of the views of this meeting.”

EDITORIAL

Belfast Daily Mercury 1 February 1861

We have in Belfast a Society that is called the “Ulster Medical Protective Association.” Such a body, we admit, is greatly needed, and if it only discharged its duties independently and fearlessly, it would confer vast benefits on the Profession, and also on the public.

But we observe that while every exertion is made to serve the Profession, no attention whatever appears to be bestowed on the interests of the public. In the report of the Sub-Committee, which we publish, it will be seen that the primary consideration is the Medical Profession. We do not intend to bore our readers by going through the recommendations of the Committee seriatim, but they may judge of the fact that the “Protective Association” is not unmindful of its own interests when it demands for Dispensary Doctors “keep of a horse and car-hire!”

It is far from our intention to be understood as opposed to an amelioration of the Dispensary Doctor's position in Country Districts. On the contrary, we consider that under the new law they are inadequately paid, and exposed to great hard-ships. In fact, the new law is an absolute failure, and does not work anything like so well for the poor as the old Dispensary system.

But what we object to is, that this Association appears to think the poor were made for its profit—

that there is no interest to be consulted but the Medical. We could point to many cases not unworthy of the Association's attention, assuming that in their "Protective" character they desire to maintain the honour and dignity of the Profession.

BELFAST BOARD OF GUARDIANS

Belfast News-Letter 20 February 1861

Yesterday [19 February 1861], the usual weekly meeting of this body was held in the Board-room of the Workhouse—Dr. M'Gee, J.P., in the chair. The other members present were—W. T. B. Lyons, Esq., J.P., David Taylor, Esq., Dr. Browne, J. Hamill, Esq., R. Greer, Esq., D. Walker, Esq., A. Hamill, Esq., S. Tierney, Esq., T. Gaffikin, Esq., Dr. Moore, Jas. Adams, Esq., R. Carlisle, Esq., A. Brown, Esq., G. Jackson, Esq., W. Trotter, Esq., and J. Harper, Esq.

VACCINATIONS

Mr. Boyce, Clerk, submitted the returns from the several district doctors, showing the number of cases in which they respectively performed vaccination during the last six months, and requesting the sanction of the Board for the payment of the doctors for their services.

Mr. Tierney—It is one comfort that we do not know whether these cases were performed or not.

The Chairman—That is the fault of gentlemen who do not attend to their business.

Mr. Tierney—They should all be done at the public dispensary station.

The Chairman—There is a register kept of these cases, and if any gentleman doubts, let him go and judge for himself.

Mr. Tierney—It is a ruinous system that we have adopted.

The Chairman—It is the law, and when you got the law changed you can alter it.

Mr. Tierney—I hope I will do that.

NOTICE OF MOTION

Mr. Tierney submitted the following notice of motion, which he said, he intended to move on that day fortnight:—

"I hereby give notice that I will propose the following resolution, for the adoption of this Board, on Tuesday, the 5th proximo. A meeting having been held on the 31st ult. by a society consisting of a few medical men calling themselves "The Ulster Medical Protective Association," at which it was resolved that they should petition both Houses of Parliament for amendments in the present Poor-laws, the following being the chief amendments that the doctors propose, viz.:—First. That the present medical inspectors should not only be continued, but actually increased in number, at large salaries of—say £500 per annum each. Secondly. That the salaries of the medical officer connected with each union should not be under

the control, or their pay arranged, by the representatives of the ratepayers and guardians of the poor, as is the law at present, but be transferred to the Poor-law Commissioners, and their pay fixed by them (of course, the Boards of Guardians to be the paymasters out of the rates). Thirdly. That each dispensary doctor should get, in addition to whatever pay the Commissioners would fix, also a suitable allowance for the keep of a horse and car hire. Fourthly. That dispensary doctors should be the only parties appointed as registrars of births, deaths, and marriages in Ireland, at a suitable salary, in addition to their other salaries and vaccination fees. Seeing the strong efforts about to be made by the Medical Society (more properly called by the public a Trades' Union Association) to carry out the aforesaid termed amendments, whereby the rates of this union would be largely increased and a fresh mortgage imposed on the property of the union, it behoves us, therefore, as guardians of the ratepayers' money, at once to have petitions prepared for both Houses of Parliament to oppose these intended innovations, as proposed by the aforesaid medical association—the petition to the House of Commons to be forwarded for presentation to Sir Hugh M. Cairns, M.P., and that to the House of lords to the Marquis of Donegall."

Mr. Tierney hoped the Guardians would all attend on that day fortnight.

The Chairman—They will all get due notice of it,

Mr. Greer—These notices are so long that perhaps it is intended to receive tenders for printing them. (Laughter.) What does Dr. Browne say to this notice of motion?

Dr. Browne—Silent contempt!

Mr. Tierney—I will make it not silent contempt before I have done.

Dr. Browne—What business have the Board of Guardians with this matter?

Mr. Tierney—What business have the doctors with it?

The Chairman—Silence, gentlemen.

Dr. Browne—I have not addressed a word to this person.

The Chairman—You have committed a mistake in a term which you employed.

Dr. Browne—I did not say a single word to this gentleman at all.

The matter then terminated.

EDITORIAL

Belfast Daily Mercury 1 May 1861

The Ulster Medical Protective Association, at a meeting held yesterday [31 April 1861], resolved, we are glad to state, to proceed under the Medical Act against Mr. Johnston as not being a legally qualified practitioner. The clause in the Act applicable to this

case is clear and precise. The 40th section enacts that—

“Any person who shall wilfully and falsely pretend to be, or take or use the Name or Title of a Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Bachelor of Medicine, Surgeon, General Practitioner or Apothecary, or any Name, Title, Addition, or Description implying that he is registered under this Act, or that he is recognised by Law as a Physician, or Surgeon, or Licentiate in Medicine or Surgery, or a Practitioner in Medicine, or an Apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding £20.”

This clause is comprehensive and explicit enough, and it remains to be seen whether a person who is not registered under the Medical Act, who is not recognised by law as a “legally qualified Medical Practitioner,” can with impunity describe himself as such in a way to impose on the poor.

This question no doubt intimately concerns the honour, and dignity, and usefulness of the Profession in all its branches; but, at the same time, it vitally affects the interests of the poorer classes, among whom unqualified practitioners principally find their dupes. It is, therefore, in the interests of the poor that we applaud the action of the Protective Association, which, by fearlessly performing its duty, will merit the approbation and support of the public, not to speak of all the members of the Profession who regard its purity, and are desirous of upholding its character.

There is one matter to which we must allude, as suggested by the melancholy case of Mrs. Glynn. Respectable people in humble circumstances have a laudable pride in what is called “paying their way.” They do not like to have recourse to Dispensary aid, or to receive anything like eleemosynary assistance, even in illness, as long as they can pay for medical advice.

This, we repeat, is a highly laudable feeling, and ought to be cultivated and encouraged as much as possible. But like any other good feeling it may be carried too far, or wrongly applied, and thereby expose them to serious injuries. It was this feeling that led Mrs. Glynn to employ Johnston to attend in her confinement. He got his fee, paid two visits subsequently, and left her then to chance—even when sent for, he refused to see her again.

Now, for people in Mrs. Glynn's rank of life there is that admirable institution, the Lying-in-Hospital. They are only able to pay a fee of 5s, 7s 6d, or 10s for attendance during confinement; and the result is, a low class of practitioners, both qualified and un-qualified, are encouraged, who are neither creditable to the Profession nor serviceable to society; whereas, by availing themselves of the great advantages of the Lying-in-Hospital, they can have the first advice in Belfast. They can be admitted into the Hospital or

attended in their own homes, and may repose with perfect security in the consciousness that they have at command, in any extremity, the professional services of gentlemen of knowledge, skill, and experience.

This admirable institution is not sufficiently known among the humbler classes of society in Belfast, and we think some means—by the circulation of handbills, or otherwise—ought to be adopted to make them acquainted with its great advantages. The feeling that parties who avail themselves of its advantages are thereby accepting charitable aid, is one that ought not to be entertained, but those who cannot avoid such a feeling can easily satisfy it by subscribing to its funds the amount of the fee they would otherwise pay, perhaps to an unqualified pretender.

This is a matter of great social moment to the respectable classes of our industrial population. We do not allude to those whose necessities compel them to have recourse to Dispensary aid, but to those who are in comparatively comfortable circumstances, and are desirous of maintaining a respectable independence. It is for the wives of such persons that the Lying-in-Hospital offers advantages it is impossible for them otherwise to obtain.

COURT ACTION

Dublin Medical Press 22 May 1861

BELFAST POLICE COURT.

(Before W. T. B. Lyons, Esq., J.P.)

CHARGE AGAINST A

NON-REGISTERED MEDICAL PRACTITIONER.

Robert Johnston of 117, Durham-street, appeared on summons to answer the complaint of Surgeon Browne, Honorary Secretary to the Ulster Medical Protective Association, “That he did wilfully and falsely pretend to be a surgeon at Belfast, in the county of Antrim, on the 8th of April, 1861, and also on the day previous and on the day subsequent thereto, and did at the same time and place take or use the name or title of surgeon, he, the said defendant, not being a registered medical practitioner within the meaning of the Act 21 and 22 Vic., chap. 90.”

Mr. Seeds and Mr. McLean appeared for the prosecution, and Mr. Young for the defence.

Dr. Patterson and Surgeon Browne attended to watch the case on behalf of the Ulster Medical Protective Association. Mr. Seeds briefly stated the case for the prosecution.

Mr. McLean then produced a card containing the following intimation:—“Mr. R. Johnston, Surgeon, Accoucheur, &c., 117, Durham-street. Particular attention given to the diseases of women and children.”

Eliza Hamilton, examined by Mr. McLean—I know Mr. Johnston; he attended my sister, the deceased; he lives in 117, Durham-street. When my sister took ill, I went to Mr. Johnston, in consequence of a card having been sent to my sister's house. I presented that card to him.

To Mr. Young—I cannot read.

To Mr. McLean—I afterwards gave the card which I presented to Mr. Johnston to Dr. Corry. When I went to Mr. Johnston's house I asked him to come to my sister. I showed him the card I have referred to, and he gave it back to me. I told him how my sister was, and he said if she got worse to come back to him. He afterwards attended upon my sister. My sister died shortly after her confinement. Mr. Johnston was paid for his services before he left the room. He was paid 7s. 6d. That was all he demanded. He keeps a shop—like an apothecary's shop—at his own house.

Cross-examined by Mr. Young—My sister had been ailing for some time. I cannot read that card [produced]. The card given me by Mr. Johnston I brought home. I left it on the shelf in my sister's house. I will not swear that this [produced] is the card.

Mr. Lyons—All that this witness has proved is that the man Johnston attended her sister, prescribed medicine for her, and received his fee. That woman's evidence broke down altogether. She said she left the card on a shelf in her sister's house. She could not say whether the one produced was the one she presented to the defendant or not. It might have been changed fifty times for all she knows of it.

Dr. Corry was next examined, and deposed that he did not know whose handwriting was at the bottom of the card produced, that the deceased died from tetanus, and that he had attended her.

Nancy Hamilton, examined by Mr. McLean—I live in Stanfield-street; the deceased was my sister-in-law; I was in her house when she was confined, but not longer; Mr. Johnston was the medical man who attended her; I called him doctor; I cannot read writing, but I can read what is on this card [produced]. I see on it "Robert Johnston." I never saw the card before: he was present when my sister was confined: he did not prescribe medicine for her while I was there; he got his fee.

Mr. Lyons said he had not yet any proof before him that the defendant intended to pass himself off as a medical man. The evidence of the first witness was, that she had gone to Mr. Johnston's with a card, that he had prescribed medicine for her sister, and that he had received a fee of 7s. 6d.

Mr. McLean—She said she went to Dr. Johnston's, and that, in consequence of her presenting some card, he said: "Come back if your sister is worse." She went back to him, and he attended the deceased during her confinement, and prescribed medicine for her.

The second witness proved that during her confinement he attended deceased.

Surgeon Browne then handed in the Medical Registry, on which the defendant's name did not appear.

Mr. Seeds—We close our case now.

Mr. McLean—No: we will reëxamine the first witness.

Mr. Young objected to this, observing it was quite wrong to reëxamine witnesses in a penal case such as the present, particularly when nothing arose out of the cross-examination.

Mr. McLean said that the statute under which the prosecution was brought was one passed for the purpose of preventing the public being imposed upon by parties pretending to be able to render proper assistance to sick persons.

Mr. Seeds—One of the witnesses proved distinctly that Johnston acted as a medical man, and received a fee for his services.

Mr. Lyons—You have not proved that he was there as a medical man. The evidence is certainly not conclusive on that point. This card is, of course, the main thing to rely upon to show that he went there as a medical man, and the woman who went to him with the card cannot read, and will not swear that was the card she showed to him.

Mr. McLean—We submit that this person keeps a shop in Durham-street, and that that shop is an apothecary's shop—that he has been addressed by the witnesses here as doctor, and answered to that name—that the deceased was in childbirth, and that the card taken by Eliza Hamilton to him was the identical card presented afterwards to Dr. Corry.

Mr. Lyons—The question is, did he practise and wilfully and falsely pretend to be a surgeon. I do not think we have strong evidence of that.

Mr. McLean—We thought it was only necessary to bring him before the court.

Mr. Lyons—Is there any name over his door?

Mr. McLean—No.

Mr. Lyons—If this man is disqualified, I am here to punish him if he has acted as a medical practitioner.

Mr. Seeds then recalled the first witness.

Mr. Young objected to her being examined, and observed that the case for the prosecution, which rested upon the identity of the card, had signally failed.

After some discussion between the Bench and the legal gentlemen engaged in the case,

Eliza Hamilton was recalled, and in reply to questions put to her by Mr. Lyons, stated, with much reluctance, that she was in the room when her sister was confined, that while there the defendant said to her that something was wrong with her sister, and that he would be obliged to use means to remedy it, which he accordingly did in her presence.

Ulster Medical Protective Association

1860–1861

Chairman William M'Gee

Mr. Lyons said he thought he had now quite enough of evidence for the prosecution to show that the defendant had certainly acted as a medical man.

Mr. Young then addressed the Court at some length for the defendant, contending that no evidence had been given to prove the charge made against his client—namely, that he had wilfully and falsely used the title of surgeon in violation of the Act.

No witnesses having been examined for the defence, and after some discussion between Mr. Young and the Bench as to what “pretending to be” a surgeon meant,

Mr. Lyons postponed judgment in the case for three months, in order to afford the defendant an opportunity of qualifying himself; and if, in the meantime, he should be convicted of practising as a surgeon, he would fine him in the full sum of £20 for every such offence.

Mr. Seeds said that Browne did not wish to press the case, and that he was quite satisfied with the course taken by his worship.

Mr. Lyons—I know myself that all the association want is to have properly-qualified men for the public.

SECOND ANNUAL MEETING
Dublin Medical Press 22 May 1861

On Thursday, the 9th inst., the Annual Meeting of the members of the Ulster Medical Protective Association was held in the library of the General Hospital, at twelve o'clock, Dr. McGee, J.P., in the chair.

The minutes of the previous meeting were read and confirmed, and letters of apology for non-attendance were announced from Dr. Filson, Dr. Kidd, Ballymena; Dr. Davis, Newry; Dr. Jamison, Newtownards; Dr. McIntire, Coleraine; Dr. Neeson, Aghalee; Dr. Maxwell, Derrylinn; Dr. Ferris, Larne; and Surgeon McGreevy, Antrim.

Surgeon Browne, hon. sec., read a letter which he had received from the Secretary of the Irish Protective Association, stating that the next annual meeting of that body would be held on the 3rd June next in the Royal College of Surgeons, when several matters of great importance to the profession and the community in general would be brought forward, and expressing a hope that the meeting would be largely attended by country gentlemen.

On the motion of Dr. McLaughlin, seconded by Dr. Warwick, the letter from the Irish Protective Association was referred to a committee to take whatever steps might be considered desirable in the matter.

Surgeon Browne then read the following Annual Report:

“The Committee, in meeting the members of the Association after the lapse of twelve months, beg to submit the following report of their proceedings.

During the year eleven ordinary and two special meetings have been held, and the following is a summary of the business transacted at these meetings. At the meeting held on the 17th of May, 1860, it was deemed advisable to have a form of notice lithographed, a copy of which the Secretary was directed to send to every unqualified person practising medicine or surgery, and against whom a complaint had been sent in. The annexed notice was therefore adopted:—

‘MEDICAL PROTECTIVE ASSOCIATION.

Sir,—I am directed by the Committee of the Ulster Medical Protective Association to inform you of a complaint which has been made to them, “that you assume a professional title, and practise medicine without any legal right to do so,” and as your name does not appear in the Medical Register, I have to request that you will send to me a statement of your professional qualifications, that I may submit the same to the Committee. Should you not comply with this request, I am directed to say that this Association will take such steps as our counsel may advise in your case.’

The Secretary has reported that he has sent a copy of the preceding notice to twenty-one persons who were reported to the Committee as practising without any legal qualification. In the majority of instances these letters have had a good effect, either in eliciting from the persons complained of satisfactory replies, or in compelling them to abandon open practice. Soon after the last annual meeting the Secretary, by direction of the Committee, prosecuted three persons for illegal practice—one of them was ordered to register or be fined, one fled from town, and the prosecution against one was withdrawn by advice of counsel. But the Committee have the gratification to state that against this same individual, who continued to violate the law, a conviction was recently obtained, inasmuch as he has been directed to qualify for registration, if he can, within three months, or incur the full penalty, and in the meantime he is not to attempt to practise. These results are so far satisfactory that they prove that where an instance of illegal practice can be brought home to an unqualified man he will likely be convicted; but it is evident that the law, as it now stands, should be amended, so that unqualified persons practising medicine could be more summarily dealt with than at present, and with this view the Association lately joined the London Medical Registration Association in a strong and urgent memorial to the General Medical Council, calling upon them to take steps to have the Medical Act, 1858, amended accordingly.

In June the Committee sent forward a petition on the Registration Bill, which was presented to Parliament by Sir Hugh Cairns; and at a special meeting,

held the same month, they adopted a series of resolutions relative to the Registration Bills, then before the House, complaining of the penal clauses against medical men, and respectfully calling upon the Members of Parliament for Ulster to use their influence to have the obnoxious clauses withdrawn. In August both Bills for the Registration of Births and Deaths in Ireland, along with the Medical Charities and Poor-law Amendment Bills, were for the time abandoned.

Again this session, Mr. Cardwell and Lord Naas have introduced Bills for the Registration of Births, Deaths, &c., in Ireland. The Committee, on the part of the Association, have expressed their approval of the general principles of the Chief Secretary's Bill; and as it and that of Lord Naas have been referred to a Special Committee of the House, your Committee have taken steps to have witnesses from this Association examined relative to the contemplated provisions of these measures: meantime they recommend that a form of petition similar to that drawn up by the Cork Association be presented on behalf of our body—

‘TO THE KNIGHTS, BURGESSES, AND CITIZENS IN
PARLIAMENT ASSEMBLED.

The petition of the undersigned medical practitioners humbly sheweth,—That petitioners highly approve of the general principle of the Bill for the Registration of Deaths, Births, and Marriages, brought into your honourable House by the Right Honourable the Secretary for Ireland and Mr. Bagwell, and that petitioners will always feel it their duty to carry out, as far as in them lies, the provisions of the Bill, being convinced that the interests of science, and of their own particular profession, as well as those of the community in general, will be thereby served. That petitioners, however, at the same time, feel that a particular clause (the 43rd) in said Bill, will bear hardly on the profession at large, by imposing a penalty for not furnishing within a limited period a certificate of the death of a party on whom they may have been previously in attendance, and subject them to legal prosecution, even where infraction of the clause may arise from causes over which they in their professional avocations have no control, and thereby, in addition to the penalty, put them to serious costs.

That petitioners, therefore, humbly pray your honourable House to have the said 43rd clause either expunged from the Bill, or so modified, that it will not lead to punishment, for what may be a mere unintentional omission on the part of medical practitioners. And petitioners will ever pray.’

The Committee have recently, through your Secretary, had communications from several influential members of the Legislature relative to having the views of the profession in Ulster brought before the Committee of the House of Commons, now inquiring

into the working of the Irish poor-laws, and specific promises have been given that witnesses will be examined upon those points which affect the medical profession. That your Committee might be in possession of the sentiments of a large number of medical men, and thus be prepared to come before the Legislature with something of a specific character, queries were submitted to every medical officer in connexion with work-houses and dispensaries in Ulster. Replies were returned from a large number, and from these a special report was submitted to an extraordinary meeting of the Association, held in the month of January. At that meeting several important resolutions were passed, but as these have been published in the journals they need not be repeated here.

Since then an appeal has been made to all the medical gentlemen in connexion with the poor-laws in Ulster, asking for subscriptions to aid the Association in defraying parliamentary and other expenses connected with matters specially affecting their interests, and the treasurer will be able to inform the Association in what way the appeal has been responded to. Before closing this report, your Committee may say they have every reason to believe that the Association has done much to promote the interests of the public as well as those of the profession. They consider that in promoting the interests of the medical practitioner, who is called to administer to the wants of the sick poor—whose protector the doctor is—they benefit the entire community. In protecting the humbler classes of society from the rapacity of unqualified persons and sordid quacks—the working classes being peculiarly liable to be victimized by these pretenders—your Committee are convinced the various medical associations have effected unquestionable good, and they hope that this, as well as every other similar Association, will continue their best efforts in pointing out to the Legislature and to the public those matters which their education and experience show to be either beneficial or prejudicial to the community. Hitherto this Association, since its formation, has worked harmoniously with the other medical societies of the kingdom. To the Cork Association and the Council of the Medical Association for Ireland, your Committee are indebted for many useful suggestions and friendly acts, and they beg here to record their thanks to Dr. Armstrong, the indefatigable Secretary at Cork, to Dr. Quinan, the courteous Secretary of the Irish Council, and also to Dr. Mackesy of Waterford, the tried, energetic, and unwearied friend of the medical profession. In conclusion, your Committee trust that the meeting this day will urge upon the entire profession of Ulster the propriety of becoming members of the Protective Association, and thus aid in establishing the position they should hold in society—namely, a united body, protecting their own interests, and at the same time coöperating to

Ulster Medical Protective Association

1860–1861

Chairman William M'Gee

advance every measure by which the welfare of the public may be promoted. By order of the Committee, Samuel Browne, Hon. Sec.”

Professor Ferguson moved that the report and statement of accounts be adopted and entered on the minutes.

Dr. Rankin seconded the motion, which passed.

Surgeon Browne moved that Dr. Stewart be appointed Chairman of the Association during the ensuing year.

Dr. Michael McGee, in seconding the motion, said the Committee had carefully discharged their duty in watching over the interests of the profession during the past twelve months. It would be well if he could say as much for the profession. There were in Ulster 490 registered practitioners. They had in the county Antrim, of course, including the 85 practitioners in town, 120 members, and in Down there were 81. It must, therefore, be admitted from these calculations that the Association had, comparatively speaking, received very little support from the profession generally.

The motion was then carried by acclamation.

Dr. McGee said he had great pleasure in vacating the chair in favour of Dr. Stewart. From the experience he had had of his valuable services, his energy and strict attention to the interests of the profession—interests by which he could not be personally benefited—they might rest assured that the duties of the chair would be performed in a much more efficient manner than they had been since the formation of the Society. He did not resign the office from any unwillingness on his part to give his services, but having so much time occupied elsewhere, he thought that no man should enjoy the honours of the office unless he performed strictly the duties connected with it, and he felt that during the next year he could not do that. He was sure that Dr. Stewart would be able to perform efficiently all the duties he would be called upon to discharge. He had great pleasure, therefore, in making room for him.

Dr. Stewart begged to tender all present his best thanks for the great honour they had conferred upon him, he must say unworthily. Nothing could give him greater pleasure than doing everything in his power for the advancement of the interests of the profession, and he considered that in advancing the interests of the profession they were advancing the interests of the public at large. He was sorry to hear from Dr. Michael McGee that they had so small a number of members, especially now when bills of such magnitude concerning the interests of the profession at large were before Parliament. He concluded by again returning thanks to the meeting for having appointed him as chairman for the next year.

The committee and officers were then reëlected.

Dr. Stewart was called to the chair, and on the motion of Dr. Ferguson, the best thanks of the Association were offered to the late chairman.

Dr. McGee acknowledged the vote of thanks.

The proceedings then terminated.

COMPILER'S NOTE

Despite the evidence above of an interested and thriving society, no further reports of the proceedings have been found. Dr. Esler suggested in 1886 that the last meeting was in May 1862:

ULSTER MEDICAL SOCIETY
EXTRACT FROM
“PRESENTATION OF PORTRAITS”

Northern Whig 3 August 1886

Dr. Esler then said_ “...The Ulster Medical Society was constituted on 4th May, 1862, by the amalgamation of the Belfast Medical Society—a society which had been in existence from 1806—with the Clinical and Pathological Society, which was originated in 1853 by Dr. Malcolm. Another society, called the Ulster Medical Protective Association, with Dr. Samuel Browne as secretary, was also in active operation up till that time. Its last meeting was held in May, 1862, so that it also merged into the new society.”¹

Its merger into the Ulster Medical Society is also documented in a newspaper report of Professor J. C. Ferguson's opening address:

ULSTER MEDICAL SOCIETY
INAUGURAL ADDRESS

Belfast News-Letter 3 November 1862

Saturday last [1 November 1862], at three o'clock, the first Winter session of this important provincial association of medical practitioners—being an amalgamation of the parent “Belfast Medical Society” (founded in 1822), the “Belfast Clinical and Pathological Society,” and the “Ulster Medical Protective Association”—was inaugurated in the society's rooms, 33, High Street, by an excellent address from the president, Professor Ferguson, of the Queen's College, Belfast.

On the other hand there are two reports which suggest that there was still some activity by the Association after this. The first is from Dr. John S. Drennan's presidential address in 1866 where he says: “Those, however, who may wish to enforce the law against unqualified practitioners, will find facilities for doing so in the Medical Protective Society, which is amalga-

¹ [The fact that he knew about the meeting suggests that he may have had access to the minutes.]

mated with our own”.¹ The second is a newspaper report of a meeting in Banbridge in 1868:

BANBRIDGE UNION MEETING
Northern Whig Belfast 1 June 1868

Banbridge, 21st May, 1868.

At a meeting of the medical officers of Banbridge Union, held at the Downshire Arms Hotel, on the above date—Present—Dr. Malcomson, in the Chair; Dr. Tyrrell, Dr. Harman. Dr. Weir, and Dr. Crawford.

...

3rd. That—“A copy of these Resolutions be sent to ‘The Irish Medical Association,’ and to ‘The Ulster Medical Protective Association,’ requesting their advice as to our future proceedings, and their co-operation with us...”

Records
Of the
Ulster Medical Society

INTRODUCTION

The Ulster Medical Society was formed in 1862 by the amalgamation of the three medical societies already described in this book. There is a regrettable lack of information in the various minutes as to when this union was first contemplated and in particular, how it was negotiated.

It certainly had been anticipated by Malcolm nearly six years before when in a reply to a toast "The Belfast Clinical and Pathological Society, and its founder, Dr. Malcolm" proposed by Dr. McGee at the 33rd Annual Dinner of the Belfast Medical Society on 10 June 1856, he was reported to have said that "he thought the time was not very far distant when one great society might be formed by amalgamating the parent Medical Society and the Clinical together, which might be made productive of enlarged benefits and advantages to the whole profession"¹

Malcolm died three months later on 19 September 1856 of congestive heart failure secondary to rheumatic mitral and aortic valve disease. Presuming that he was aware of the seriousness of his condition when he rose to reply to the toast, it seems reasonable to suppose that he chose his words carefully to reassure those in the future who had to decide the fate of "his" society.

Samuel Browne, R.N., referred to the matter again in his Presidential Address to the Belfast Medical Society on 1 June 1857 when the minutes record "He concluded his excellent address by urging the expediency of a union of the Medical and Clinico-Pathological Societies—the preliminary consideration of this, as of the other measures previously recommended, being left to the Council."²

Council subsequently reported to the annual general meeting on 3 May 1858 that "As it does not at present seem easy to devise any plan for the amalgamation of the two Societies agreeable to the members of both, it is satisfactory to believe that whilst in the promotion of medical science they profess a common object, they have likewise each its own special sphere of utility which it may effectively fill without touching on the province of the other."

Dr. Murney raised the subject with the Society in July 1859 when it was re-referred back to Council but he had to report in August that it was not discussed due to an insufficiency of members at the intervening Council meeting.

The Belfast Medical Society was not attracting subscription-paying members in sufficient numbers to assure its future. The Report at the end of the 1860/61 session "expressed the regret of the Council that the affairs of the Society are not in a more flourishing condition, inasmuch as but one new member had joined during the past year, whilst one had died, another retired, and three others would become free members during the ensuing year."

Meantime, its proceedings were approximating those of the Clinical and Pathological Society. It is true that the former still had the medical library and that the latter still had the pathological museum and the analytical and microscopical committees, but both were now presenting cases at their meetings and both were publishing their proceedings (the Medical Society intermittently).

With similar problems, largely similar activities, and a limited pool of potential members, it made sense to consider amalgamation and the matter was raised again in September 1861 when the minutes of the Belfast Medical Society record "A discussion then took place relative to the advisability of amalgamating the Medical and Pathological Societies, a notice calling attention to same having been placed on the Monthly Paper, when after the greater part of the Members present had expressed their opinion, Dr. Browne moved, and Dr. Pirrie seconded the following motion which was passed unanimously—"That the Matter be referred to the Council to confer with the Council of the Pathological Society and prepare a plan to be laid before the next monthly meeting of the Medical Society"

That the Councils did confer is shown by the minutes of the Belfast Clinical and Pathological Society on 7 December 1861 when the "President reported the results of the labours of the Amalgamated Councils with reference to a union of the two Societies." (Incidentally, this seems to be the only certain reference to the potential amalgamation in this Society's minutes although a ballot, the result of which was announced on February 8th, 1862, may be relevant.)

By 3 March 1862, the Council of the Belfast Medical Society reported that it strongly approved of the proposed amalgamation, and referred to but did not minute the terms on which it would be effected. Later that month, a special meeting of the society was called and the chairman, Dr. Murney, "entered very fully into the subject, explaining the object and aims of the Combined Society as also the terms of subscription and minor matters of detail. He also dwelt upon the advantages of having a central reading room

¹ [Belfast News-Letter, 13 June 1856, p2.]

² [See page 178. This point was omitted from the newspaper reports.]

and making the Meetings of the Society more interesting.”

Rapid progress was made thereafter with four meetings of the society being held in April, the last one on 30 April being held jointly with the Belfast Clinical and Pathological Society. At it the following resolution was approved—“That this Meeting approve of the proceedings already undertaken for the amalgamation of the Medical and Pathological Societies, and hereby declare the union of the respective bodies under the title of the ‘Ulster Medical Society.’”

In his presidential address to the new society on 1 November 1862, Professor Ferguson acknowledged that the Ulster Medical Protective Association was included in the amalgamation but there are no references to this in the minutes of any of the three parent societies.

In 1859 the Medical Society had 55 members and the Clinical and Pathological Society 99, with 31 being members of both. Assuming that the numbers in 1862 were similar, the newly formed Ulster Medical Society probably had about 120 members. It might be expected that the new Society would attract more members and eleven applications for membership were indeed put forward to the first meeting. The initial level of the annual subscription is unknown but a few years later, in an effort to encourage new members, it was suggested that the subscription for town members be reduced to one guinea. While this was significantly more than the subscription for the Clinical and Pathological Society, it was actually less than the subscription to the Medical Society in 1822. The combination of the greater number of members and the higher subscription meant that the Ulster Medical Society was in a stronger financial position than either of its two main predecessors.

Ulster Medical Society
Session 1862–1863
President John Creery Ferguson

ULSTER MEDICAL SOCIETY

SESSION 1862–63

**Copy of Minutes of the Last (Joint) Meeting of
The Belfast Medical and the Belfast
Clinical and Pathological Societies**

30th April, 1862

Special Meeting Medical and Pathological Societies

Present, Dr. Stewart, Chairman, Browne, Smyth B, Cuming, Ferguson (P.), Wheeler, Patterson, Murney, MacCormac, Moore D, Johnston (P.) and Whitaker. (Those marked “P” are members of Pathological Society only).

Dr. Browne moved and Dr. Patterson seconded the following resolution—“That this Meeting approve of the proceedings already undertaken for the amalgamation of the Medical and Pathological Societies, and hereby declare the union of the respective bodies under the title of the ‘Ulster Medical Society’”.

The Ulster Medical Society

Meeting 30th April, 1862

Continued

The new Society having then been formed, Dr. Murney moved and Dr. Cuming seconded the following resolution “that the code of rules of which a copy had been sent to every Member of the Society be the laws of the Ulster Medical Society by which it shall be conducted”—passed unanimously.

The subject of the Annual Dinner having been then taken up, some discussion ensued, and the general feeling of the members being in favour of its taking place about the Commencement of the Winter Session, Dr. Murney moved and Dr. Patterson seconded—That the Annual Dinner be held on the first Saturday in November—passed unanimously. Dr. Murney moved and Dr. Ferguson seconded—That the resolution previously passed for the taking of central rooms for the use of the Society at 33 High Street be confirmed—passed unanimously.

Dr. Browne [moved] and Dr. Patterson seconded—that a subcommittee consisting of Drs. Murney, Patterson, MacCormac, Moore D., and Whitaker (three to be a quorum) be appointed to make the necessary arrangements for suitably furnishing the rooms—passed unanimously.

It was then arranged that the Annual Meeting be held on Saturday 3rd prox. at 3p.m. and that a Circu-

lar be issued summoning the members and signed by Drs. Whitaker and David Moore, as Secretaries pro tem, and that at that Meeting the reports and accounts of the two late Societies be brought forward and the office bearers of the “Ulster Medical Society” for the ensuing year duly elected.

Saturday 4th [sic] May 1862

The first meeting of the Ulster Medical Society was held in the library of the General Hospital, on Saturday 4th [sic] May at 3p.m., when there were present, Professors Ferguson, Gordon, Reid, Drs. Browne, Murney J.P., Mulholland, Corrie, Johnston, McGee J.P., Stewart, Patterson, Pirrie, J. W. T. Smith, W. MacCormac, David Moore, Dill, Brice Smyth, Bryce, Michael McGee, Murray, Scott J.P., (Aughnacloy), Halliday and Whitaker.

Dr. Stewart having been called to the chair; after some preliminary discussion, in which several members joined, and brought forward different subjects connected with the Society, among which the most important was the mode in which the election of office bearers should be conducted; as, however, the rules of the Society clearly defined same, it was decided that the elections take place in accordance therewith.

Professor Reid then moved and Dr. Dill seconded a motion for the adjournment of the meeting, which having been put from the chair, was lost, and Dr. Reade then moved and Dr. Michael McGee seconded, that Professor Ferguson M.D. be president for the ensuing year. Carried unanimously.

The President having taken the chair, the balloting then took place, and the following were respectively elected to the respective offices for the year 1862–63. Vice-Presidents, Drs. Browne and Wheeler, Country Vice-Presidents, Dr. Scott J.P. (Aughnacloy) and Dr. Graves (Cookstown). Council, Drs. Murney, Patterson, Pirrie, Cuming, Reid and William MacCormac. Treasurer, Dr. J. W. T. Smith. Secretary, Dr. Whitaker and Dr. Moore.

Dr. Moore then moved and Dr. Murney seconded “That a circular be issued to the members of the Profession in Ulster, stating the objects of the Society, and calling on them to enrol themselves as Members”. Carried unanimously.

The following gentleman were then proposed by Drs. Murney and Browne, as members, to be balloted for at next monthly meeting, viz Dr. Buckingham, Dr. H. S. Ferguson, Mr. T. Grattan, Mr. E. D. Gribbin, Mr. Morrow (Downpatrick), Mr. Thompson (Ballylesson), Dr. Dunlop (Holywood), Dr. Greenfield (Holywood), Dr. Hannay (Lurgan), Dr. B. Bindon (Coalisland), and Mr. Berry.

Dr. Cuming then read a vote of thanks to Dr. Halliday for the services he had rendered the Pathological Society in his capacity as treasurer of that body, Dr.

Patterson seconded the motion which was carried unanimously.

Dr. Halliday returned thanks and expressed his desire, at all times, to do his best to further the interests of the profession.

Dr. Cuming moved and Dr. Murney seconded a vote of thanks to Dr. William MacCormac and Dr. Moore, Secretaries of the Pathological Society for the services they had rendered that body, carried unanimously, both gentleman suitably acknowledged the compliment.

Dr. Pirrie moved and Dr. Patterson seconded a vote of thanks to Dr. Murney for the trouble he had taken in drawing up a plan for the amalgamation of the Medical and Clinical and Pathological Societies, and for the able manner in which he had carried same to a successful conclusion, carried unanimously, and Dr. Murney having thanked the meeting hoped that the Society would soon be in a flourishing and prosperous condition.

It was then arranged that the Council should meet on Wednesday 8th inst. at 3p.m. and the Secretaries were directed to issue notices accordingly.

J. Creery Ferguson, President

7th June, 1862

Present, Drs. J. C. Ferguson (President, in the chair), Browne, Pirrie, Dill, Patterson, Murney, Michael McGee, Dundee, Mulholland, William MacCormac, Brice Smyth, Stewart, Johnston, Wheeler, Warnock, Whitaker, and David Moore.

Resolved "That the standing orders of the Society, so far as regards the proposer of a member to be balloted for being held accountable for the payment of his subscription, being suspended for this meeting, to enable the proposed members to be balloted for".

The following were balloted for and duly elected viz Dr. H. S. Ferguson Belfast, Dr. Dunlop Holywood, Mr. T. Grattan Belfast, Dr. Greenfield Holywood, Mr. Buckenham Belfast, Dr. Hannay Lurgan, Mr. E. D. Gribbin Belfast, Dr. B. Bindon Coalisland, Mr. Berry Belfast, Mr. H. Thompson Ballylesson, Mr. Morrow Downpatrick.

Resolved, That the Secretaries be instructed to write to the gentlemen elected, informing them of their election and stating amount of subscription and that same is now due.

Resolved, That the Council be requested to report on the proceedings from the formation of Society at next monthly meeting.

Resolved, That (60) sixty keys for inside door be ordered for the use of the Society and that each member be provided with one gratis.

Resolved, That the Secretaries acknowledge receipt of letter from Dr. Armstrong, containing resolution relative to the registration clause in the new Bill of Sir Robert Peel passed by a meeting of the pro-

fession in his locality (Cork), state that it was brought before the meeting, and that steps have already been taken by the Ulster Medical Protection Society to bring the matter prominently forward.

Dr. Stewart gave notice of motion that the circular of ordinary meetings should in future contain a list of the office bearers of the Society.

Resolved "That the Members of the Ulster Medical Society beg to convey to their professional brother, Dr. Thomas Thompson of Wellington Park, Belfast, their sincere condolence and the expression of the deep sympathy with him under the painful bereavement which he and his family have recently sustained" and that the Secretaries be requested to send a copy of foregoing resolution to Dr. Thompson.

John Creery Ferguson, President

5th July, 1862

Present, Drs. Ferguson (President, in the chair), Thomas Reade, Stewart, Mulholland, Browne, Wheeler, Dill, William MacCormac, Murray, Michael McGee, Gribbin, David Moore, and Whitaker.

The minutes of last meeting having been read and confirmed, the report of Council was then brought forward, and after some discussion was adopted, that part of it relating to the library was, however, ordered to be reconsidered by the Council with a view to their marking proper regulations as regards the issue of the books, and seeing what steps could be taken to afford the Society proper security for the safe custody of same.

J. Creery Ferguson, President

2nd August, 1862

Present, Drs. Ferguson (President in the chair), Browne, Wheeler, Murney, Patterson, William MacCormac, J. W. T. Smith, Stewart, Ross, Gribbin, Beck, H. S. Ferguson, H. MacCormac, Arnold, Johnston, Dill, Michael McGee, John Smith, Corry, Brice Smyth, Mr. Aickin, Mulholland, Bryce, Murray, William Hanna, David Moore and Whitaker.

The minutes of last meeting having been read and confirmed, Dr. Rankin (Kircubbin) proposed by Dr. McGee (Michael) and seconded by Dr. Whitaker, and Surgeon Patrick (Carrickfergus) proposed by Dr. Wheeler and seconded by Dr. Whitaker, were elected members of the Society.

The following recommendation from Council was adopted "That the Secretaries be instructed to issue voting papers, on or before the last Saturday in April, in each year, to all members of the Society resident without the Borough-Boundary of Belfast to be returned to the Secretaries on or before the Friday preceding the Annual Meeting of the Society in May, but no vote for Office-Bearers can be received from any member whose subscription for the ensuing year has not been paid".

Ulster Medical Society
Session 1862–1863
President John Creery Ferguson

On the recommendation from Council that the following be substituted for Rule 11 “no member shall ballot, vote at any meeting of the Society or have the use of the library, while his subscription for the current year remains unpaid”;

Dr. Patterson moved, and Dr. Michael McGee seconded, that the Rule be amended as follows “No Member shall ballot or vote at any meeting of the Society while his subscription for the current year remains unpaid, but he shall be allowed the use of the library and rooms for the first three months of the said year, his subscription remaining unpaid”.

On the following motion having been proposed by Dr. Patterson, seconded by Dr. Wheeler “that the reading room be not open on Sundays” it was objected that due notice of said motion had not been given, thereupon the following notice of motion for discussion at next meeting proposed by Dr. Beck, and seconded by Dr. Johnston, viz “That the word daily in the report of the Council presented and passed at last meeting be not confirmed, as including Sunday and that in future the rooms be not open on Sunday.” was handed in; and it was agreed that in the meantime, until the question should be fully discussed the room should be closed on that day.

J. Creery Ferguson, President.

6th September, 1862

Present, Drs. Ferguson (President, in the chair), Patterson, Stewart, Drennan, Cuming, H. Moore, Arnold, Hanna, Gribbin, McCleery, James Moore, Michael McGee, Thomas Reade, Browne, Mulholland, D. Purdon, William Aickin, John Aickin, W. MacCormac, John Smith, Bryce, Patrick, Pirrie, H. S. Ferguson, Warwick, Alexander, Wheeler, Dill, J. W. Smith, Johnston, B. Smyth, Greenfield, D. Moore, and Whitaker.

The minutes of last meeting having been read and confirmed, Dr. Patterson moved and Dr. Wheeler seconded the following motion, “That the word ‘daily’, in the report of the Council presented and passed at last meeting, be not confirmed as including Sunday, and that in future the rooms be not open on Sunday”.

A discussion then ensued in which several of the members took part during which Dr. Michael McGee moved, and Dr. W. MacCormac seconded, the following amendment “That the outer door leading to the reading room and library be closed on Sunday and that a second latch be provided for same to suit the present keys for the convenience of members desirous of visiting the rooms on Sunday”.

A letter from Dr. MacCormac (Henry) was then handed to the President, directed to “the Members of the Belfast Medical Society”, several of the members objected to the reading of same and the sense of the meeting having been taken on the subject, it was decided, by a show of hands, that it should not be read.

Dr. Drennan then moved and Dr. Pirrie seconded the following amendment “That inasmuch as contrary opinions are held by members of this Society, as to the propriety of allowing access to its room upon Sunday, the Society, as a body, consider it inexpedient and unnecessary to make any rule (permission or restriction) on the subject; but allow to each member the right, and afford him the means, of acting in the matter according to his own judgement of what is befitting and convenient”.

A lengthened discussion then ensued, which was terminated by the President putting the amendments to the vote, both having been rejected, the original motion was then put and carried by a majority.

Dr. Browne and Dr. Patterson moved and seconded “That the Secretary be instructed to prepare an address to Dr. Heeney, on his departure for Queensland, expressing the esteem and respect in which he is held by the members of the profession, both in his private and public capacity, and their regret at his departure; and that same be laid on the table for signatures”.

A letter from Dr. Davey of Ballymacarrett having been handed to Dr. Whitaker, he, with the consent of the President, was proceeding to read same, when objections to its reception having been strenuously urged, it was ordered to be laid before the Council for their consideration.

John C. Ferguson, President

October 4th, 1862

Present, Drs. Ferguson (President in the chair), Patterson, Arnold, Beck, Stewart, David Moore, and Whitaker.

The minutes of last meeting were read and confirmed.

Dr. Arnold moved and Dr. Patterson seconded that the following be appended to rule 24, viz “That no rule shall be altered, rescinded, or new one introduced, except a monthly notice of such proposed change have been previously given”. Passed unanimously.

The arrangements to be made in connection with the Annual Dinner were referred to Council and the Secretary directed to summon a special meeting of that body to take the matter into consideration.

J. C. Ferguson, President

Special Meeting called by requisition

October 25th, 1862

Present, Drs. Dill (Chairman), Michael McGee, John Smyth, Corry, William Hanna, David Moore and Whitaker.

The requisition calling the meeting was read by the Secretary as follows “The undersigned members request the Secretaries will be so good as to call a meeting of the town members of the Ulster Medical

Society at the hour of 7 o'clock this day at the rooms, 33 High Street, for the purpose of considering whether the members of the Society, as such, should walk in procession at the funeral of the late Robert Bryce Esquire M.D., or not". R. F. Dill, John H. Halliday, Michael McGee. October 25th/62.

After a few remarks by the Chairman, introducing the subject of the meeting, Dr. David Moore moved and Dr. M. McGee seconded the following resolution, "That the members of this Society be requested to attend the funeral of the late Robert Bryce Esquire M.D. which will take place on Monday 27th inst. at 8½ o'clock a.m." And that circulars notifying same be issued to the town members. Passed unanimously.

J. C. Ferguson, President

November 1st, 1862

Present, Drs. Ferguson (Chair), Gordon, Browne, Dill, J. S. Reid, Hanna, Gribbin, William McGee, Patterson, Wheeler, Best, William MacCormac, Mulholland, J. W. T. Smith, Cuming, Michael McGee, Stewart, Johnston, David Moore and Whitaker.

The minutes of last meeting having been read and confirmed, the President then read an able and instructive address.

Paper.¹ Gentlemen,—The opportunity afforded me by this day's inauguration of the Winter Session of our Ulster Medical Society, I cannot permit to pass by, without again giving expression, however brief and faint, to the feelings of gratitude and pride which your unexpected as unmerited election of me to the honourable position of your President have inspired: gratitude for the courteous kindness of sincere, but, I fear, too partial friends; and pride, that even to them I should have appeared not altogether unworthy of so honourable and so distinguished a mark of confidence. For myself I could have wished that the duties of the Presidential Chair of a Society professionally so important as yours had devolved upon some member—and you have many such among you—more competent and better qualified than its present occupant to perform them efficiently and satisfactorily. When first you called me to this post of honour, I felt, and I still do feel, a consciousness of my own deficiency in many of the almost necessary requisites for such an office. Nevertheless, in an anxious desire to promote the best interests of the Ulster Medical Society, to endeavour, by every worthy means within my power, to establish and maintain it in a position, as well social as professional, worthy of our medical brotherhood of Ulster, I honestly avow I will yield to no man. Hence my resolution was at once taken; for, looking to and depending upon that support and encouragement from my fellow-members which good intentions are ever sure to command, I felt it almost a duty not to shrink from the attempt to fill

this chair, and I hoped not altogether unworthily. To accomplish this during the Session we are now entering on, shall be my chief aim and object; but I trust it will never be forgotten, that for that support and assistance in the performance of my duties, which I feel conscious of needing, I may ever look, perhaps appeal, to your kindness and forbearance, and satisfied am I, never appeal in vain.

Since we last met in this room death has struck down his victim from among us, and the place of our friend and fellow-labourer Dr. Robert Bryce, "knoweth him no more." He had been for many years a member of the Medical, and from its origin took an active part in the proceedings of our Pathological Society. Few of us have not had frequent opportunities of witnessing the good sense, the matured experience, the originality of thought and suavity of temper displayed by him in our discussions. If any of us felt the force and point of the bolt he shot, yet it brought with it no venom, and left no sting behind. His intellect was sound, his heart warm and true, his professional honour unsullied. The words of Horace, believed to refer to his immortal but eccentric friend Virgil, might perhaps not inaptly be applied to him—

Rusticius tonso toga defluit, et male laxus
In pede calceus hæret: at est bonus, ut melior
Non alius quisquam: ac tibi amicus, et ingenium
ingens
Inculto latet hoc sub corpore.

Let then his failings, and if any they were few, "be interred with his bones." Let the memory of his virtues, and they were many, "live after him," and to his ashes Peace.

For many years Belfast has been, I may say, rich in the possession of societies connected with our profession, into the particulars of whose history or circumstances, however interesting, it is not my present purpose to enter. Suffice it to say, that each had its own peculiar object, its own means of working out that object, and that it did so, I believe, assiduously and effectually; each society devoting itself more particularly to subjects connected with the scientific or the practical department of medicine and surgery; or to the guardianship and protection of the best interests of our profession.

'Tis now some time since the idea occurred to some members who have always taken an active part in the working of these societies, that their amalgamation might be effected, not only without impairing the usefulness of any, but rendering the working out of the objects of all, more facile, more agreeable, and at the same time, equally productive of good to our republic. In fact, many of us began to feel that we were rather hampered by what might be, with truth, designated an "embarrass des richesses." This idea spread rapidly among us, until it gradually assumed a palpable and a practical shape, eventuating, as we all now know, in

¹ [Dublin Medical Press, 1862, v , p722.]

Ulster Medical Society
Session 1862–1863
President John Creery Ferguson

the amalgamation of the three previously existing societies, to form the Ulster Medical Society, in which it is fondly hoped, that all the objects of its predecessors, I may say parents, shall be worked out; where the science of medicine may be pursued with unabated zeal; where the *ars medendi* may secure to itself all the interest, investigation, and attention, which its primary importance and utilitarian tendencies demand; and lastly, where the social status, the best interests and the honour of our noble profession may be jealously guarded and worthily maintained.

With respect to the first two of these objects, it may be that we do not habitually or sufficiently distinguish between them—I mean the science and art of medicine—and, as I have lately seen this well put, and briefly, in a paper on “Art and Science, a contrasted parallel,” by Dr. John Brown of Edinburgh, I would for a moment claim your attention to his “contrast” of them as applied to medicine. He says:

ART,
Looks to symptoms and occasions.
Is therapeutic and prognostic.
Has a method.
Is ante-mortem.
Looks to function more than structure.
Runs for the stomach-pump.
Submits to be ignorant of much.
Acts.

SCIENCE,
Looks to essence and cause.
Is diagnostic.
Has a system.
Is post-mortem.
Looks vice versa.
Studies the phenomena of poisoning.
Submits to be ignorant of nothing.
Speaks.

No doubt this may be somewhat arbitrary, but, in the main I think it is not far from the truth, and it has certainly brevity to recommend it. And with respect to the third, the maintenance of the honour and social status of our profession, that “in union there is strength,” few will deny. We have sought and accomplished this union of the “*membra disjecta*” of our profession in Ulster, and have we not a right to expect the natural consequences? Yes, gentlemen, and if we be but true to the honour and dignity which should be ours, true to what medicine has a right to expect—nay demand—from all who embrace her, true even to ourselves and our own selfish interests, the accomplishment of our union will inevitably confer power—ours it must be to take care and see that that power be well and honourably directed.

Confiding in the truth of the aphorism already alluded to, it occurred to some of our body that our union might be made more perfect, that we might be

brought more frequently and more directly in contact, and other desiderata effected by the establishment of Medical Rooms in a central situation, where a selection from the books of our library, medical periodicals, and a few of the more prominent journals of the day might be always readily accessible, making the rooms more attractive, and affording a convenient and useful rendezvous for the resident as well as country members of our Society.

That this has been carried out successfully, and that all the advantages anticipated from our possessing rooms presenting the attractions alluded to have been fully realized, needs no confirmation from me; but I do feel that to those gentlemen who took so much trouble, and so successfully, in “setting our house in order,” we owe a debt of at least gratitude and thanks. There may, no doubt, be some of us who think that non-professional journals and hebdomadals were superfluous, or not just suited to the atmosphere of these rooms—a matter of taste, about which, proverbially, non disputandum est. But I am apt to think that though most of us may be tolerably well-informed on the passing events of our own locality, yet that it would not be altogether valueless to us, or devoid of interest, that we should see from different points of view what others think and say of the world’s progress. Who that wants to be informed,—and to whom is such information more requisite than to the medical man?—who that wants to be informed on the daily march of events in the great world beyond this little “gem of the sea” of ours, can afford not to read the Times? Or can a man in our day be said to live, and not rather to exist, who, feeling that “*dulce est desipere in loco*” seeks not after his week’s work the solace of conning over the fun and frolic, the wit and wisdom, blended with the sound morality and virtuous purpose of the laughter-loving Punch? Sydenham, a high authority all will admit, when asked by Sir Richard Blackmore what medical reading he would advise, rejoined, “Read Don Quixote, Sir.”

And now I must pray you to bear with me whilst I briefly allude to the points which in my mind ought, and I think are most likely, to constitute the chief objects of our attention in the practical working of our Society. As I before hinted, I would classify them under three heads; as Theoretic Inquiries, or the science of medicine; Practical Facts, or the art of healing; and Professional Ethics.

These subjects, to their utmost limits, come within the scope of our investigations. The meetings of our Society, but more especially those held on Saturday during the winter session, offer favourable opportunities for the production of papers or for discussions on all new discoveries in medicine, or on theories as yet not fully developed or established. And here I hope I shall not be misunderstood, but excused in the liberty I take, when I pray that attention may be given to a careful separation of this class of subjects from what I have

designated Practical Facts. And I feel the rather justified in alluding to this matter, from the natural tendency of most, if not all, men's minds to receive with favour, perhaps partiality, the offspring of their own intellectual workings, and to accept as facts what it may be further investigation on their own part, or an appeal to the less prejudiced judgment of their brethren, might lead them to view in a very different light.

To observe in medicine, or in any other art, a genuine, honest, palpable fact, requires more strength and force of mind than to spin out any amount of fine theory or plausible hypothesis, or to build any number of, as Sydenham calls them, castella in ære, whose architect unfortunately can rarely be said

To know what's what: and that's as high
As metaphysic wit can fly.

In no other science is it more necessary that the process of induction be rigidly observed than in medicine. Let us have our facts first, and on them found our theories. This I believe to be the only path by which truth can be reached—truth, the aim and object of all our inquiries. And truth, to use the pithy words of one of Ireland's eminent sons,—“Truth is to be sought,” says Curran, “by slow and painful progress only. I know that error is in its nature flippant and compendious, hopping with airy and fastidious levity over proofs and arguments, and perching upon assertion which it calls conclusions.” Let us, my friends, endeavour to eschew this “error.” And let us ever remember that the stepping-stones to truth in medicine are well authenticated and unmistakable facts, entities, carefully to be distinguished from, and never to be confounded with, the mere opinions of those who observe and describe certain phenomena, and who are too apt to regard these mere opinions as facts. “Few persons,” says Louis, in his *Researches on Phthisis*, “are free from delusive mental tendencies, especially in youth, interfering with true observation; and I am of opinion that, generally speaking, we ought to place less reliance on cases collected by very young men; and, above all, not entrust the task of accumulating facts to them exclusively.”

We all have heard Cullen's pithy remark—even in his time it is to be feared too well founded—“that there are more false facts than theories in medicine.” And in his *Materia Medica*, he gives us a full and classified statement of the many mistakes and untruths which are drawn from what he calls “false experience.” Dr. Cullen, admitting that these “false experiences” were often mere mistakes of judgment, and not made in consciousness of their falsehood, yet hesitates not to reprobate, and with much severity, the manufacture of facts in medicine; and he concludes with a rather remarkable and trenchant statement: “This leads me to observe,” says he, “that a very fertile source of false facts has been opened for some time past. There is in some young physicians the vanity of being the authors of

observations which are often too hastily made, and sometimes perhaps dressed in the closet. We dare not at present be too particular, but the next age will discern many instances of perhaps the direct falsehoods, and certainly the many mistakes in facts, produced in the present age concerning the powers and virtues of medicine.” “Non meus hic sermo,” Gentlemen. These words, be it distinctly understood, were written so long since as 1789.

But it might suggest itself to inquisitive minds to calculate how far they were applicable to a later period in the world's history. “In this intensely scientific age,” writes one of our own day and generation, “we need some wise heads to tell us what not to learn or to unlearn, fully as much as what to learn. Let us by all means avail ourselves of the unmatched advantages of modern science, and of the discoveries which every day is multiplying with a rapidity which confounds; let us convey into and carry in our heads as much as we safely can of new knowledge from chemistry, statistics, the microscope, the stethoscope, and all new helps and methods: but let us go on with the old serious diligence—the experientia as well as the experimenta,—the forging and directing and qualifying the mind, as well as the furnishing, informing, and what is called accomplishing it. Let us, in the midst of all the wealth pouring in from without, keep our senses and our understandings well exercised on immediate work. Let us look with our own eyes and feel with our own fingers.” In other words, let us observe, record, and prize real facts.

From the long experience I have had of the working of the Pathological Society—whose very memory is still pleasant to me, as its meetings had ever been profitable and instructive—I think I am justified in believing that 'mid the subjects that may hereafter engage our attention “practical facts” will occupy a prominent place, and give to our meetings that interest which they have ever heretofore and deservedly elicited. Few of us, I ween, have attended many meetings of the old Pathological without carrying away with us more knowledge than we brought there; or without, at least, feeling that we had spent one hour of our week well. Nor do I think it would be too much to say that the application of the file to which we were all there subjected, and the necessary but wholesome collision of opinion there elicited, have proved often very effectual in making each of us, if not quite “totus teres atque rotundus,” at least somewhat more “factus ad unquem” than before. Be this as it may, however, it cannot be doubted that, as I have said, on these “practical facts,” carefully observed and rigidly investigated, must all theories be founded, and from them must all safe inferences applicable to the practice of our art be drawn. Judging from the past, may we not confidently look forward to a future copious and comprehensive supply of facts, cases, and objects in every department of medicine and surgery?

For my part, I am sanguine on this point, being satisfied that not only will our former contributors not fail us, but that we may reckon, and confidently, on the new blood transfused into our renovated system. But I would forewarn that “new blood,” and pray it to bear with me, while I suggest to it caution, circumspection, deliberation, even a study of the brilliant exemplar, if I may be excused the personal allusion, that has been set before it in the recorded autopsies of the old Pathological, giving, as they do, if properly appreciated, subjects worthy of the closest imitation, and whilst stimulating to increased industry and exertion on our part, yet proving too conclusively that “non cuius homini contingit adire Corinthum.

Permit me now, Gentlemen, to offer a remark or too on the subject of professional ethics, more especially in connexion with our relations to each other. As in other professions and callings, opposite interests and diversities of opinion lead to controversy and even contention, so in ours are they occasionally—happily not frequently—productive of similar results. Where such arise, I hold that conflicting opinions and views, differing upon points of professional etiquette, should be referred by both parties to a court composed of their peers, where their differences may be impartially and correctly settled; where right will be maintained and wrong set right; where in every case the disputants have such confidence in the court, that they bow to and abide by its decision; where all such investigations and awards are held as strictly private and confidential between the parties themselves and their brethren. Such a court, and such a means of adjusting professional disputes, our Society presents to the profession. I fear it were to take too Utopian a view of life as it is, to entertain the hope that such differences may not, nay will not arise.

If we were all to lay down as our rule of conduct that noble maxim enjoined by “the Great Physician”—“As ye would that men should do to you, do ye also to them likewise,” and in every circumstance of our professional path through life act up to it, then indeed would there be no need of the “court medical,” then were our code of ethics virtually a dead letter. But as “it needs must be that offences come,” all, I think, will admit that publicity is not likely to close or heal the breach, and that the private arbitration of professional friends is best suited to arrange differences satisfactorily, with less personal annoyance or injury to the disputants, and with less chance of discredit or obloquy being reflected on the profession; for I imagine that I but echo the sentiments of the majority in maintaining that bickerings and disputations between individuals must ever reflect unfavourably, or even injuriously, on the entire body.

We all know how almost proverbial for its bitterness and intensity the odium theologicum has ever been—that hatred of a man’s neighbour for the love of

God! Barely less intense, but certainly not less odious where it exists, will the odium medicum be ever found. But from that unhallowed combination, the monster offspring of both, “angels and ministers of grace defend us.” Nor among the means that have been recommended as likely to allay the virulence of, or it may be, even eradicate that malady, the odium medicum, so inveterate where it has unhappily been once engendered, can I on the present occasion pass over unnoticed one in particular,—a remedy which, whilst it will be by most of us recognized as efficacious, will be, I hope, adopted and acted on by all of us to-day as a most wholesome and agreeable specific, if there be such a thing as a specific in our materia medica. The British and Foreign Reviewer puts this so well, that I shall offer no apology for quoting and adopting his words. When speaking of this odious odium medicum, he says: “The true remedy for professional jealousies is frequent intercommunication. A good dinner at the “Royal” would heal the professional feuds of a large town. The man of science who thinks he practices his profession for the sheer love of it may smile at the sensualness of the means, and it may not be the remedy he requires; but most practitioners are the men of the “metier,” and like a dinner of the craft as well as others. We wish there were a medical guild in every large town, with an ample dinner fund; good fellowship would increase and abound, and with it unity of purpose, honour, public and personal esteem.” Gentlemen, these are sentiments and wishes in which, whilst I would urge them on your attention, I for one most heartily concur. Frequent intercommunication, unity of purpose, mutual and self-esteem, leading directly to honour and public respect, were “a consummation most devoutly to be wished.” I have but to add, Gentlemen, that our future meetings during this winter’s session will be held in the museum of the Society, at the General Hospital, every Saturday, at three o’clock.

Dr. McGee (Michael) moved and Dr. Browne seconded the following resolution, “That the address just read by the President be handed to the Secretaries to be printed by the Society, and distributed among the members”. Passed unanimously.

The Treasurer then read a statement of the financial position of the Society from which it appeared that he had received in subscriptions a sum of £62.9s.6d and had paid various accounts amounting to £57.1.6, leaving a balance in his hands of £11.8.-. He also stated that there were subscriptions still due amounting to about £20.- which with the balance in hands would make a total amount of 31.8.- to credit of Society.

Dr. Dill then stated that in consequence of the dis-ease of the late Dr. Bryce, co-auditor of the late Pathological Society he, in conjunction with Dr. Johnston had audited the account of that body and found

a balance remaining in Treasurer's hands amount £18.19.10.

J. Creery Ferguson, President

Report on the Inaugural Meeting and Dinner¹

On Saturday, at three o'clock, the first winter session of this important provincial association of medical practitioners—being an amalgamation of the parent "Belfast Medical Society" (founded in 1822), the "Belfast Clinical and Pathological Society," and the "Ulster Medical Protective Association"—was inaugurated in the society's rooms, 33, High Street, by an address from the President, Professor Ferguson, of the Queen's College, Belfast. The attendance of members on this interesting occasion was large and influential, and the eloquent address of the President was listened to with much attention.

In the course of his practical and excellent remarks, the learned Professor dwelt forcibly upon the subject of "Medical Ethics," and of each member making it his bounden duty to endeavour, not only to keep up, but to add to the high prestige of their honourable vocation—that each should remember that he represented a profession which, of all others, demanded the strictest and nicest sense of honour in their every action individually, and especially so as regarded their bearing towards each other.

He pressed also the necessity of united and active exertion in maintaining the interest and practical usefulness of their weekly meetings for professional discussions, observing, on this head, that already their proceedings, he could avouch, had attracted the attention of their brethren in distant places, and had called forth an expression of opinion more flattering to them as a professional body associated together for the advancement of science, which should be an additional inducement to stimulate them to increased energy in furtherance of objects so beneficial to themselves and the community at large.

At the close of this address, the cordial thanks of the meeting were, on the motion of Dr. Browne, R.N., voted to the President for its ability and excellence, with a unanimous request that he would permit it to be printed and circulated freely amongst the members.

The Treasurer of the Society (Dr. J. W. T. Smith) having next made a financial report of the number of members and state of the funds, which was of a most satisfactory nature, the meeting adjourned until the appointed hour for dinner.

Amongst those who were present at the meeting, besides those already named, we observed—Dr. Patterson, Dr. Whitaker, and Dr. David Moore (joint secretaries); Dr. Beck, Dr. M. Magee. Dr. H. Burdon, Dr. Cumíng, Dr. M'Gee, J.P.; Staff-Surgeon Saunders, 14th Depot Battalion, Belfast; Surgeon Gribben; Dr. Wheeler, Vice

President; Dr. C. Mulholland. Dr. Pirrie, Dr. W. MacCormac, Dr. W. Aickin, Professor Gordon, Queen's College, Belfast, Dr. R. Stewart, Dr. Dill, Surgeon Johnston, &c.

The Dinner

The inaugural dinner took place at five o'clock in the society's well-appointed room, the arrangements connected with which were carried out by Mr. Thompson, of Donegall Place, and in so effective a manner as to afford unqualified satisfaction, the dinner and dessert being everything that the most fastidious could have desired. The wines, too, were abundant and varied, as well as of excellent quality. Covers were laid for twenty-five. Several who intended being present were unavoidably absent, and of this number were Professor Burdon, Dr. Dunlop, &c.

The cloth having been removed, the Chairman (the President) gave, with appropriate prefaces, "The Queen," "The Prince of Wales and the rest of the Royal family," coupled with "The Bride Elect, the Princess Alexandria;" "The Lord Lieutenant and Prosperity to Ireland," to which toast Dr. M. Magee, having been loudly called upon to respond, replied in an excellent and very effective speech. "The Medical Officers of the Army and Navy," responded to by Dr. Browne, who, before sitting down, proposed "The Ulster Medical Society," coupled with the name of the President, the latter replying to it with much effect. "The Belfast General Hospital and the Belfast Lying in Hospital." Dr. Pirrie replied, who, in the course of his judicious and well-received remarks, said he regretted much there was not a better attendance of the staff of the General Hospital at their dinner that day, and at which all should, upon such an occasion, especially have considered it their duty to be present. (Hear.) "The Medical Schools of the Queen's Colleges in Ireland." Professor Gordon's name being coupled with this toast, that gentleman replied to it in a manner which elicited great applause.

The President, in giving the next toast, "The Medical Benevolent Fund Society of Ireland," coupled with the name of Dr. B. Stewart, said he could not do so in a merely formal manner, but would take that opportunity of most earnestly entreating every member of the profession to support that truly valuable society in carrying out its most beneficent and humane objects. (Hear, hear.) The Belfast branch of the society, he said, had hitherto done its duty creditably and liberally; but, though this was the case, yet if each member of the profession would make it his imperative duty to give something, be it ever so trifling, to its funds, a greatly increased aggregate amount would be the result; and the more he reflected on the all important services which this society was rendering, the more earnest desire he felt for its having the means at command for increased usefulness, and would accordingly desire to impress, with the utmost earnestness, upon every member of the profession, even the most straightened

¹ [Tyrone Constitution, 07 November 1862.]

in circumstances, to record his name as a subscriber to its funds. (Hear.) What they would give in this way would never be missed, and hereafter they would have a self-approving conscience for having done their duty towards their poor brethren. (Hear.) He concluded by calling upon Dr. Stewart to reply to the toast as the efficient secretary for a great number of years to this local branch of the society, and who, having shortly done so, begged to propose “The Health of the Vice-Presidents of the Ulster Medical Society.” connecting with it the name Dr. Browne, who was also the zealous treasurer of this branch of their benevolent society.

Dr. Browne replied in an excellent speech.

Dr. Patterson said that, in connection with the toast now given, he would propose “The Health of Dr. T. H. Purdon,” the permanent President of the Belfast Branch of the Medical Society, whose support of that invaluable body could not be sufficiently praised, his donations being really of a princely nature. (Hear.) Dr. Purdon’s health was drunk, accordingly, with the greatest enthusiasm by all present.

“The Memory of the late Drs. Dixon and Bryce”—drunk in solemn silence.

Amongst the other toasts of the evening were—“The Country Members,” “The Secretaries and the Treasurer,” “Dr. Patterson and the Stewards,” &c., &c.—all of which having been duly honoured, and an exceedingly pleasant and harmonious evening spent, the President left the chair, and the meeting separated at eleven o’clock, greatly pleased with the day’s entire proceedings—Northern Whig.

November 8th, 1862

Pathological Museum, General Hospital.

Present, the President in the chair, Drs. Browne, Patterson, Stewart, J. Moore, Cumming, Brice Smyth, Pirrie, Arnold, McGee, Whitaker, D. Moore.

The minutes of the previous meeting having been read and confirmed—it was resolved That the question of the publication of the transactions of the Society be referred to the Council, in order that they may consider same and report thereon at next meeting of Society.

Dr. Browne exhibited a case of congenital double cataract in a boy of six years of age.

Paper:¹ The child whom I now introduce to the notice of the Society is named James Hogan, 5 years of age, a native of Stewartstown, county Tyrone. He was blind from birth till very recently, when I performed the operation for promoting absorption of the cataracts, which it will be perceived have become partially absorbed. The right eye was operated on twenty-six days since, and the left fourteen. This case is an excellent illustration of what I stated to the Society last year, when I exhibited a lad on whom I had recently operat-

ed—namely, the propriety, nay, the necessity, of early operations in cases of congenital cataract, and before the eyes have acquired that rolling or oscillating motion so frequently observed in the eyes of those who have been born with cataract in each eye, and who have not been submitted to treatment until the age of ten years and upwards. The eyes in the child before the Society have not yet acquired much of that unsteadiness, and the little they have will readily be overcome by the use to which the eyes will be put after sight has been perfectly restored; perhaps, I should say, as perfectly as such cases can be restored to vision. I have no doubt that this boy will have good sight, and with the aid of proper lenses will be able to learn a trade and pursue such calling with ease and accuracy. I shall likely have to use the needle again in each eye, so as to promote complete absorption. I may remark that very little irritation—no inflammation—succeeded the primary operation; indeed, in these cases my experience is that inflammation rarely follows the operation.

Dr. Browne read notes of a case of femoral hernia.

Paper:¹ Before I relate the particulars of the case of hernia which I am about to bring forward, and which I deem of sufficient interest to occupy the attention of the Society for a little time, I beg to make a few observations on the subject of strangulated hernia. Every hospital surgeon of any experience must have observed that among all the cases of irreducible hernia requiring operation no two have been alike in all respects, and that in the steps of the operation he has had to be guided by circumstances differing in each case. Hence, every surgeon must be prepared to find something, not only not in accordance with what has been laid down in the books, but also essentially differing from cases of his own foregone experience. Now, the following case will be seen most strikingly to bear out these remarks, and is, I conceive, worthy of being recorded from the peculiar and rare features which it presented:—

Agnes McVeigh, aged 64, was admitted to the General Hospital on the afternoon of the 1st of August last, labouring under symptoms of strangulated hernia. She stated that for some years she had been troubled with a swelling in the right groin, which came on upon any exertion, and gave her great pain, but which she was always able to disperse by pressure and friction over the part when she was in the recumbent posture. She had never worn a truss, as she was ignorant of the nature, and especially of the danger, of the enlargement. About eight days before her admission to hospital, the hernia had come down, and she had not been able to push it up as usual. During that time the bowels had not acted, there was occasional nausea and vomiting, with severe intermitting pain. Three days preceding her reception into my ward the symptoms had become more severe daily, and the part exceedingly tender from

¹ [Dublin Medical Press, 1862, Dec 03, p549.]

¹ [Dublin Medical Press, 1862, Dec 03, p548.]

the continuous efforts that had been made, not by any medical man, to reduce the enlargement. Upon examining her, I found a hard tumour three inches in length by two in breadth, prominent and discoloured, extending above, and in the course of, Poupart's ligament. It was perfectly immovable, and very tender to the touch. The patient had constant nausea and frequent vomiting of bilious matter. I believe the ejecta had been stercoaceous. Her pulse was frequent and feeble, and her countenance denoted great prostration. There was also considerable tenderness over the abdomen, and great intestinal tympanitis. The patient previous to my arrival had been put into the warm bath, but there had not been made any attempt at reduction of the hernia. The history and circumstances of the case pointed out the nature of the affection, and that any attempt at reduction by the taxis would be quite inexpedient and indeed dangerous. I, therefore, determined to operate forthwith. For this purpose the patient was put upon the table and brought speedily under the influence of chloroform; and here I may remark that, as I had frequently observed before, the anæsthetic had the most marked influence upon the heart's action, causing it to beat more slowly and much more powerfully, the volume of the pulse at the wrist having been increased in a remarkable manner. Having made an incision of four inches in length in the course of the long axis of the tumour through the integument, I came down upon the cellular tissue, which was densely infiltrated, and felt under the knife as if it were cutting through brawn. The remaining steps of the operation brought me by a careful dissection of agglutinated tissues, quite inseparable into distinct layers, to the sac, which, contrary to my expectations, was very thin, and exhibited a mass of dark-coloured omentum within it. On opening the sac, a portion of omentum fully as large as half of the closed hand came into view. This I carefully lifted up and searched for intestine, but could not see any. I then put the point of my forefinger upon the seat of the stricture, which I found to exist at Gimbernat's ligament. This I divided by very light touches of the probe-pointed bistoury supported upon my finger. A few touches freed the strictured omentum, so far as to permit me to draw it gently down for the purpose of examining its condition. While doing so, and passing my finger up beyond the strictured point, I detected a small knuckle of intestine which was bound down, strangulated in fact, by a portion of the omentum, or a band of lymph. I then considered it was necessary to open the femoral ring more freely than I had done, so as to enable me to free this piece of gut, and to see its condition. Having enlarged the section in Gimbernat's ligament, I was enabled to bring down by gentle traction the piece of strangulated gut and to free it from its investing band. It was of a clear chocolate colour, and as it and the omentum that had been down were not seemingly much injured by the constriction to which they had for

several days been subjected, I returned the entire mass into the abdomen, and while doing so a considerable quantity of straw-coloured serum, highly coagulable, flowed forth. The wound was then brought together by the interrupted suture, and a compress supported by a bandage was accurately applied. The patient was removed to bed, and a sedative was given. I visited the patient at nine p.m. that evening, and found that although some of the more urgent symptoms and the depression had somewhat abated the bowels had not acted, and there was still rejection of the ingesta. I ordered a full opiate, hot turpentine stupes over the abdomen, and an enema of warm water to be administered with the view of clearing the lower bowel. Next day I found that three enemata had been given, but that the bowels had not acted. The stomach had been comparatively quiet, as she had only vomited twice or thrice during the night. There was considerable prostration, a quick, feeble pulse, and furred tongue. The tenderness over the abdomen had not increased, though the tympanitis had. I directed wine and beef-tea to be given in small quantities frequently, and an enema to be administered through O'Beirne's long tube, hot bran poultice over the abdomen, and a grain of the watery extract of opium, with three grains of calomel, to be given three times a day. The following morning (August 3rd) I found that she had had a restless night, great uneasiness in the bowels, and the countenance showed much distress; the bowels still unrelieved, and a great tendency to reject everything save the wine; pulse 130, feeble and wiry. I then myself introduced O'Beirne's tube its entire length with some difficulty, and threw up twenty ounces of tepid water, with an ounce of oil and half an ounce of spirit of turpentine mixed. In about an hour the lavement came away, and brought with it a large amount of feculent matter and scybalæ. To continue wine, beef-tea, opium, stupes, &c. The 4th, I found that the patient had slept pretty well, that the bowels had acted frequently, and that the more urgent symptoms were greatly relieved. On examining the wound, I observed that the integument and cellular tissue around it were in a sloughy condition, and that, from within the abdomen, there was a copious discharge of deep-coloured serum, mixed with oily matter and shreds of what seemed to be omentum. I ordered a poultice over the wound, and the same treatment as before to be continued, with the addition of four ounces of whisky daily. On the 5th, I found matters progressing satisfactorily, and indeed after that date she gradually improved, though she had occasional attacks of colicky pains with tympanitis. These attacks were always relieved by a mild aperient and carminative draught, and turpentine stupes and warm enemas. For two months from the date of the 6th of August, the wound continued to discharge great quantities of serum with seemingly disintegrated omental fat. Sometimes this discharge very much resembled feculent matter, but

without its odour, sometimes it resembled chopped-up yolk of egg, and occasionally that of the orange-coloured discharge that appears frequently around the wound in a limb with compound fracture. During this time the bowels continued to act per vias naturales, but often required to be stimulated by the draught I have alluded to, or by an enema. Without further prolixity, then, I may say that my patient continued under my care till the 30th ultimo; that the external wound gradually granulated and closed; that some serous discharge continued till about the 20th of October, when it gradually ceased; and that the patient was discharged at her own request on the 31st, hearty and well, a small point of the wound still remaining unhealed.

Remarks.—There are several points of interest in this case which every member will have noticed; to one or two of them, however, I shall refer more particularly. The first is the fact of the piece of gut that was found strangulated in the omentum, and which, if it had not been discovered and freed, would have likely produced a fatal termination to the case. It was not by chance that I was directed to its detection, but by search, as I had experience, through a post-mortem examination, of a case in which I had reduced a strangulated portion of omentum, as it seemed only, but within which and confined by a firm band, I found after death a very small fold of intestine still strangulated. Hence, I make it a point always to search carefully in such cases, whether a piece of intestine may not be held within the omentum that had been protruded.

The next point of interest is, the amount of subacute peritonitis that was present, and the great quantity and persistence of the discharge. I have no doubt that the intestine was not opened by ulceration, but that the discharge which resembled feculent matter was simply the product of the inflamed peritoneum, though probably the piece of omentum that had been strangulated was, in the first instance, disintegrated and cast off. The use of stimulants in such a case would formerly have been deemed unsafe; but their utility in that before us, nay, the absolute necessity for their administration, was most apparent, their action most satisfactory.

The administration of opium I found also of great service; while I may remark that the introduction of O'Beirne's long tube, and the injection of a large quantity of tepid water, with oil and turpentine, was followed by immediate and permanent relief to the most urgent symptom—namely, the obstinate constipation and the excessive intestinal tympanitis.

November 15th, 1862

Present, Drs. Ferguson (Chair), Browne, Patterson, Ferguson H. S., Beck, Gribbin, Reid J. S., Thompson H., Cuming, Pirrie, Johnston, Arnold, and Whitaker.

Moved by Dr. Patterson, seconded by Professor Reid and resolved, "That the transactions of the Society be offered in future to the Dublin Medical Press

for fortnightly publication".

Dr. Browne was requested to write to the Editor of the Press and make the necessary arrangements.

The President read a report of an extraordinary case of pemphigus.

Paper:¹ I should hope that the interest and importance, as well as the infrequency of occurrence of affections similar to the following case, will justify my bringing it before the Society as a simple fact. The generic name of pemphigus has been given to it, as it were, by the common consent of those who saw it earliest. Nor am I inclined to take exception to the name, though I am free to admit that I habitually regard our nomenclature of skin diseases as rather arbitrary. Its characters would, perhaps, justify our referring it to that nosological class rather than any other; but, as its history will sufficiently demonstrate, it differs in many essentials from the recorded descriptions, as well as portraits, of that class of affections, nor would its specific features admit it to be ranked as one of its described varieties. These were so well marked and peculiar as to suggest, and I think merit, the specific designation of "Gangrenosus." I am indebted to our House-Surgeon, Dr. David Moore, for the particulars of its history:—

James Graham, æt. 28, an auctioneer's clerk and porter, married, of temperate habits, was admitted into the Belfast General Hospital, October 15, 1862.

Eleven years ago had an attack of rheumatism, and has ever since been subject to occasional seizures of palpitation of the heart. Four months ago he suffered from pleuritis of the left side, and has since complained of pain in that side, general debility, and loss of appetite. For the past two months he has had a constant and severe cough, attended with frothy whitish expectoration, which became streaked with blood three weeks ago, when the fits of palpitation also increased in severity, and were accompanied with considerable pain, for which he consulted a medical practitioner, who told him that he laboured under organic disease of the heart, which would shortly prove fatal, ordering for him a combination of Dover's powder and uva ursi, with syrup of iodide of iron.

Ten days previous to his admission to hospital a peculiar skin-eruption made its appearance, not preceded by rigors, or any constitutional disturbance proceeding from it, so far as can be ascertained. On its appearance, however, the cardiac pain and palpitation were markedly mitigated in severity, and the cough and expectoration ceased. A few vesicles containing a clear serous fluid, very similar according to description, to those of pemphigus, showed first on the chin and face; for the first three days, few in number and distinct. Soon, however, the whole face became covered, the vesicles becoming confluent, and a similar eruption mak-

¹ [Dublin Medical Press, 1862, December 10, p573.]

ing its appearance on the dorsum of the hands, the rest of the body being perfectly free.

On admission, the face was much swollen and covered with a moist yellow crust, resembling in aspect boiled cauliflower; the eyes closed, and nostrils nearly so; the lips so tumid from the eruption as to necessitate the exhibition of fluid nutriment through an elastic catheter; the back of both hands covered with vesicles similar to those on the face in different stages of progress. At first the vesicles, filled with a clear fluid, gradually increased in size, becoming more opaque and pearly, then livid and burst, coalescing into each other, and covering the whole face with the yellow crust before referred to, from which a thin ichor exuded, presenting a very strong resemblance to the face of a patient in confluent variola about the ninth or tenth day of the eruption.

I may add, that the odour exhaled from the diseased surface was peculiarly offensive, indeed almost gangrenous. Pulse 105, weak, soft, and wanting volume; tongue moist, but could not be protruded; bowels regular; great general distress; in fact, the case presented a very formidable aspect, so much so, as to cause some of my colleagues, who saw it in consultation with me, to form an unfavourable prognosis. He states positively that he has not lately been working in any way with horses, dogs, fowl, or other animals, nor has he been engaged in teasing horse-hair, or come in contact with other animal matters; such inquiries being dictated by the strong suspicion that the phenomena presented in the case depended on the reception into the system of some animal poison. On this day the accompanying drawings of the appearances presented by the face and hands were made by Dr. Moore, and most faithfully do they portray their every peculiarity. I may remark that on referring to the delineations of pemphigus given by Cazenave, Rayer, and Bateman, none of them present even a family likeness to the features of the case of Graham. Wilson's portrait, which I lay before the Society, presents in some points a faint resemblance.

He was ordered, vini ℥xvj.

R. Acidi nitrici dil., acidi muriat. dil. aa. ℥ss. M.

Guttas, xx. 3tiis horis.

Linimentum aquæ calcis to be constantly smeared over the face and hands; beef-tea, milk, &c., to be freely administered, with an opiate at night.

16th: Pulse 95, improved in quality; face more swollen; eyes completely closed; bowels free; takes his wine and nourishment.

17th: Pulse 92; progressing favourably. Pergat.

19th: Pulse 100; swelling of face somewhat subsided, permitting the eyes to be partially opened, showing their conjunctivas highly injected; progressing favourably.

23rd: Pulse 88, fuller and firmer than hitherto. Ordered a chop; wine, ℥xvi. daily; swelling of face, lips, and eyelids much less, permitting the eyes to open

freely but not fully. However, the elastic catheter is still necessary for drinking purposes.

26th: Continues to improve; hands to be poulticed.

28th: Wine reduced to ℥x.; hands to be dressed with simple dressing; physical examination of the heart to-day gives all the signs of permanent patency of aortic valves.

November 1st: Doing well. Pergat.

4th: Dressings to be discontinued, as the hands are almost healed, but few crusts remaining; poultices to be applied to face, lips, and chin, to remove crusts; beef-tea to be discontinued; solid food; wine reduced to ℥vi.; warm bath every second day.

From this date he became Dr. Pirrie's patient. His convalescence has been steady, and I beg leave to introduce him to the members for their inspection.¹

Dr. Browne read case of amputation at shoulder joint with secondary hæmorrhage.

Paper:² Charles Stewart, aged 18 years, a mill-worker, was admitted into the Belfast General Hospital on the morning of the 10th of May last, having sustained, half an hour previously, a severe injury from having been caught in a carding-machine. On examination it was found that the left hand and arm were completely smashed up to within a short distance of the shoulder-joint; the humerus was broken through above the middle, the soft parts being greatly lacerated close up to the axilla, from which the torn ends of the nerves hung down some inches; the deltoid muscle was not extensively injured, though the integuments covering it and the scapula were furrowed deeply by the teeth of the card. But little hæmorrhage had occurred, though the little fellow was labouring under great depression from the nervous shock. Stimulants were given, and when some reaction had been established, chloroform was exhibited about half an hour after admission—the anæsthetic, I may remark, greatly assisting in giving a fillip to the circulation. In consultation with Professor Gordon, I determined to dissect out the axillary artery from the bruised and entangled mass and tie it before I proceeded to disarticulate the humerus, with the view of placing the ligature beyond the point at which it had been greatly put upon the stretch; having done so as high as possible, I made a good flap out of the deltoid muscle and integument, cleared away, as far as practicable, the torn soft parts which had formed the floor or base of the axilla, and then turned the head of the bone out of the glenoid cavity. Three additional arteries were ligatured; the parts, thoroughly cleaned, were put in apposition, and strips of wet lint, with a compress and bandage, were applied.

The patient was then removed to a warm bed, heat was supplied by means of the ordinary hot-water pans, and an opiate administered. The poor lad, I may

¹ [Later died and heart shown to the Society. See page 992.]

² [Dublin Medical Press, 1862, December 10, p574.]

observe, lost no blood in the operation, felt of course no pain during the procedure, and rallied very quickly after. At the evening visit I found that complete reaction had been established—too much, indeed; the pulse was full, 140 beats, the face flushed, and skin hot. Three grains of calomel, to be followed by a Seidlitz draught next morning, were ordered, and a saline mixture was directed to be given during the night. Next day I found that the patient had slept well, the bowels had been freely opened, and, on the whole, he was doing very well. On the 13th, I removed the dressings for the first time, and observed that part of the wound looked sloughy, without an attempt at union by first intention at any point; this, however, I expected, as in these cases where the soft parts have been lacerated and the integument put much upon the stretch, as usually happens in mill accidents, union by primary adhesion is exceptional; unless, indeed, the amputation shall have been made far above the parts that have been so stretched.

Up till the morning of the 18th, almost eight complete days after the accident, everything progressed favourably, when, at five o'clock a.m. on that day, secondary hemorrhage suddenly occurred. The house-surgeon and resident pupils were promptly by the patient, and firm pressure having been applied over the flap and directly on the subclavian artery, the bleeding was stopped. On my arrival at the hospital at six o'clock, I found the little fellow had lost about four ounces of blood, which had trickled slowly at first from under the dressings, and having been observed, the flow was checked before a great quantity was lost; still he was pallid and weak, with a shabby, quick pulse, though he was full of courage!

I carefully removed the dressings and pads that had been applied, and desired the pressure over the subclavian artery to be taken off; there was not, however, any return of the hæmorrhage, nor indeed any sign of it for the hour I remained by the bed-side. Being then satisfied that I should not further interfere with the wound, and hoping also that the bleeding came from some small vessel that had been overlooked at the time of the operation, I applied some fresh dressings, with a light pad and bandage, and left a resident pupil in charge. At two o'clock p.m., a smart return of the bleeding took place, which was restrained by pressure on the subclavian, and which was kept up till four o'clock p.m., when it was removed.

The blood lost on that occasion was estimated at some four ounces. At half-past five a fresh hæmorrhage returned with violence. On my arrival, a few minutes after, I saw the necessity for prompt interference, as the little lad was very pale and weak, with a very feeble, quick pulse. I proceeded, therefore, to open up the wound (the patient under chloroform), while Dr. Pirrie and the house-surgeon kept up pressure on the subclavian. After a considerable amount of search and dissec-

tion among the matted textures, I saw the point from which the bleeding came, evidently the axillary artery, and which threw out occasionally a great jet of blood when, by any movement of the patient, the pressure was relaxed for an instant. With some difficulty I seized the bleeding vessel, not being particular, indeed, to exclude the surrounding tissues, and passed a strong ligature around it, and having tied it, I found that the hæmorrhage was completely arrested. But, to give additional security, I applied a firm pledget of lint to the part after it had been saturated with a strong infusion of matico, and put on light water-dressings and a bandage. On consulting with my colleague, Dr. Murney, who had then arrived, it was deemed advisable to let matters rest, keeping a sharp lookout for any recurrence of the hæmorrhage, and should it return, being prepared to ligature the subclavian in the middle part of its course. Fortunately, however, everything progressed favourably, the ligature came away on the morning of the 26th of May, and the pledget of lint a few days later.

The wound granulated kindly, and healed up completely by the end of June, when the little lad was discharged. I should state that the medical treatment consisted in the exhibition of opium, muriated tincture of iron, with full allowance of wine and beef-tea. I cannot conclude without expressing my thanks to the House-Surgeon, Dr. David Moore, and the Resident-Pupils, Messrs. Joseph Mackenzie and W. A. Browne, for the unremitting care and unwearied attention bestowed upon this interesting case.

Dr. Johnston showed kidney from scarlatina patient and made some interesting remarks thereon.

A discussion ensued in which most of the members took part and Dr. Johnston was requested to introduce the subject for discussion at a future meeting.

22nd November, 1862

Present, Dr. Ferguson (Chair), Drs. McGee, Pirrie, M. McGee, H. S. Ferguson, Browne, H. Thompson, Arnold, Beck, Gribbin, Patterson, Cuming, H. MacCormac, and Whitaker. Also Dr. Saunders 14th Depot Battalion as a visitor.

The minutes of last meeting were read and confirmed.

Dr. Browne read a letter from Dr. Jacob of Dublin regarding the publication of the transactions of the Society and was requested to continue the correspondence and report to next meeting.

Drs. Little of Lurgan and McCrea (Belfast) were elected members of the Society.

Moved by Dr. M. McGee and seconded by Dr. Arnold "That the Council be instructed to purchase a microscope for the use of the Society to be placed in the rooms, 33 High Street, and that a sum not

exceeding £12 be debited from the funds for that purpose”.

Dr. Pirrie moved and Dr. Pirrie [sic] seconded the following amendment, “That the propriety of and possibility of procuring a microscope for the use of the members be referred to the Council for consideration and that they report thereon on this day fortnight”. Amendment carried.

Dr. McGee handed in following notice of motion “That no question shall be entertained by this Society of which due notice shall not have been previously given in the weekly circular, with the exception that on the final meeting in December, February and April any matter or question may be brought before the Society”.

Dr. Browne then brought forward a child 2 years old, who had sustained laceration of the perineum and other serious injuries by having been run over by a dray, and gave a very interesting history of the case.

Paper:¹ A. C., aged 2 years, was admitted into the Belfast General Hospital on the afternoon of the 30th of July last, having been run over by a horse and heavy “float” (ten hundred weight) a few minutes before. On examination, it was found that the wheel of the dray had passed over the upper part of the left thigh and obliquely across the pelvis. The integument of the thigh and abdomen was only slightly abraded; but there was extensive laceration of the perineum, the vagina and lower part of the rectum being laid into one to the extent of three-fourths of an inch. The pubis was separated at the symphysis, and the mucous membrane to the left of the orifice of the urethra was torn to the extent of nearly an inch. The closest examination could not detect any further lesion, and there was not certainly dislocation of either femur. The poor little child, as might be expected, was suffering from great pain and the shock of such a severe injury. Very little bleeding had occurred.

I ordered some wine-why to be administered, with two drops of the tincture of opium every three hours till quiet had been procured and reaction established. I also directed the pelvis and limbs to be rolled in flannels, wrung out of warm water. For some days the issue seemed very doubtful; but at the end of a week the little thing began to take its food pretty freely, and to give evidence that it would not likely succumb to the effects of the accident. During this time, I should remark, there was incontinence both of the urine and fæces. At the end of three weeks the parts around the left hip-joint became hot, tender, and swollen, and I then considered that an abscess was likely to form. After ten days, however, we had clear evidence that spontaneous dislocation at the left hip-joint had taken place, and I was then led to believe that the swelling I have just referred to arose from inflammation within the joint and con-

sequent effusion, and of course displacement of the head of the bone from its socket. The mother of the child, who had remained with it in hospital, about that time became anxious to return to her family, and at the close of five weeks from the date of injury she took her child home (3rd of September). From that date till yesterday I had not seen my little patient, and I now beg to draw the attention of the members to the child’s present condition. There is dislocation of left femur on dorsum of ilium; there is separation at the symphysis of the pubis to the extent of nearly an inch, as the middle finger laid lengthways between the separated portions enters easily with the relaxed integuments into the chasm; there is also complete laceration of the perineum with prolapsus ani, and a large hernia on the right side. The torn mucous membrane has healed up, and the child can now retain the urine quite well, but has not complete command over the sphincter ani.

In conclusion, I may remark that I have brought this case under the notice of the Society for the purpose of showing what an amount of injury even an infant may sustain without fatal results. Considering the patient’s tender years, I fear that little can be done immediately to relieve its deplorable condition. I intend, however, to apply a truss to the hernial protrusion, and after some time I may, perhaps, be able, by operative interference, to remedy the prolapsus ani; but of course we are all well aware that it is most difficult to adjust any appliance, or to perform successfully a plastic operation, such as this case would require, upon one so very young.

With regard to the hip-joint injury, we have no remedy there! I have no doubt but that, at the time of the accident, the bones entering into the composition of the acetabulum were partially separated, as they would easily be in infancy, inflammation and effusion followed, and the head of the femur was displaced, and thus, at the best, the poor little girl must remain a miserable object for life.

Dr. Browne read notes of two cases of penetrating wound of the knee joint.

Paper:¹ The first of these cases, Mr. President and Gentlemen, to which I shall direct your attention is that of a patient recently discharged at his own request from this hospital, and who, I regret to find, has not made his appearance here to-day.

S. T., aged 29 years, was admitted into the Belfast General Hospital on the 27th of last August for erysip-
elatous inflammation of the left leg and thigh, the result of a wound received on the 24th. It appeared that while working with a chisel he accidentally struck it into the thigh, the instrument penetrating to a considerable depth. The wound was situated about three and a-half inches above the patella, and on a line drawn directly

¹ [Dublin Medical Press, 1862, December 17, p600.]

¹ [Dublin Medical Press, 1862, December 17, p600.]

upwards from the superior and outer angle of that bone, thus probably touching, or rather penetrating, the extreme limit of the capsule of the knee-joint. For the first two days after the injury he did not think much of it; but on the 26th great pain in, with considerable swelling around, the knee came on.

On admission to hospital I found great inflammation, of an erysipelatous character, extending from mid-thigh to the ankle of left limb. There was also considerable effusion into the joint. The patient was likewise labouring under a great amount of febrile irritation, tongue dry and red, pulse quick and sharp. Hot stupes were directed to be constantly applied to the limb, and I ordered, after the bowels had been fully cleared out, a combination of tartarized antimony, calomel, and opium; with milk diet, and enforcement of perfect rest of the part. For several days the treatment to which I refer was kept up; but still the patient laboured under great pain of the affected joint and severe irritative fever. On the 4th of September there was a large discharge of synovial fluid from the wound, and the general inflammation of the limb had somewhat abated. As the system was slightly under the influence of mercury I lessened the dose of that drug, but continued the use of full opiates, and ordered for him a diaphoretic mixture. I also then ordered the entire inflamed parts to be painted daily with the strong tincture of iodine, and to be enveloped in a linseed-meal poultice. The discharge from the joint continued to be copious for some time. Occasionally this was simply coloured synovia; at other times it contained purulent fluid mixed with the synovia, and sometimes cholesterine-like matter was mingled with it. During that period the pain of the part continued to be very great upon the slightest motion, and the swelling of the leg was persistent. After the lapse of three weeks the discharge ceased, and I had every hope that the urgent symptoms had been subdued, when acute pain was once more felt in the joint just over the inner part of the head of the tibia; for this I ordered repeated local leeching, and the mercury, which had been discontinued, was directed to be given again. By the middle of October the attacks of inflammation had entirely ceased, the swelling of and around the joint had nearly disappeared, and under the use of the iodide of potassium internally, and the local application of strong tincture of iodine, with generous diet, the patient was brought to a state of satisfactory convalescence, and he was discharged, at his own request, on the 14th of November. He could then bear his weight upon the limb, and had passive motion without pain. Of course he was directed to be most careful of the limb. Perfect rest for some time was enjoined, and when any attempt at using the part was to be made, he was cautioned to desist the moment he felt the slightest pain. I may add that, under all the circumstances of the case, I consider that complete ankylosis of the joint would be for the

patient the safest result. If, however, the joint reacquired the power of flexion and extension, it certainly would be more satisfactory to those who have had the care of this very dangerous and interesting case.

Dr. Browne then introduced a boy who has sustained 2 wounds from a penknife, one in the abdomen, the other in the knee, and described the progress of the case.

Paper:¹ I am now about to show the Society a patient who has been in hospital for nine weeks in consequence of wounds received in a scuffle, but shall first read the notes I have taken of the nature and progress of the injuries:—

James Nelson, a healthy lad, aged 15 years, was brought to the Belfast General Hospital on the evening of the 21st of September of this year, having a short time previously been stabbed by a companion in a quarrel. On examining him I found, an inch and a-half anterior to the end of the eleventh rib, an incised wound, extending an inch and a-half in an oblique line towards the umbilicus. This wound was simply through the integument at its upper extremity, but at the centre and nearly to the lower end, it penetrated the cavity of the abdomen, permitting my finger to enter, and with which I touched the great curvature of the stomach. I found also a wound penetrating the right tibio-fibular articulation, and nearly an inch in extent. The patient did not seem to be suffering much pain from his injuries, nor was there any marked collapse, such as one would naturally expect under the circumstances. These wounds were carefully brought together by interrupted suture and adhesive plaster, supported by pads and bandage; of course I regarded the abdominal injury as of great danger.

I ordered an opiate at once, and directed a grain of opium with one grain and a-half of calomel to be given every four hours; low diet and perfect quiet were also strictly enjoined. Next day I found the young lad fully under the influence of opium; he was free from pain, and without tenderness of the abdomen on pressure, save at the point of lesion. On the 23rd the pills were discontinued, but an opiate was ordered to be given at night and morning. For four days he progressed most satisfactorily, and I did not interfere with the wounds. On the 5th day I removed the dressings, when I found that the wound in the abdominal wall had united by the first intention, but that over the knee had not, and its edges looked thickened and irritable, and on the 27th there was a slight discharge of synovial fluid from it, still the joint was not swollen. On the 29th, the lad felt so well, the abdominal wound being healed, that he was desirous of being permitted to rise for a little. That request I refused to sanction, because the knee seemed a little swollen and tender around the wound, which was

¹ [Dublin Medical Press, 1862, December 17, p601.]

looking rather unhealthy. That night he was seized with a sharp rigor, and acute inflammation was developed in the joint, and on the following morning I found him hot, flushed, and very feverish, with great effusion into the joint. Leeches and hot fomentations were immediately ordered, and lint, dipped in spirit lotion and covered with oiled silk, was directed wherewith to envelope the knee afterwards. I also prescribed the calomel as before, with half a grain of opium in each dose. Up till the 6th of October the synovia continued to flow freely from the joint, when it ceased for some days. During this time an unhealthy fungous-like granulation rose from the wound. Though the knee had been repeatedly leeches, and the medicines had been continued, the acute inflammation was not much subdued. On the 8th I stopped the calomel, and ordered instead of the spirit lotion a cataplasm of linseed-meal to be applied. Up till the 16th the patient did not improve; his appetite, which had been good, had failed; he became somewhat hectic, and the joint was still greatly enlarged, though the pain was not very severe. Occasionally, indeed, it became intense, when a full opiate usually gave early relief.

On the 16th I ordered him to take four grains of the citrate of iron and quinine three times a day, and I gave him improved diet. On the 18th a discharge of coloured synovia, mixed with purulent-like matter and flakes of lymph, took place, and from this the enlargement began to diminish, the pain ceased, and the lad improved in condition. The tonic was continued, the joint was painted over daily with the strong tincture of iodine, and spirit lotion was reapplied. From the 28th to the date of his discharge from hospital this day, a splint was applied so as to keep the knee extended and at rest, as the best I can hope for is a stiff joint. You will now perceive, on examination, that there is still enlargement of the joint, and apparent displacement of the relative position of the tibia and femur. Whether there is much change of structure within the joint I cannot say; but it is a hopeful sign that there is power of moving the part without the slightest pain. It is true that the amount of motion is very little, but that does not convey any jarring sensation to the touch, as if the internal structures were disorganized.

I intend to apply mercurial plaster for strapping the knee, and shall support the part with a bandage.

On the whole, I think I may remark that both of the cases I have brought forward are possessed of considerable practical interest; the latter especially, as it fully illustrates a fact now well known to surgeons, that a penetrating wound of the abdomen, though ever to be regarded as of a dangerous character, need not necessarily be followed by any untoward symptoms. I need scarcely refer to the treatment in the first instance, beyond stating that it was on the opium and not the calomel that I placed my hopes of warding off the peritonitis, the advent of which, for the first few days, I had

reasonable ground to dread.

The history of the progress and issue of the injury of the knee-joint in this case is also of great practical interest, as it shows the danger that is always to be apprehended from a penetrating wound of a joint, especially of the knee; for even, in this instance, the treatment pursued regarding the abdominal wound and the absolute rest, did ward off the very serious results that ensued upon a seemingly trifling wound, and which, in the first instance, was not supposed to have injured the main joint. I may here mention a very interesting case of injury of the knee-joint which I had under my care several years ago. By a direct blow in a fall from a height, a man, 57 years of age, sustained a compound comminuted fracture of the right patella. The joint was opened, so as to admit the finger, and under these circumstances grave doubts were entertained as to the expediency of endeavouring to save the limb. However, the parts were brought together, water-dressing applied, and the limb kept quiet in the straight position. Not one bad symptom supervened, beyond the escape of the synovia, which continued for a few days. In nine weeks the wound had healed up, and the man left the hospital fourteen weeks after the receipt of the injury with an excellent stiff joint, and which has remained firm and sound up till this time.

Dr. W. McCormac thought that the joint in the case exhibited was nearly disintegrated, from the lateral motion of the tibia upon the femur, showing that the lateral, and probably the crucial, ligaments had been partially destroyed.

Staff-Surgeon Saunders said that he thought a starch bandage around the knee and occasional walking would be better than rest and strapping—a mode of treatment he had adopted in a case which he mentioned, and with complete success, especially as regarded the general health of the patient.

Dr. McGee said there were two indications to be observed; first, to prevent inflammatory action; and, in the second place, to reduce the swelling and thickening around the joint; for the former, he thought that rest and quiet were indicated; for the latter, bandaging should be persevered in.

Dr. Whitaker considered that the case alluded to by Dr. Saunders differed materially from the case exhibited by Dr. Browne; the former was one of chronic disease; the latter, the result of direct injury, therefore requiring different treatment.

Dr. Browne briefly replied, reiterating his views relative to rest, mercurial strappings, and bandaging.

Note.—I have seen both of those cases to-day (Dec. 14th), and found that S. T. has a stiff joint, nearly quite ankylosed. The man can walk without pain, and, save a little uneasiness when pressure was made over the inner part of the head of the tibia, I could not detect anything wrong. The joint is of natural size, and the bones are in their proper relative position. He has kept

quiet, and has had the part well bandaged. The lad, J. Nelson, has no pain. The joint is still a little enlarged, but the deformity which existed has nearly disappeared. He can walk pretty well, and has considerable motion of the joint—semiflexion and nearly complete extension. His health is excellent also. He has been very careful, has observed quiet, and has worn mercurial strapping and a starch bandage round the joint since his discharge from hospital three weeks since.

November 29th, 1862

Present, Dr. Ferguson in the chair, Drs. Pirrie, Browne, Dill, Patterson, Michael McGee, Arnold, MacMahon, T. Reade, Cuming, Stewart, W. MacCormac, Whitaker, D. Moore. Visitor, Staff Surgeon Saunders, 14th Regiment, Dr. Eustace, Dublin.

The minutes of the previous meeting having been read and confirmed, Staff Surgeon Saunders read a paper on a case of urethral stricture when the passage presented two strictures, one of six years standing, the other of more recent date, in which Holt's dilator was used successfully and No.10 silver catheter being passed immediately after the operation.

In a short time the man had recovered very satisfactorily.

Paper:¹ A soldier of the 62nd Regt., aged 25, admitted into the 14th Depôt Battalion Hospital, May 16th, on account of two strictures, one of six years' duration, situated in the membranous portion of the urethra, the other of recent date, about two inches more forward. The man complained of difficulty in micturition. After a few days I was enabled, with great difficulty however, to pass No. 6 catheter into the bladder. On the 31st the dilator was introduced, the strictures split, and a No. 10 silver catheter immediately passed into the bladder, which has since been frequently done with perfect ease. On August 13th, two and a-half months after the operation, no trace of the second stricture could be detected.

This method of treatment, so ably advocated by Mr. Holt, has this great recommendation, that while the operation affords rapid, and, in most instances, permanent relief, with a fair prospect of ultimate recovery, it does not involve any risk to life, which cannot be said of the perineal section, as introduced by Mr. Syme. Then, as regards the old method, or that of gradual dilatation, it is not only slow but tedious, and oftentimes most unsatisfactory in its results.

Dr. Browne said that although Staff Surgeon Saunders' paper would shew the value of Holt's dilator in certain cases, he could not agree in the observations with regard to its comparative safety to Syme's perineal section, as Holt's dilator in cases calling for Syme's section was to his mind altogether inapplicable.

Dr. T. Reade considered the dilator would be ap-

plicable only in select cases when there was no disease of the bladder, or urethral inflammation, or where there was no rapid stricture from gonorrhœa; with latter cases the dilatation would incur local and constitutional risks.

He was adverse to other means than delicate handling and gradual dilatation of so tender a part and had never failed save in certain cases when Syme's section was alone applicable. He considered Staff Surgeon Saunders' case as one well suited for dilatation.

Dr. W. MacCormac wished to know if the No. 10 catheter introduced after the operation was left in the urethra or withdrawn immediately.

Mr. Saunders replied that the catheter was withdrawn at once when the water was drawn off, and considered its retention in the passage could do more harm than good. The mucous membrane being uninjured there was no danger of infiltration of urine, and by the sudden relief of the stricture a great advantage was obtained over the gradual mode of dilatation which was not without risk from its frequent repetition even in the most careful hands, and there was also the risk of complete retention with much irritability of the passage after a debouch with an increased liability of false passage. The man was kept ...

Dr. Eustace remarked that Drs. Smylie and MacNamara had used the dilator very successfully in many cases of stricture in Dublin.

Dr. Pirrie showed the morbid parts of a case of stricture of the œsophagus. The stricture extended two and a half inches from the cardiac orifice of the stomach, was two inches in length, and consisted of a deposit of hard cancer ulcerated at the upper part of its mucous surface to the extent of half an inch all round. The passage was narrowed to such a degree as not to permit the passage of a No. 5 elastic catheter. The œsophagus immediately above the stricture was but slightly dilated, no well-marked pouch being formed. During life there was no dyspnoea or stridulous breathing. The recent duration of the symptoms and suffering in so close a stricture were peculiar in the case. She had only suffered pain for 3 months past, and from difficulty of swallowing still more recently. About three ounces of fluid were retained for about ten minutes at a time after swallowing, and were then returned by the mouth.

Although no tumour could be detected through the abdominal parietes Dr. Pirrie thought the seat of stricture was at the cardiac orifice and that the fluid was retained in a pouch of the œsophagus. There was no dyspnoea or stridulous breathing during life.

Paper:¹ The patient, a female, æt. 52, had been admitted into the Belfast General Hospital a few days previously, supposed to be labouring under organic disease of the stomach. She was exceedingly weak and

¹ [Dublin Medical Press, 1862, December 31, p650.]

¹ [Dublin Medical Press, 1862, December 31, p650.]

very much emaciated, and had all the aspect of a patient suffering under malignant disease. She said that she had been only three months ill, that her illness commenced with difficulty of swallowing, which gradually increased, accompanied with a dull pain behind the lower part of the sternum.

On admission, notwithstanding her great emaciation, the most careful examination could not detect any enlargement or hardness about either extremity of the stomach, or indeed about any part of the abdominal viscera. She could swallow nothing but fluids, and of these (beef-tea, wine, &c.), she would take a very small quantity at a time, about half a wineglassful. This she would retain for about ten minutes, and then almost the entire quantity swallowed would be returned by an effort of vomiting, but without any sickness.

Dr. Pirrie diagnosed the probable existence of malignant disease of the cardiac orifice of the stomach, with dilatation of the œsophagus above the orifice. She sank rapidly, and died a few days after her admission into hospital. On examination twenty-four hours after death, the stomach (including both orifices) was found perfectly healthy but very much contracted on itself; but about one inch above the cardiac extremity, there was a dense thickening of the coats of the œsophagus, extending upwards more than an inch, and encroaching upon the calibre of the tube, so as almost entirely to obliterate the passage. Indeed, even after the œsophagus was laid open, the smallest bougie could not be passed through the indurated mass. The lining membrane was extensively ulcerated at, and immediately above, the seat of obstruction. Microscopic examination revealed the existence of the usual characteristics of malignant deposit in the seat of the disease.

Dr. MacMahon had seen the woman casually several times since the commencement of her illness. About four months ago she was in robust health, plump, and was able to swallow freely, it was only about four weeks since the power of swallowing became very much obstructed, when the emaciation became rapid and extreme.

Dr. T. Reade had a case of stricture of œsophagus, doubtless organic, which ran a tedious course of 18 months. Could swallow fluids, lived chiefly on milk. Sank at the last from an extrinsic cause. No P.M.

Staff Surgeon Saunders referred to a case under his care who vomited everything he took. When dying of inanition Dr. Saunders fed him per anum under which treatment he rallied living for some months without taking food by the mouth for at least a considerable portion of the time.

Dr. Reade had found much benefit from injections per anum in such cases.

Dr. Arnold asked Dr. Pirrie if he thought any fluid passed through to the stomach at the later period of the case. Dr. Dill remarked that as far as he knew all

cases of œsophageal scirrhus died of inanition and that any artificial means of feeding them would keep them alive.

Dr. Ferguson differed from Dr. Dill's view and thought that the presence of such an amount of disease in the œsophagus would produce constitutional effects independent of the stomach.

Dr. Pirrie suggested that the dilated pouch of the œsophagus might offer an absorbent surface for food as well as the rectum.

Dr. Cuming stated there could be no doubt that the nutrient enemata disappeared from the bowels, and the inference was manifest.

The Society then considered the question of the presence in the Society's reading rooms of persons who were not members. Resolved, That the Secretary be requested to communicate with Dr. Corry, and request him not to lend his key of the rooms to any person, not a member of the Society.

December 6th

Present, the President in the chair, Drs. Patterson, H. Ferguson, Browne, Beck, W. MacCormac, Dill, Cuming, Stewart, Brice Smyth, Arnold, McCrea, Gribbin, Michael McGee, MacMahon, Corry, D. Moore.

The minutes of the previous meeting having been read and confirmed, two medical gentleman were proposed as members of the Society viz Surgeon McCourt of Belfast (proposed by Dr. Whitaker, seconded by Dr. D. Moore), Dr. McWilliam of Belfast (proposed by Dr. Corry, seconded by Dr. Beck).

December 13th, 1862

Present, the President in the chair, Drs. Patterson, McGee, McCleery, T. Reade, McCrea, Michael McGee, Corry, Beck, H. Ferguson, Stewart, Moore, Dill, Pirrie, W. MacCormac, Murray, McWilliam, D. Moore.

The minutes of the previous meeting having been read and confirmed, a ballot was taken when Surgeon McCourt and Dr. McWilliam of Belfast were elected members of the Society.

Dr. John Moore, Glenarm, was proposed by Dr. Patterson, seconded by Dr. Ferguson, as a member of the Society.

Dr. Moore shewed a specimen of gangrene of the leg from injury, in which amputation had been performed in the middle of the thigh.

The patient a man of over 60 years of age was run over by a car in the street in front of the hospital. He was immediately brought in, when the popliteal space was found to be distended with blood effused from a ruptured popliteal artery. The tumour being very tense, firm, and modulated, occupying and distending the popliteal space. No pulsation could be discovered in the tumour, no bruit detected, no pulsation in the vessels of the leg below the injured point.

Gentle warmth was applied to the limb, bandaged

with cotton wool, and the tumour increasing and extending up the thigh on its posterior aspect, Ceartes compressor was applied to the femoral artery and pressure kept up steadily for three to four days. The swelling gradually beginning to subside the compressor was removed. Gangrene of the foot now began to show itself, extended up the leg, the line of demarcation passing just below the knee. Amputation was performed in the middle of the thigh as the effused blood had burrowed up even beyond that point among the muscles on the posterior aspect, giving a great liability to protracted and unhealthy suppuration or even sloughing of the flap formed at that part.

An anterior and a posterior flap were formed of skin alone, retracted the muscles then divided down to the bone, which was sawed through as high as possible in the face of the stump. One vessel only was tied, another with a patent mouth but from which no blood issued was also tied. The loss of blood was very trifling. The man doing well since. The artery in the amputated part of the limb on being examined shewed no signs of atheromatous degeneration.

Dr. Moore showed a part of the small and large intestine of a woman in whom a very extensive prolapsus of the colon had occurred. The mother of 14 children, 45 years of age, habitually constipated, for seven years past subject to occasional attacks of piles protruding to the size of a walnut unattended with any bleeding.

On pressing at stool having been constipated for four days, a sudden prolapsus occurred projecting externally with much pain in abdomen and prostration. On the evening of the next day she was admitted to hospital when on examination per vaginum that outlet was found free but on examination of the rectum it was found distended with a mass which projected from it turning forwards and upwards to the front of the pubis, twenty one inches in length of a deep chocolate colour, inflamed, with livid dry patches on its outer side consisting of prolapsed colon.

There was much depression of strength, pulse almost imperceptible, abdominal pain, hiccups, nausea.

General warmth applied, oiled lint to prolapsus which was not handled but kept quiet. Ordered wine and opium 2 grains with 3 grains quinine every second or third hour. She improved, strength increased, abdominal pain became less, when she was fully under the influence of opium in which state she was kept.

For eight days there was no movement in the bowels but at the expiration of that time purging set in which was checked for a time by the exhibition of [L?]. Kuro, Catechu and opii but which recurred, became persistent and finally everything swallowed was passed per annum very shortly after. She died 15 days after the admission. The part prolapsed extern-

ally sloughed away being completely separated about ten days after admission after which portions of shreds of broken down membrane came away from the anterior of the intestine with the stools up to two days before death.

December 20th

Present, the President in the chair, Drs. Pirrie, Cumming, Dill, Patterson, Browne, Beck, W. MacCormac, McCrea, Michael McGee, Gribbin, McCourt, Whitaker, D. Moore.

The minutes of the previous meeting having been read and confirmed, Dr. John Moore of Glenarm was elected a member of the Society.

P.M. (Dr. Moore's case continued). On opening the abdomen the cæcum, ascending, transverse and descending colon with the large omentum were found absent. Small intestine seemed dragged somewhat to left side, right side of the abdominal cavity being scantily furnished. Midway between umbilicus and anterior superior spine of ileum (left) the termination of the small intestine was firmly adherent to, and firmly consolidated with the parietal peritoneum for a space of an inch and a half in length, and an inch in breadth, the long diameter vertical.

The small intestine ended at this point and immediately below it in the commencement of the large the invagination was found. Above it for the space of two feet the ileum was deeply inflamed. The part nearest the attachment being filled with clotted extravasated blood, and the coats having, at points here and there, a tendency to break down under manipulation.

Below it, the large intestine for the space of a foot and a half was also much inflamed, its coats having at points the same tendency to break down when handled.

The invagination protruded in a nipple-like form of an inch and a half in length into the upper part of the remaining large intestine, all the prolapsed parts below its inferior margin having been cast off as a slough. The coats of the large intestine surrounding the nipple and those forming its under surface were tolerably firm and less effected by the inflammatory process than other points of it more remote from the seat of stricture, whilst the coats of the small intestine lining the passage through the nipple-like projection were softened by inflammation and ready to break down.

The passage from the ileum through the invagination into the large intestine lay not in the median line but more towards the side of attachment of mesentery to bowel, the tip of the nipple on that side being shorter than the other which projected below it, and curved slightly to that side.

Dr. Cumming thought it important to decide accurately the time of accession of first inflammatory symptoms in the invaginated part consequent on its

stricture.

This could be ascertained with some precision from the history of the case which showed the abdominal pain only commenced when the prolapsed part made its appearance externally, so that the inflammation which resulted in the casting off the prolapsed part only set in after this external tumour appeared. The fact of the tumour turning forwards with a bend or in an elbow-like form would seem to point to the fact that a greater length of intestine might be extended than even that occurring in this case.

Dr. Beck had seen the case on the evening of the day on which the prolapse appeared, and considered it presented a darker aspect and more inclined to gangrene, that would be likely to occur in so short a time. He thought it likely that the invagination had occurred sometime previously, but that the tumour had not made its appearance externally that morning.

Dr. McCrea thought that from the nature of the peritoneal attachment of the large intestine the process of prolapse to such an extent must have been a very gradual one, and that the invagination had occurred and was gradually increasing in extent sometime before its external appearance.

Dr. Pirrie considered it most probable that the intussusception had been sudden in occurrence and had taken place to its full extent at the time, and that there were no symptoms of any previous invagination connected with the history of the case.

Dr. Cuming thought it doubtful that invagination to any extent could occur without giving rise to serious symptoms, with much interference to the functions of the intestine, and to the process of digestion.

Dr. Pirrie exhibited a specimen of cancer of penis in which amputation of the penis had been performed about half an inch from the pubis. Two ligatures were applied. After a time there was slight hæmorrhage which did not return. The inguinal glands were enlarged probably in consequence of the irritation produced by the growth and consequent retention of urine. He considered this case nearly analogous to that of stricture of the œsophagus he had lately shewn the Society.

In both cases there was the same dense fibrous tissue forming the bases of the stricture, in both the same rapidity of growth, and almost complete occlusion of the canal. In the case of stricture of the œsophagus the smallest size of bougie could not be passed from before backwards even when the morbid parts were removed from the body, although it readily passed from behind forwards. In the present case a fine silver probe could not be passed from before backwards through the urethral stricture. The ulceration was also analogous in this case to that present at the upper part of the œsophageal stricture.

Paper:¹ *The patient had, till recently, been a hale and healthy man, always living in the country, and engaged in agricultural pursuits. Within the last year or so has had one or two attacks of retention of urine, occurring after exposure to cold, and a too liberal use of alcoholic stimulants (he is usually very abstemious); these attacks were evidently connected with some enlargement of the prostate. Not till some eight weeks only before the operation did he complain of any pain or uneasiness in the penis. What first attracted his attention was difficulty in passing water, followed by swelling of prepuce and glans, and afterwards by an offensive dark-coloured discharge. The difficulty in micturition gradually increased, till at last he became almost worn out with the almost constant efforts, night and day, to pass water. Any attempt to pass a catheter was followed by very copious hæmorrhage, which also sometimes occurred spontaneously. On the 25th October last he was first seen by Dr. Murney and myself. The penis was swollen and œdematous, with a hard base extending an inch and a-half backwards from the glans; prepuce thickened, and adherent to glans. Entrance for the smallest instrument into the urethra could not be obtained, even after the prepuce was slit open. Recognizing the malignant nature of the disease, amputation was recommended, and being approved of, was then and there performed by Dr. Murney in the usual manner. Notwithstanding the enlargement of some glands in left groin, the patient has recovered well. Dr. Pirrie directed attention to the great similarity existing between the present specimen and one of malignant stricture of œsophagus, which he recently exhibited to the Society, particularly the microscopic character and rapidity of formation in both diseased structures.*

Dr. Michael McGee had a patient sometime ago affected in like manner in whom amputation of the penis was performed. There was much hæmorrhage.

Dr. Browne had also a similar case, but without any hæmorrhage. He had united the mucous membrane of the urethra to the skin of the penis at the line of incision to prevent contraction of the canal. He thought the operation justifiable even with considerable enlargement of the inguinal glands.

Dr. William MacCormac considered the Écraseur a useful instrument in such cases. The urethra first should be dissected from the corpora cavernosa with the knife and then the Écraseur applied.

Dr. McCrea made some remarks to the Society touching the so-called "Sacramental wine" of a certain Mr. Lees Ph.D., a sample of which Dr. McCrea had obtained and subjected to analysis. He found it contained ten percent of alcohol with some foreign colouring matter and was to all intents and purposes "A Bad Claret".

Ulster Medical Society
Session 1862–1863
President John Creery Ferguson

Resolved That a Special Meeting of the Society be summoned to take place in the Rooms on next Saturday, 27th inst. at 3 o'clock p.m. to take into consideration the subject of publication of the discussions of the Society.

J. Creery Ferguson, President

**Special Meeting
December 27, 1862**

Summoned in accordance with resolution passed on 20th inst. "To take into consideration the subject of the publication of the discussions of the Society".

Present, Drs. Ferguson (President, in the chair), Cuming, Ferguson H. S., Moore, James, Smyth Brice, Patterson, Moore David, McGee Michael, Arnold, Browne, Dill, Reade Thomas, MacCormac William, Gribbin, MacWilliams, McCourt and Whitaker.

Dr. Browne having stated object of meeting and made some remarks on the history of the subject moved and Dr. Michael McGee seconded the following resolution "That our Secretaries be requested to continue their reports of the discussions at the weekly meetings of the Society with a view of having these reports published in conjunction with the papers that may be brought forward during the session".

An animated discussion having ensued. Dr. Dill moved and Dr. Moore seconded the following amendment,

"That the publications of the transactions in connection with the Ulster Medical Society, be confined to the read or spoken papers, and that the discussions thereon be not published". Amendment put from the chair and lost by the casting vote of the President. Original motion then put and carried in a similar manner.

Dr. Patterson then suggested that as the members seemed so equally divided in opinion, it would be better to allow the reports to be continued as usual during this session, and that previously to the commencement of the next, the matter could be fully discussed and some satisfactory arrangement entered into.

This suggestion not having been entertained by the Meeting, Dr. W. MacCormac moved and Dr. Patterson seconded the following resolution,

"That a Committee of publication be appointed consisting either of the Council or a portion of the Council for the purpose of reviewing discussions held on papers or communications made to the Society before issuing them to the profession in any form". Carried unanimously.

Dr. Reade gave notice of the following motion "That any Member of the Society entrusting his key to anyone not a member shall pay a fine equivalent to one year's subscription".

J. Creery Ferguson, President

January 3rd, 1863

Present, Drs. Ferguson (chair), Cuming, Patterson, William McGee, McCourt, Gribbin, Smyth, T. Reade, Beck, MacWilliams, Pirrie, Moore, W. MacCormac, Stewart, Saunders, Murray, and Whitaker.

The minutes of last meeting were read and confirmed. Payment was ordered for £10.7.8 being amount due for rent, gas, coals, Boy, postage etc.

Dr. W. MacCormac moved and Dr. Patterson seconded "That the Council be requested to take action on resolution of December 27th and that the matter be left in their hands". Carried unanimously.

Dr. McGee (W.) moved and Dr. Pirrie seconded "That no question shall be entertained by this Society of which due notice shall not have previously been given in the meeting circular, with the exception that on the first meeting in December, February and April, any matter or question may be brought before the Society".

Dr. Beck objected and thought that notice should always be given. He moved the following amendment, which was seconded by Dr. Stewart, "That no question shall be entertained by this Society of which due notice shall not have been previously given in the usual printed circular". Amendment carried.

Dr. Reade moved and Dr. Moore seconded "That any Member of the Society entrusting his key to anyone not a member shall pay a fine equivalent to one year's subscription".

Dr. William MacCormac then read a paper on varicocele, in which he entered fully into the causes, effects, and mode of treatment of same. He then detailed the history of a case which he had recently treated on the radical cure plan, with perfect success; and concluded a very interesting paper by stating the difficulties to be met with and the dangers to be avoided in pursuing that treatment.

Paper:¹ *The term varicocele is confined by usage to enlargement of the veins of the spermatic cord, though etymologically the word has a much wider significance. It is not a very uncommon disease; but whether, from its small extent, the little inconvenience it occasions, or its, in some instances, temporary nature, it is not always recognized. The left side is much more frequently affected than the right. Out of 120 cases operated on by Bresalet, only once did the varix occur on the right side. Post met with the malady on both sides but once. Vidal insists to such a degree on its greater prevalence on the left side, that, according to him, the existence of varicocele on the right side would imply transposition of the circulatory organs, which, of course, is a great exaggeration. I myself have known two cases of varicocele occurring on the right side, one of them the subject of the present remarks, without any malposition of the heart existing in either.*

¹ [Dublin Medical Press, 1863, January 28, p85.]

Many circumstances are alleged as inducing the greater liability of one side over the other. A similar predominance of the left side likewise subsists, it is interesting to note, in ovarian varicocele. Morgagni and Sir Astley Cooper account for this by the anatomical peculiarity of the termination of the spermatic veins, the left running into the emulgent vein at right angles to the current of blood in that vessel, the right entering directly into the inferior curve, in a direction almost parallel with the current in that trunk. There are valves, no doubt, in the larger spermatic veins, but when these become morbidly enlarged the valves themselves must cease to act. J. L. Petit has laid great stress on the fact that the left spermatic vein passes under the sigmoid flexure of the colon, and is, therefore, exposed to the pressure of the intestinal contents. Hence the alleged influence of habitual constipation in the production of varicocele. The usually greater length of the column of blood, on the left side, from the left testis, hanging lower than the other, and also the generally greater size of the left organ, are causes that have been cited. The proximate causes, inducing the disease, are often obscure. Venereal abuse, violent exercise, obesity, hernia, and many others, have all been alleged.

Varicocele is essentially an affection of early adult life. It most frequently occurs at from 15 to 25 years of age, rarely later, although Malgaigne mentions some cases as happening after that age. The size of the tumour is variable, and not in proportion to the amount of suffering induced. A varicocele no bigger than a filbert may occasion much constitutional disturbance, while a tumour very much larger may be attended with little inconvenience. Landouzy has seen the scrotal veins equal the femoral in size, while the tumour, as large as the foetal head, descended to the middle of the thigh. According to Nélaton the disease is confined to early and middle life, and dependent, he believes, in a large degree, on the sexual energy and excitement of that period. He considers it to be an affection of no great seriousness, and states that it has a tendency towards spontaneous cure in advanced life. Other authorities look upon it, and I think with truth, as of greater moment, ascribing to it atrophy of the testis, with considerable pain, mental depression, and general debility.

I do not propose to give any account of the various methods of treating varicocele. They have been numerous, from simple support of the parts to the use of the actual cautery, the ligature of the spermatic artery, the extirpation of the venous mass, and finally castration. I shall, therefore, proceed to narrate briefly the particulars of a case, sufficiently interesting, as I conceive, to engage attention.

Mr. M_ a young gentleman, aged 24, occupied at office work, of a lymphatic temperament, general health good, habits temperate, consulted me some time since for a considerable varicocele of the left side, and

as I afterwards, on closer examination, discovered, for a very appreciable enlargement of the veins on the right side. He was unaware of any cause, and did not know the time of its first appearance. He had noticed the varix casually, he said, while taking a warm-bath some months previously. The venous tumour was as large as a hen's egg, descending to, and partially enveloping, the testis. The scrotum was flaccid, while the testis, notably smaller than on the right side, hung fully an inch lower. The veins, much enlarged and increased in number, could be readily distinguished through the thinned integuments, imparting the peculiarly disagreeable sensation of a bag of earthworms.

Mr. M_ complained of dull, dragging pain in the testis and groin, also of pain in the back. These symptoms were much aggravated in the evening, and after unusual effort. He further complained of a change for the worse in his sensations. He was indisposed to take any active exercise, such as walking, reading, gymnastics, in all which he had been previously a proficient. Even moderate effort was productive of much languor and depression. Mr. M. was therefore, as might be supposed, extremely solicitous to submit to any means calculated to rid him of what he justly considered the source of his ill-health.

I determined, in the first instance, to try the effect of palliative treatment, and with that view, during more than three-months, administered the tincture of the perchloride of iron, coupled with cold douches to the part, and the application, during the day, of a well-adjusted suspensory bandage. This treatment improved the general health of the patient, but afforded him very partial relief.

Under these circumstances, the patient being very anxious to be cured, and the case being of sufficient urgency, I thought it right to attempt a radical cure. But first, I explained the possible dangers of the operation, the chance of atrophy of the testis, and the risks to life from phlebitis and purulent absorption.

The mode of operation I selected, and which I shall presently describe, is simple in character. I possessed the valuable assistance of my friend Dr. H. Burden. It was first initiated by Davat and Franc, and is the one recommended by Mr. Curling, as improved on by him, and described in the second edition of his work on "Diseases of the Testis." This method possesses many advantages over that of subcutaneous ligature, originated by Gagnebé, and adopted by Velpeau. There is much less risk of phlebitis, and the consequent evils, while it secures more perfect contraction of the scrotum and veins, and is, moreover, less tedious and less severe.

The operation was performed in a warm room, and the patient was made to walk about for some time previously, in order to render the veins as turgid as possible. The patient also stood during the insertion of the needles.

I employed a narrow-bladed sharp-pointed bistoury, a

thread of strong silk, well waxed, and a couple of needles, about $2\frac{1}{2}$ inches in length, of soft steel, with hardened points.

The first and most important step in the operation was to isolate properly the spermatic artery and vas deferens from the bundle of veins to be obliterated. This I did by grasping the veins, included in a fold of skin, with the fingers and thumb of the right hand, about an inch or an inch and a-half below the external ring. With the right hand the spermatic duct was readily distinguished, as a hard, round cord, very painful when pressed upon, as also the spermatic artery which accompanies it, and which can generally be felt pulsating through the integuments. These parts having been carefully separated were held aside. It is of great assistance, in making this division of structures, to compare the affected with the sound side, and the importance of this preliminary step in the operation cannot, I conceive, be too much insisted upon. If, for example, the entire plexus of veins be taken up, and no channel for the return of blood left, the testis will be apt to waste. And, again, if the spermatic artery and vas deferens be not left intact, atrophy of the gland is the almost certain consequence. This difficulty, however, being overcome the rest of the operation was easy enough. One needle was passed through the fold of scrotum, held in the fingers, from side to side, so as to include the plexus of veins to be occluded between itself and the skin. This needle is to be introduced at the point before indicated, an inch or an inch and a-half below the external ring. The other needle was similarly introduced about eight lines lower down, including, of course, the same veins. Here it was comparatively easy, from the upper needle being first introduced, and from the greater natural separation of the parts. A thread of silk was now wound around the ends of each needle, in a figure-of-eight, with sufficient firmness to occlude the veins perfectly, without at the same time strangulating the skin. The bistoury was then introduced underneath the veins, and between the two needles, and the plexus divided, cutting outwards. Only a drop or two of blood exuded, water dressing was applied, and the patient placed in bed. The operation, as thus described, was performed on April 29th. Quiet was enjoined, and an opiate given at bedtime. On the following morning I found Mr. M. had scarcely slept, owing to pain felt in the testis and groin, caused, doubtless, by pressure on some nervous filaments included by the needles.

On May 1st, all pain had subsided, save slight uneasiness; had slept well during the night; was free from anxiety of every kind, while a large mass of effused lymph could be felt around the ends of the divided veins.

On May 2nd, sixty hours after their introduction, I removed the needles. The lymph occupied the site of operation, while the veins engaged could be felt above and below filled with coagulum. Perfect rest was now

insisted upon, and a full opiate administered to restrain, for a few days, the action of the bowels, which had been previously well cleared out by saline purgatives. On the following day, and subsequently, the patient's condition was, in every respect, satisfactory. I need not enter into much further details. On the seventh day after the operation Mr. M. was able to rise, the parts being supported by an accurately fitting suspensory bandage. In about three weeks almost complete contraction of the scrotum had taken place, the effused lymph was, to a great extent, absorbed, while the diseased veins had become transformed into a cord. In short, the patient was cured, and it is to be hoped permanently, which result the record of former cases gives every reason to expect. Mr. M. visited me about six months subsequently; no remaining evidence of the former disease existed, save a small lump of hardened tissue at the site of insertion of the needles, and a thin cord representing the obliterated veins. The veins on the right side were likewise somewhat diminished in size. He had gained a good deal in weight, and his health, strength, and spirits, were better than he had known them for years.

Dr. T. Reade expressed his complete concurrence with the views put forward by Dr. William MacCormac as to the nature and treatment of varicocele. He had frequently met the disease but never had seen it existing on the right side.

Dr. Patterson recollected some 20 years ago having seen a case occurring in a boy 9 years of age, in whom the ordinary treatments with iodine painting, cold applications and suspensory bandage was useless. A firm plaited flannel bandage was applied and the boy got rapidly better. He thought that in such cases pressure was the only treatment likely to be attended with success.

Dr. Beck thought that ordinary palliative treatment was useless and that it was necessary to have resort to the radical method to ensure a permanent cure.

Mr. Saunders (Staff Surgeon 14th Depot Battalion) observed the disease very often during the examination of recruits, and always on the left side. He esteemed that a sufficient cause for rejection, especially when occurring in those intending to enter the cavalry. He found that variations in temperature causing contraction or relaxation of the scrotum interfered considerably with diagnosis.

Dr. Pirrie thought that the more frequent occurrence of varicocele on the left side was sufficiently explained by the pressure of the sigmoid flexure of the colon on the left spermatic vein. Varicose veins, he stated, occurred more frequently in the left than in the right leg.

The President called the attention of the members to the effect which varicocele would have when present in persons presenting themselves for life

insurance.

Dr. Pirrie would not reject for varicocele, but thought it evinced deficient power of circulation and general delicacy of constitution. He therefore would not consider the subject of a varicocele as a first class life.

Dr. Reade considered that in cases where the varicocele was not large, or produced uneasiness, or where there was not much or severe work to be undergone by the person, he would consider that the disease, per se, would not constitute a sufficient objection to returning the person as a first class life.

Dr. McGee (William) thought that in any case of varicocele the person affected therewith should not be considered as a first class life, and that in cases where the varicocele was so extensive as to require operation, he would reject the person altogether.

Dr. W. MacCormac replied that as varicocele was found to have no relation with varices in other parts of the body, and was in many instances a merely local disease, depending on local causes, it did not, of necessity imply general weakness, or want of tone in the constitution. He, therefore, thought that when varicocele did not produce any pain or incontinence, or interfere with the patient's daily avocations, it was not to be considered a ground for rejection in life assurance; the more so as the disease has in many cases a tendency to spontaneous cure.

J. Creery Ferguson, President

January 10th, 1863

Present, Drs. Ferguson (President, in the chair), Patterson, Ferguson H. S., McCrea, Cuming, MacCormac William, McGee Michael, Reade Thomas, Dill, Gribbin, Beck, and Whitaker.

The minutes of last meeting were read and confirmed. Dr. Beck read the notes of a case of tumour occurring on the labium mistaken for venereal affection and stated that the woman with whom the affection occurred was about 50 years of age, mother of a large family and that the tumour had been gradually increasing in size for some months. That previously to his examination of it, it had been seen by another member of the profession who had pronounced it to be of venereal origin, that he was of the same opinion until he examined it closely, when he found that the base was moveable and that he could squeeze some matter through its ulcerated apex. He cut down upon it and with a slight pressure removed the mass which consisted of the ordinary sebaceous secretion thickened and waxy. Dr. Beck then referred to the difficulty of diagnosis in some cases of this kind.

The President thought that in such cases, great care should be exercised and that no statement as to the nature of disease should be made unless the diagnosis had been previously well made only.

Dr. W. MacCormac thought the mistake was one

which might readily be made on a superficial examination, as the tumour referred to presented some of the characters of an Hunterian chancre. He thought, however, that its situation ought to have suggested caution as chancres of that kind are comparatively rare on the female genitals and their diagnosis proportionately difficult.

Dr. Moore brought forward the case of a little girl who had met with an injury in a mill. The thumb had been cut across, the bone severed about half an inch beyond the metacarpal phalangeal articulation, as if with a bone forceps, the soft parts having been also cut through.

The bone projected half an inch beyond the soft parts which had been torn. On examination Dr. Moore thought that the best course was to remove the metacarpal bone of the thumb at its carpal articulation and bring the soft parts together which he accordingly did, leaving a portion of the fleshy part of the ball of the thumb which could only be slightly approximated, as a covering.

Dr. Moore also brought forward a case of tumour on the upper eyelid, projecting into socket on outer side of the orbit, in which he operated, and removed it. He found the sack so thin and delicate that not withstanding the greatest care, it was ruptured, and required some troublesome dissection to remove it without leaving any of it adherent. Dr. Moore then made some remarks on the general principles to be observed in such cases and stated that particular care must be observed lest any of the tumour remain, as when such is the case fungoid growth almost invariably spring there from.

Dr. Beck would wish to know why Dr. Moore thought it necessary to remove the metacarpal bone in the former case. He had seen a considerable number of mill accidents in which injuries even greater than that related by Dr. Moore had been sustained, and yet no operation was required and the parts healed in a short time and left the parts injured in a surprisingly useful condition. He, Dr. Beck, thought in injuries of the hands or face, where the parts were so largely supplied with blood vessels, that an effort should, in almost every case, be made to retain the parts so injured and give the patient a chance of preserving them.

Dr. W. MacCormac said that very often the soft parts are more injured than would appear on a cursory external examination.

The President remarked that he was quite sure that Dr. Moore would be glad of this discussion, as it would give him an opportunity of satisfying the members present as to his reasons for the line of treatment he pursued; he (the President) had no doubt that Dr. Moore's explanation would be found most satisfactory.

Mr. Saunders (Staff Surgeon 14th Depot Battalion)

remarked that in gun-shot wounds of the hand he found that the amount of reparation by the natural process, was often surprising. In the great majority of cases, the less interference, unless to bring the parts together, the better for the patient.

Dr. Pirrie thought in the case under consideration it would have been as well to have given the finger a chance.

Dr. Dill thought that Dr. Beck went too far in his statement and that perhaps in this case, as in many others, the best chance of giving the patient a useful hand lay in the operation.

Dr. Moore replied and stated that from his experience in such matters, he thought that the operation was necessary, that the bone protruded too far beyond the soft parts, and that the latter were too much torn to form a good covering for the bone. He did not like secondary operations which generally turned out unsatisfactorily, and therefore thought that it was better to perform the operation in question, which still left the patient a very useful hand.

J. Creery Ferguson, President

17th January, 1863

Present, Drs. Ferguson (President, in the chair), Patterson, Ferguson H. S., MacCormac W., Gribbin, Pirrie, McCrea, Dill, Beck, McGee Michael, MacCormac, MacWilliams, and D. Moore.

Dr. David Moore in the absence of Dr. Murney brought forward the report of a case of Wutzer's operation.

24th January, 1863

Present, the President (in the chair), Drs. McGee (Michael), Beck, Gribbin, McCrea, Dill, McCourt, Patterson, Cuming, Pirrie, MacWilliams, and MacCormac W.

Dr. Beck read a case of perforation after turning in order to complete delivery. His paper was most interesting and practical. He also shewed a loop of woollen tape attached to a whale bone rod, which he found very useful when employing traction on leg of child as it did not slip, and the force could be applied equally.

Paper:¹ *In order to understand fully the following case, it will be necessary to make a few remarks on the two previous confinements:*

Mrs. Q_ , a strong, healthy, apparently well-made woman, engaged me to attend her in her fourth confinement, informing me that her previous child, the third, had been dead born, after a very severe and protracted labour. Her fourth labour commenced at seven in the evening, and terminated at half-past four in the morning—nine hours. There was nothing remarkable in this labour; everything was natural, and proceeded very well till towards the conclusion of the labour,

when the pains began to flag, and I had to give a dose of secale cornutum. This had the desired effect; the labour terminated favourably, and she made a good recovery. This child was an average-sized female. In her next, the fifth, confinement the pains set in strong at seven in the evening, continuing strong and regular, but with little effect, all night. In the morning, judging that the natural efforts would not be sufficient, I sent for the forceps. Before they arrived, an energetic pain sent the head, with a snap and a plunge, which were distinctly audible, off the promontory of the sacrum and into the cavity of the pelvis. Another pain or two settled the matter, and again a female child was born. The placenta soon followed. But this time she had a smart attack of metritis, from which, however, she made a good recovery. I attribute this attack of inflammation to the prolonged pressure sustained by the uterine wall, between the head of the child and the promontory of the sacrum, and I believe it would not have occurred had the forceps been applied, as I had wished, a few hours before they were sent for, and the uterus assisted during the immense exertion necessary to drive the head over the promontory of the sacrum. This child was so much larger than the previous one as to account for the extra difficulty. Her next labour, to which I wish more particularly to direct your attention, set in about two o'clock in the day. The pains were slow at first, but became stronger, more regular and energetic, as time wore on. During the night, finding the progress not at all satisfactory, nor in proportion to the state of the soft parts and the character of the pains, I came to the conclusion that something ought to be done. Finding the os uteri soft, well dilated, and very easily dilatable, I determined on turning. This I had done several times before, and with, at least, the advantage to the mother of terminating the labour speedily, which, in some cases, is a great thing gained. I cannot say so much as to its advantage to the child. On proceeding to turn I found no difficulty in introducing the hand and laying hold of the foot, but that was all I could do. Though I had it fairly in my hand I could produce no effect on the position of the child by pulling. While I was insinuating my hand and finding the foot, I ascertained that the head was large and hard, well ossified; the vertex towards the left sacro-iliac junction, and, during each remission of the uterine action, it retired before the hand much easier than I expected; still I could produce no effect on the position of the child.

I therefore withdrew my hand under the conviction that the forceps would be useless, and that perforation was the thing necessary to be done, and the sooner it was done the better. So firm was this conviction that I did not attempt to apply the forceps, though I had them at hand at the time. I explained the matter, as far as was necessary, to the husband, and requested him to bring another medical man. He brought another, who, after examining and considering the case, advised

¹ [Dublin Medical Press, 1863, v49, p215.]

chloroform or opium to be administered, and that after that we should wait five or six hours to see what would turn up; at all events to do nothing immediately. I differed entirely from all this. I was for immediate delivery, and gave the following reasons:—1st. She had already been twenty-four hours nearly in good, strong, regular, energetic labour, and the child's head was still above the brim of the pelvis. 2nd. The patient's strength was beginning to fail; and, 3rd. I had a vivid recollection of the narrow escape she had after her last confinement from inflammation; in short, I believed it absolutely necessary for her safety that she should be delivered immediately, and proposed to do so myself, either by turning or perforation, if he was agreeable, or that he himself should try the forceps first. Turning was at last agreed on. I again laid hold of the foot easily, but neither of us could produce any effect with the naked hand. The loop was then cast round the ankle, and, after a very unusual amount of strong pulling, we succeeded in getting down first one foot, then the other. This is the loop and whalebone contrivance [exhibited] that I have found to answer best for turning when the hand cannot retain its hold on the foot. The arms next gave us considerable trouble; however, they were produced; but, just as I had anticipated, we were as far off our point as ever. The head was still above the brim of the pelvis, and there it would remain notwithstanding an amount of pulling and jerking that led me to fear we were about to break the neck and leave the head in utero, as was done in a celebrated case which some of us may remember. After many ineffectual attempts to move the head with the hands, the forceps were tried in vain, and it was found to be necessary to evacuate the brain with the perforator, &c., before we could succeed in extracting it.

This child was a male, and still larger than either of the other two. The placenta soon followed, and our patient recovered without an unfavourable symptom. There are two reasons why she made a good recovery this time as contrasted with the last:—1st. She was more frightened and took better care of herself. Those of us who practise midwifery know how difficult it is to get even a very sensible, strong-minded patient to take the proper care of herself, unless when she is thoroughly frightened; but 2nd, and chiefly, though she was twenty-four hours ill in this labour, and only sixteen hours in the previous one, yet here the head had never descended into the pelvis, and the pressure which the walls of the uterus sustained between the head and the pelvis was more general, distributed over a larger surface, and though longer continued, was not particularly severe on any one point; whereas in the former labour the wall of the uterus was severely pinched or jammed at a point opposite the sacrum, in consequence of the partial descent of the head, and I have no doubt, it was from this point the inflammation set out in that case. Had we waited six or eight hours longer in this case, I

much doubt I would have had a very different story to tell as to the result. The lesson I would draw from this case is, that as soon as we can make up our minds that the natural efforts will be insufficient to bring forth a living child, the sooner we interfere to assist Nature in delivering the patient the better. In this case I would have had no hesitation in perforating at once, as being the easiest and safest, as well as the speediest method of delivering the mother from her trouble. I must confess I felt scarcely justified in inflicting on the uterus the great amount of physical violence necessarily incidental to this case of turning, particularly after coming to the conclusion that the child had not the shadow of a chance of being born alive. However I am glad, under all the circumstances, it had its chance—more particularly as it served to satisfy the religious scruples of both my patient and my medical confrère. Indeed mothers themselves who are unfortunate enough to have experienced three or four cases like this, will not suffer you to do anything but perforate, if they can help it. I could give the notes of a case where I was sent for by the mother, expressly, as she coolly informed me when I arrived, to perforate a fourth child, and I was scarcely permitted to attempt to deliver, first by turning and then by the forceps; but I did so under the energetic protests of the mother, who had been thoroughly exhausted by suffering; and though almost breathless, kept constantly crying out, “don't hurt me; but open the child's head at once, as I know nothing else will do;” and I had to open the child's head as a dernier resort, as nothing else would do. And let me remark that this patient was not a nervous woman, easily frightened, but a strong-minded, sensible woman, with more patience than is usually manifested under these circumstances.

Dr. Dill considered that Dr. Beck's paper corroborated his own view as to the impropriety of turning in a narrow pelvis. He differed from a prominent authority (Dr. Simpson) on that point, Dr. Simpson believing it possible to turn when the ant-posterior diameter of the pelvis was not less than 3 inches. Dr. Dill on the contrary thought it better practice and safer to the mother to perforate at once without turning.

Dr. Beck stated in reply that he would not attempt version except when it could be readily done. He does not think it a favourable operation for preservation of child. He therefore would perforate at once, where the head was too large or the pelvis too small. He was, likewise, opposed to Dr. Simpson's views.

Dr. M. McGee then proceeded to read an account of two cases illustrative of conservative surgery.

Paper:¹ The notes of the two following cases, in my humble opinion, may not unreasonably be designated illustrations of conservative surgery. Some time ago I

¹ [Dublin Medical Press, 1863, v49, p215.]

was requested to visit, in all haste, John M., who was represented to me to have lost his hand by the bursting of a rifle barrel. I saw him about six hours after the accident; the hand had the appearance of half-charred wood; the thumb was in its full length greatly contused; the index finger blown off; the remaining three denuded of all flesh, except the first metacarpal phalanx of the second finger which was partially covered.

The hand was lacerated half way up to the annular ligament.

The hæmorrhage was in this, as generally in all such cases trifling, but evidently arterial.

From the description of the injury all would concur with me that it was one demanding immediate amputation. I went prepared for and determined on operating. On informing my patient that he must allow me to do so, in order to save his life, I was bluntly but resolutely told by him that he never would submit to such a thing.

Not being able to convince him of its urgent necessity, I left after desiring his friends to use cold-water dressing to the part, with the expectation that I would have it all my own way when next sent for. I visited him the next morning, and, although he suffered very much the preceding night, he still adhered to the resolution of keeping the hand, I could not altogether abandon the man in his then pitiable condition. I took off, after a great deal of opposition on his part, the fingers, leaving on, much against my wish the metacarpal phalanx of the second finger, drew the hand together with a small roller, and recommended cold water to be kept constantly poured over it.

This would seem to some as if committing my unfortunate patient altogether to the salutary operation of the *vis medicatrix naturæ*.

On the third day he complained greatly of sharp pains in the part, and felt very uncomfortable from symptomatic fever.

I gave him two grains of opium every night, ordered the cold water to be continued as before. This course of treatment was regularly carried out with very little change, until suppuration commenced, which, in a short time, became very copious and offensive. Left off the cold water, used hot-water dressing and poultices, and allowed him a liberal quantity of wine and beef tea. At the end of a week the discharge was less in quantity and healthier in quality. The yeast poultices were then applied and persevered in for some time, until healthy granulations appeared in the palm. It was ultimately dressed with a stimulating ointment.

I attended him better than two months. He can now, strange to say, write with the thumb and metacarpal phalanx of the second finger, and in many other respects finds it very useful to him.

Shortly after attending to the above case, John, a labourer, aged 22 years, of a very healthy appearance, was brought to my place, having got his hand entangled

between the wheels used in propelling a threshing machine. The thumb and two first fingers were severely contused, and in a great measure stripped of their natural covering. The third and little fingers, with their metacarpals, were comminuted; the other metacarpal bones were very much exposed on the palmar side.

Recollecting the agreeable but quite unexpected result of a similar but more serious injury, I took away the third and little fingers, with their metacarpals, and left remaining half of the hand with thumb and fingers, then appearing in almost a hopeless condition. The subsequent treatment was much the same as in the former case. He was well in six weeks. Immobility of the fingers continued for some time longer. He is now able, with very little inconvenience, to work at his ordinary calling.

For several years I had the practice of a large district of country, where several mills were pretty regularly at work dressing flax. My experience in treating injuries of the hand received in them, and otherwise, has been rather considerable.

I am now fully convinced, from what I have seen, read, and heard of such accidents, that it would be much better if more conservative and less radical surgery were practised, and the operator to study more the future benefit of his patients, and less his own credit, in forming a neat stump. We would then have that inestimable appendage to man, the hand, in many cases, wholly or in part, preserved to and in possession of its owner, instead of being so generally, and I fear unnecessarily mutilated, knowing as we do that wounds in those parts are comparatively easily healed, being so plentifully supplied with blood-vessels and nerves.

Dr. Beck agreed with the views put forward by Dr. McGee. Under even most unfavourable circumstances, he would be most unwilling to amputate any portion of the hand. Dr. Beck then instanced several cases of injury of the hand, in which extraordinary success had followed attempts at conservative surgery.

Dr. W. MacCormac thought that every possible chance should be given in order to preserve any portion of an injured hand, but in so doing, the general health and condition of the patient were not to be overlooked; as they much affect the favourable termination of such cases. In injuries happening to mill workers, he had frequently noticed that wounds would apparently heal up by the first intention, and afterwards the adhesions would break down, unhealthy suppuration set in and the case terminate unfavourably.

Dr. Pirrie thought that every chance should be given in order to preserve as much as possible of an injured hand.

The President thought that the marked tendency of

the present day was towards conservatism in surgery. Dr. Cuming asked if it were observed in practice that bad results often followed the non-performance of operations in cases of severe injury apparently requiring such. He thought that purulent absorption, irritative fever, or other accidents might ensue.

Dr. Beck had had large experience in the treatment of such injuries and had never seen bad results follow the attempts to preserve the hand.

Dr. McGee briefly replied.

Dr. Dill then exhibited a heart which had been removed from a patient who had died in hospital, who had sometime previously been under Dr. Ferguson's care for a pemphigoid eruption of the skin, and from which he had recovered and left the hospital.¹ The patient had suffered from the heart disease for some 10 years. On examination Dr. Dill had found extensive dullness in the pre-cordial region, a murmur with the second sound. There was much dyspnoea, the lower extremities were swollen and the urine albuminous. The heart was found to be considerably dilated but not much hypertrophied, weight 233. 2drs. There was extensive deposit in the aortic valves which also extended into the ventricle for about an inch on one side, all the other valves were healthy. The hydrostatic test shewed insufficiency of the aortic valves. The President, while the patient was under his care, observed a murmur with both sounds of the heart and the other sounds of patent aortic valves. He had then no dyspnoea or cardiac distress.

Dr. Cuming thought it would be interesting to know how far the therapeutic means displayed to remove the skin affection affected the fatal issue of the case. It appeared that on the disappearance of the skin disease the heart symptoms were suddenly and severely aggravated. He thought the application of amoxa would have been worthy of a trial as a therapeutic means to combat the heart disease. The treatment employed by the President was mainly feeding and wine. With reference to the amoxa it did not imitate exactly the natural derivative supplied by the affection of the skin.

Dr. Patterson was acquainted with a gentleman affected with heart disease, in whom the formation of an ulcer greatly relieved the distress, while its subsequent appearance was soon after followed by death.

Dr. Dill observed with reference to a remark of the President, that when he, Dr. Dill, examined the patient, although he suspected its presence, he was not able to distinguish a murmur with the first sound, as the bruit with the second sound was so loud and prolonged as quite to conceal that with the first.

J. Creery Ferguson, President

January 31st, 1863

Present, the President (in the chair), Drs. Dill, Gribbin, W. MacCormac, McCrea, J. Moore, MacWilliams, Patterson, Pirrie, Saunders, Brice Smyth, Stewart.

The minutes of the previous meeting were read and confirmed.

Dr. Dill introduced an elderly woman who had become a hospital patient of his a few days ago. He said that she had been employed for years in a looking glass factory, in which she wrought a good deal with mercury; she has a tremor—a palsy—all over, which she ascribes to this occupation. He considered the tremor different from that of paralysis agitans, and chorea; and suggested as an interesting point to decide, whether the disease was caused by mercury or was sui genesis. He is adopting the same principles of treatment as in any other nervous affection, and is, therefore, using iron and quinine. He believed that the vapour alone of mercury was sufficient in producing such symptoms. He called attention [to] the fact that when the trembling parts are supported in anyway, the motion ceases.

The patient, in reply to questions of the members of the Society, stated that she was 42 years of age. She had been, for twenty-three years working at the business, that she had been obliged to handle, very often, the quicksilver-refuse, that her hands used to be blackened with this, that she had been thus engaged daily, that the tradesmen wrought only a day or two in the week, but were nevertheless, affected with fetor of the breath. That, first of all, she had had a “burning” sensation in the stomach, then lightness of the head, “sleepiness” in the lower limbs, occasional trembling of the knees, that two years ago she had been wet in a shower of rain after which her teeth loosened, and they had not since become fixed. That at present she suffered from a pain in the left shoulder, that she had been getting worse for the last six months, and had given up working three months ago.

The President said that, in consequence of the manufacturing being conducted at ordinary temperatures the mercury must be vaporised in exceedingly minute quantities, if at all. He had known pure chorea attributed to the vapour of mercury. It would be impossible to account the vagaries of nervous disease. He did not think it had been clearly proved that this was a case of mercurial tremor or that it was the result of mercury in the vaporised state. He leaned to the use of Iodida potassii in mercurial poisoning.

Dr. W. MacCormac thought there was no doubt of this being mercurial palsy; that the woman had got a chill, her secretions had stopped and her present affection had come on. This case shewed very plainly the fallacy competed by those who attributed symptoms of tertiary syphilis to mercury. Here was a woman as strongly under the mercurial influence as she well could be, in whom none of the phenomena of tertiary syphilis were exhibited. The mercury, in an

¹ [See page 975.]

oxidised condition might have been absorbed through the hands.

Dr. MacWilliams remembered seeing a case in which iodide of potassium has been useful.

Dr. Saunders remarked that it was a strange thing that the disease was so rare, so many people being exposed to its cause. In many persons in whom mercurial treatment has been pushed to extremities, no such symptoms had appeared.

Dr. J. Moore introduced a case of elephantiasis occurring in a young fellow of twenty-two, or so. Both legs were greatly enlarged. The patient stated that the left leg had been enlarged since he was very young, and that he remembered when the right one was perfectly well—about five years ago.

He had always lived with his parents in the vicinity of Antrim. He felt no pain, or tenderness on pressure in any part of the limbs. It was ordered that a cast of his limbs should be taken.

Dr. J. Moore had met with a similar case in the neighbourhood of Ballymena, not, he thought three miles distant from the residence of the present patient. He thought the kidneys were affected, but believed that there was nothing the matter with the urine. Perspiration was good. In the Ballymena case, the biggest leg was not so big as the smallest in this case.

Mr. McCourt had met with a case of this disease at Gracehill which is in the same district. The legs broke up, there was frightful discharge, and the patient died.

Dr. W. MacCormac said the disease was generally attributed to inflammation of the absorbent vessels and glands, that it was unusual in both limbs. Amputation he said was useless in initial stages, it only hastened the outbreak in another portion of the body. It was to be observed that in this case the disease commenced at different periods in the two limbs. In the intercalated form of the disease—the E. Græcorum—the senses were affected, in this boy they were sound.

The President looked on elephantiasis as an inflammatory disease, this as the chronic stage of it. In it the absorbent and venous systems, and the areolar tissues were affected. He would treat it locally by almost constant vapour baths, and he would push the iodine treatment to extremity. He would be disinclined to use pressure bandages. He observed that on the foot there were tumours like *molluscom tuberosum*.

Dr. Pirrie exhibited pieces of *Laminaria digitata*, intended as a substitute for the sponge-tent. He had selected two pieces of as nearly as possible the same size. One he had immersed for twenty four hours in water; it had expanded both longitudinally and laterally to nearly double the size of the other. The irregularities of the surface disappear as the pieces

swell. When swollen they are elastic. The profession was indebted to Dr. Sloan of Ayr for the introduction of this agent.

J. Creery Ferguson, President

Pathological Room

February 7th, 1863

Present, the President in the chair, Drs. Thomas Reade, Beck, Dill, W. MacCormac, MacWilliams, McCrea, Patterson, Michael McGee, Cuming, McCourt, D. Moore.

The minutes of the previous meeting having been read and confirmed, a letter from the Editor of the "Dublin Medical Press" was read relative to the reprinting of the transactions of the Society and offering to throw off a hundred copies of the size of the Report of the Medical Benevolent Fund, at the rate of a guinea per sheet. The Secretary was instructed to write the Editor and inform him that the Society would accept his terms.

Two accounts, one for twelve months July 1862/63, subscription "Northern Whig", £1.6.0; one of "Musgrave Brothers" of £3.14.2½ were passed and payment ordered by the President.

Dr. David Moore exhibited the recent parts of a case of fracture of the base of the skull, and detailed the facts of the case.

Dr. Thomas Reade thought a fracture of the base of the skull of any magnitude was a necessarily fatal accident. He was not aware of any preparation which would shew bony union of a fractured base, and lead to the inference that recovery had taken place.

The President enquired as to how the force acting laterally on the skull, would produce a transverse fracture of the base.

Dr. W. MacCormac remembered a case of very extensive fracture of base of skull; the subject of it was a sergeant upon whose head a metal butt of many hundred weight fell while he was engaged in moving it, crushing his head laterally between it and another butt which was lying on the ground. The direction of the force was lateral, though fracture of the base of the skull was transverse, with a fissure extending backwards on either side from the petrous part of the temporal bone towards the occipital foramen.

Dr. D. Moore remarked that the course the fracture took in the instance brought forward was that taken by all the extensive fractures of the base he had seen, and this course seemed to obtain irrespective of the direction of the force, and mentioned the case of a man who had fallen from a considerable height, alighting on the vertex of the skull. Whilst in hospital he shewed the usual signs of fractured base, and on post-mortem examination a transverse fracture was found which pursued almost the same course as the one under discussion.

A communication was read from Dr. Scott, Aughna-

cloy, on the use and mode of action of Ergot of Rye.

Paper:¹ To the physician regularly or even occasionally engaged in the practice of midwifery or the diseases of females, there are, I think, few subjects better deserving of accurate attention than the action of ergot of rye, and perhaps emetic medicines generally. The questions involved are deeply interesting, and demand the most careful consideration, and certainly can alone be answered satisfactorily by obtaining the results of a large number of cases (from trustworthy sources) treated by ergot, ipecacuanha, and other emetics.

The readers of the medical journals have seen that Dr. Hewitt, of London, propounds, at least in meaning, these queries:—Whether, in cases of marked ergotic effect, that effect be coexistent with vomiting or nausea? In cases where ergot has been given without effect, is there an absence of vomiting or nausea? Ipecacuanha or any other emetic being given, are the contractions of the uterus intensified thereby or increased in frequency? During a rather extensive midwifery practice, extending over twenty years, I have exhibited ergot of rye, previous to the expulsion of the fœtus, and with the object of exciting uterine action, more than one hundred times. The result, with a single exception, invariably answered my most sanguine expectations. I have repeatedly asked others for their opinions on the subject, and almost invariably received replies in substance confirmatory of my own experience. Not long since a most intelligent practitioner, in a neighbouring county, engaged in a large obstetric practice, said in my hearing, “I have been frequently disappointed in the use of every medicine I ever ordered, save ergot of rye, that never failed me.” All this, of course, only goes to establish the value of the ergot, which, I suppose, nobody questions, and that, in a considerable number of cases, failure was almost unknown, leaving the question of the coexistence of the ergotic effect and vomiting untouched. I can, however, most certainly reply that in the cases above-mentioned vomiting and nausea were the exception, and not, I am persuaded, of more frequent occurrence than in cases where no ergot was administered. Having only seen, some six years since, an individual case where the ergot failed to accomplish the object contemplated, and having taken no note of the matter, I am unable, of course, to say anything with respect to whether, in those cases where no ergotic effect is produced, vomiting and nausea be also absent. That uterine contractions are intensified, if not aroused, by emetic medicines, I presume there can be little doubt. In one case I witnessed, what I did not anticipate, powerful uterine contractions immediately following a sickening dose of tartar emetic. But whatever the relation (if any) of uterine action to vomiting or nausea, it is I think tolerably clear, from the results

of the cases above referred to, that there is no very strong foundation for the recent statement of the Lecturer on Midwifery, at St. Mary’s Hospital, “that ergot given without producing vomiting will generally be found useless as a parturifacient.”¹ Whether there be any immediate or remote connexion between imperfect contraction of the womb and puerperal fever, I am still in doubt; but I never had an opportunity of observing a case of the latter where I was aware that ergot had been administered, and it certainly did not make its appearance in any instance where, owing to personal attendance from the commencement, I knew that proper contraction of the womb had taken place. I attach great importance to ergot in the treatment of hæmorrhage after delivery, so much so that, some years since, I adopted the practice, in every case where, from existing symptoms or past experience, there was reason to fear hæmorrhage, of giving a dose of the ergot immediately preceding or subsequent to the birth of the child, and with invariable success; indeed, to this practice I principally attribute the agreeable fact that, save when a student in a lying-in-hospital, I never saw a fatal midwifery case.

To the want of careful selection and due preparation I believe should be nearly altogether attributed the occasional unsatisfactory effect, or rather want of effect, of ergot in exciting uterine action. I cannot help thinking that, if it were cut into small pieces, or bruised in a mortar immediately before use, then boiled for about six or eight minutes and administered warm, the just expectations of the physician would hardly ever meet with disappointment, to say nothing of the benefit conferred on the patient.

My sole object in forwarding this communication is because I think the whole subject eminently deserving of the best attention of our Society, especially in its more practical aspect, and that I am really desirous of learning how far the members may coincide, or the reverse, with the remarks so crudely and hastily placed before them.

Dr. Michael McGee had given Ergot for the last twenty years, and in the same manner as Dr. Scott, and regretted to have to state that from experience he had been often disappointed in it, in the proportion of six cases out of ten in which it was given.

Dr. Beck had much experience of Ergot. He had used it 400 times in 2,000 cases. If it failed he thought failure due to its being employed in inappropriate cases. It should not be given till the uterus had made some progress itself in the labour, the os well dilated, and then only when the pains were not “up to par”. He considered the Etherial tinct. was not to be depended on. The Ergot should be recently bruised as it does not keep owing to an acarus forming on it but Cam-

¹ [Dublin Medical Press, 1863, v49, p342.]

¹ See *Lancet and Dublin Medical Press, &c.*, of last week.

phor would preserve it from the acarus.

His mode of prescribing it was to make an infusion of *zij* of the Ergot, and divide that into three doses, with an interval of twenty minutes between them. He could not class Ergot as an emetic as he had met with vomiting as often where Ergot was not given, as in those cases when it was administered, and besides vomiting was frequent whenever the pains were strong in cases where Ergot was not required. It was most valuable in cases of post-partum hæmorrhage. As to its stated effects on the child itself, he thought it could only arise where Ergot had been given at a very early stage of labour and continued long enough to act as a poison to the child. He had never seen such effect.

Dr. Patterson had used Ergot for the last thirty years and thought all junior practitioners should be cautioned against its indiscriminate use. It should only be used when the cervix is well dilated, the passages soft, and free from any obstruction to the passage of the child. In cases of retained placenta or of hæmorrhage he invariably gave a dose of Ergot, when the child was about to be expelled. If Ergot was given too early there was a risk of rupture of the uterus, a case of which in consequence of the incautious use of Ergot he had heard Dr. Hamilton of Edinburgh commenting on.

Dr. Thomas Reade remarked that Dr. Beattie of Dublin had written a paper on the subject, in which he recommended Ergot to be given only in latter stages of labour, or after birth. Where an apprehension of hæmorrhage exists, he advises a dose of Ergot just before delivery to guard against it.

Dr. Cuming confessed he was startled by the number of cases in which Dr. Scott used Ergot, and Dr. Beck also used it very frequently. Now in 100 cases he had never used Ergot at all. The statistics of midwifery shew that abnormal cases as a class occur but once in 33 times, and he felt surprised that in an ordinary physiological process as childbirth was, Dr. Beck should feel called on to add Ergot so often.

Dr. Michael McGee did not use Ergot in one case in 30.

Dr. Johnston asked if there were any connection between imperfect tertiary contractions and puerperal fever.

Dr. McCrea considered that puerperal fever was less owing to deficient uterine action than that the deficient action was due to the cause which at the same time gave rise to the puerperal fever.

Dr. Beck thought he could trace a distinct connection between rigid contraction of uterus after birth, and the absence of puerperal fever.

Dr. Dill could not agree with Dr. Beck as to Ergot being the most efficacious agent.

J. Creery Ferguson, President

Pathological Room

February 14th, 1863

Present, the President in the chair, Drs. Dill, Patterson, Browne, Michael McGee, Pirrie, Corry, W. MacCormac, Beck, Cuming, Staff Surgeon Saunders.

The minutes of the previous meeting having been read and confirmed, Dr. D. Moore shewed a fœtus in utero of eight months gestation, the uterus and content having been obtained from the body of a female who had died of acute pleurisy. The child and placenta were both in a natural position—that of the child was the second position of labour the occiput to the right obturator foramen, the right hand was placed on the top of the head. Would the hand present in the progress of the labour?

Dr. Pirrie said that when labour would begin the head would be projected forwards and the hand would most probably recede.

Dr. Beck said that when the hand came down with the head, it was placed usually at the side of the head and face, and not on the vertex.

Dr. Cuming asked if in such a case section of the abdomen would offer any chance of life to the child.

Dr. Michael McGee quoted the case of a fœtus which had been cut out of the uterus at the end of the period of gestation, the mother having died from convulsions. The child lived and grew up to manhood.

The President remarked that in the present case the woman had died not from a disease of very short duration but more lingeringly, which would doubtless have an effect on the vitality of the fœtus. That death had occurred more suddenly than was anticipated, and in the middle of the night, even had a *sectio abdominis* been contemplated in such a case, and a surgeon ready when the final event occurred to take advantage of every moment he considered the chances of the child's life would even then be very problematical.

Dr. Corry exhibited a case in which a congenital tumour of the size of a small orange projected from the centre of the occipital bone of a child a few days old. A narrow neck, rather firm and somewhat moveable connected the tumour to the bone. The tumour itself was tense, elastic and devoid of pulsation, of a reddish colour at the position nearest the pedicle, the remainder was more purplish in hue.

Dr. Beck met with two such cases, in one the child was still-born from difficult labour, the side of the head presenting the remains of the cyst of such a tumour as he conceived the one before the Society to be, with a little round hole in the centre of the parietal bone communicating with the cavity of the arachnoid. In the second case, the tumour was situated on the occiput and presented a very similar appearance to the case before the Society.

Dr. W. MacCormac thought the tumour was rather of the character of nevus, as the pedicle was moveable rather freely on the parts beneath. There was a

marked difference of colour in different parts of the tumour and the absence of pulsation might be accounted for by the tumour being composed chiefly of enlarged vein.

Dr. Browne considered the case was one of spina bifida, that the tumour was lined by the arachnoid, and filled with its fluid, it was partially translucent. That the tumour could not be lessened in size by pressure as the foramen in the bone was of small size. In spina bifida affecting the inferior extremity of the spinal canal although the opening was large, the tumour was but little affected by pressure.

[The following paper by Dr. J. W. Beck is recorded in the Dublin Medical Press but not in the minutes. The discussion is recorded in both.]

Paper:¹ Having practised midwifery now for upwards of twenty-seven years, and having registered every case as it occurred for sixteen years and seven months of that period, I find that I have considerably above 2000 cases on my register. Case No. 1000 was delivered by me on the 3rd day of August, 1855, and in these 1000 cases I have administered the secale 126 times. Case No. 2000 was delivered by me on the 16th day of July, 1862, less than seven years afterwards, and in this second 1000, I have administered the same drug 170 times; in all, 296 times in 2000 cases. Now, as I know positively that I administered the secale cornutum 296 times, in a practice extending over sixteen years and two months, I presume I was justified in assuming, as I did at our last meeting, that I had administered this agent “about 400 times” in a midwifery practice of upwards of twenty-seven years.

With regard to its effects on the mother—I have registered them in four degrees as follows:—First, where it had apparently no effect at all. Second, where it had very little or very doubtful, if any effect. Third, where it had a decided effect, such as was expected and required. And lastly, where the effect was remarkably and perhaps unexpectedly rapid and energetic. Of the first, I find no effect in 15 cases; a very little or doubtful effect in 42; the good effects expected in 223; and an extraordinarily energetic action in 16 cases. Now, as these remarks were written down immediately after each case, I think they are much more to be depended on than any vague general impression, and the result appears very favourable to this drug when administered in appropriate cases.

I need not enter into the consideration of what constitutes an appropriate case for its use, but I may remark that it should never, under any circumstances, be given in the early stage of labour, before the os uteri is well opened, no matter what the pains may appear like. There are few things more annoying to the accoucheur than to be in attendance, for perhaps a day

or two, on a patient who considers herself in labour, and who is continually urging him to do something for her; and moreover, bad as this is with a primipara, it is still worse and more embarrassing, when it occurs, as it sometimes will, with the mother of five or six children, who considers herself a judge of labour. In a case like this the os uteri may be little if at all dilated, and the process of dilatation may be so very slow as to be scarcely perceptible, although the pains may be very severe on the patient.

Now, in a case like this, secale should not be given (at this stage, at least), as it will be sure to disappoint you in any good effects you may expect from it, and this warning is the more necessary as it is just such a case as the young practitioner is tempted to give it in. I have given it under such circumstances myself several times, but never with any benefit or satisfaction; and this leads me to remark that perhaps the report of my register would not have been so favourable as it is had it contained a list of all the cases, “about 400,” in which I administered it. I had the experience of about ten years of its use to guide me before I commenced this register; and this experience was valuable in enabling me to select the cases in which its use would be most appropriate; notwithstanding all this, however, I observe that in some of the cases where the effects are marked nil, the remark is made that it was administered too soon; so that I consider this a point worth insisting on. It seems to show that we do not always benefit as fully as we ought by our experience. On the other hand, however, I may remark, as illustrating the benefit of experience as a guide in the selection of cases proper for its administration, that of eight cases that were perforated in the 2000, in only three was secale tried; and these three occur early in the first 1000. I may observe, as a further illustration of the same thing, that the proportion of cases in which it was necessary to use the forceps after the secale, diminishes as the register advances, averaging less in the second 1000 than in the first.

If, on the contrary, the labour be in an advanced stage, the parts soft, moist and cool, and there exists no great mechanical obstruction to the advance of the fœtus—in short, in any case where it may be desirable to increase the muscular action of the uterus, either before or after parturition—its use is clearly indicated. But where the uterus has already acted energetically and failed to do its work, it is clearly inadmissible, as administering it in this case would be like the overdriving of a tired horse, and mischief must ensue.

For post-partum hæmorrhage I again repeat there is no remedy equal to it. The more I have used it, the more dependence I am inclined to place in its use. I have given it 41 times after the birth of the fœtus for hæmorrhage, retained placenta (though I always proceed to remove it by the hand), or a known lax state of the uterine tissues, tending to hæmorrhage, and I find

¹ [Dublin Medical Press, 1863, v49, p597.]

the effects marked good in all these 41 cases. In making this assertion I do not ignore position, pressure, temperature, &c., but my subject is at present the action of *secale*, and not uterine hæmorrhage.

With regard to the effects of the *secale cornutum* on the child. I have long since come to the conclusion that it has no injurious effect on the child as a poison, and the registry seems to me to confirm this opinion in a remarkable manner. In every case, except one, where the child is marked dead-born, or as having died shortly after birth, there is a perfectly sufficient reason to account for death without the necessity of falling back on the *secale*, and in this one case, though I am not perfectly satisfied as to the cause of its death, I by no means feel inclined to attribute it to the *secale*. There were twenty children at the full term, who were either born dead, or died shortly after birth, after the administration of the *secale*. Of these, eleven were delivered by the forceps and three perforated. This, I presume, is sufficient to account for these fourteen deaths without blaming the *secale*. Of the remaining six, one was putrid when born, another had been turned, the third was a case of placenta prævia, and the child died from hæmorrhage, the fourth child was born with a rigid state of the voluntary muscles, a kind of rigid catalepsy, but more like rigor mortis than anything else. The abdomen was enormously distended and tympanitic; it lived an hour, dying out quietly. The fifth child was very large, and the labour was very slow, consequently the pressure was very great and long continued. Twenty-six hours severe pressure during labour is enough to account for the death of this child. It might have been saved by the forceps, but as a rule I don't use them while the child is making any advance at all. The sixth child, though born after a labour of thirty-five hours, still seemed to me, I must admit, unlike the previous one, to have suffered no pressure sufficient to produce its death. It lived, at least the heart beat, for half an hour, but all the means I could use were unsuccessful in producing even an attempt at respiration, still I am not inclined to attribute this death to any poisonous effect of the *secale*, as I have seen two children besides die out in a very similar manner where no *secale* had been used.

I shall now address myself to a question which has been raised here as to the connexion there may be between a lax state of the uterine tissues as promoting or facilitating the absorption of putrid matter through the uterus and the production of puerperal fever; in other words, how far the administration of *secale* may, by promoting the contraction of the uterus, prevent the absorption of its putrid contents, on the absorption of which puerperal fever may be supposed to depend.

There are four deaths of mothers in these 296 cases. The first death occurred in a primipara, aged above 40 years, who was delivered by the forceps of a very large and extremely putrid child. She complained of nothing

but prostration, gradually sank into a state of coma, and died in four days. I have no doubt this death was from putrid infection. How far the *secale* tended to prevent its occurrence I can't say. It is marked as having produced very little, if any, effect. The second death was from hæmorrhage. It was a case of placenta prævia. I was called by a member of this Society to turn. I did so. She died on the twenty-seventh day after delivery. The third death was that of a patient with inflammation of the bowels, who was delivered of a four months' fœtus after eleven days' constipation, and died the next day from exhaustion. The fourth death was a primipara, delivered with great difficulty after a twenty hours' labour. The effect of the *secale* is marked "very good;" but I had evidently despaired of her being able to deliver herself, as the child was born while a messenger was away for the forceps. She died thirteen days afterwards of what is marked "putrid fever." These are all the cases of death, or puerperal fever, that occurred among the cases where *secale* was given. Whether the evidence educed from them may be pro or con I don't know, but you may take it quantum valeat.

There is just another point I would say a word or two on before concluding, and that is, the proper method of preserving and administering the *secale* itself. It is a drug the active properties of which are very easily destroyed by damp. It is also very liable to be attacked by an acarus or mite, particularly when damp. It should be procured in substance whole. I have no faith in its powder, or tincture, or extract, or anything else, but itself. After it is procured, it should be carefully dried, and put into a well-stoppered bottle, with a small piece of camphor. If this is done it will keep sound and active for a long time. The camphor seems to have the effect of preserving it from the attacks of the acarus. Again, a new parcel of the drug should never be placed in the bottle along with the old. What remains of the old stock should be taken out, the bottle well washed and dried, and your new lot, well dried over a stove, if possible, placed in it on the top of a little bit of camphor. I believe that it is from neglecting to preserve this valuable drug properly, or from prescribing some of its fancy preparations, that it so often disappoints the expectations of some practitioners as to cause them to lose faith in it. I have no hesitation in saying that if you can procure a sound lot of this drug, and preserve it in the way I have directed, you will be very seldom disappointed in its action if administered in the following manner, and I again repeat, only in appropriate cases. I know that latterly when it failed in my hands even once, and particularly if twice in succession, I was inclined to look for the cause in the bottle, and more than once found it then in the bad quality of the drug.

The way I administer the drug is as follows: I take two drachms, always fresh powdered as required, and boil it in eight or ten ounces of water for about five minutes. I administer this in three or four doses, as hot

as it can be swallowed, with from twenty minutes to half an hour between each dose. Generally two or three doses are sufficient to produce all the effects required, sometimes one dose will do. If the first or second dose produces little or no effect, you will generally find the third or fourth will produce as little, and I don't believe it is even useful or necessary to go beyond this two-drachm dose, even when the first or second dose is thrown off, as it sometimes is. When it is thrown off, it is not because it is an emetic in the ordinary sense of that word, though it has been called one. It excites the uterine action, and this action (or rather the stretching of the os uteri caused by this action) excites or produces the emetic effects on the stomach, precisely as occurs in cases when no secale has been given. Some one relates the case of a married woman who always vomited while in coitu, and I had a patient myself whom I could make retch at pleasure by touching the os uteri with the tip of the finger, although she could give no explanation herself as to the cause of the retching, or as to why she retched, yet the result of the touch was invariable. I made the discovery accidentally while examining her by the tactus eruditus. I had an opportunity of ascertaining some year or two afterwards that the os uteri had lost this peculiar irritability.

Dr. Beck's paper on Ergot—Discussion

Dr. Cuming considered that unless the cases Dr. Beck had met with in practice differed materially, at least in a great number of them, from those met by other medical men he thought Ergot was too freely administered. It was in the memory of practitioners of standing, that at one time formerly it was customary to give a glass of whiskey, and ninety drops of tincture of opii to every woman on delivery. Now this was never thought of. He supposed the exhibition of the above draught did no harm but cases are at present imagined to proceed as well without it. Dr. Beck might exhibit a small dose of arsenic to each of his cases without making any change on a favourable issue. He uses a drug largely that has in other hands been productive of bad effects, and which has a decided effect on the nervous system, evidence of nausea and depression.

Dr. Michael McGee has had experience in 3,000 cases of midwifery. In his early practice he gave the drug more frequently than now, first to accelerate delivery and second to save time. He thinks the good effects he then ascribed to the drug would have appeared in its absence. Could it not have been dispensed within some cases of Dr. Beck's. In some cases where the uterine action has declined, it is injurious to both mother and child, and has sometimes acts as a sedative merely. Where he has given Ergot he has met with hourglass contraction in a few cases but never when the drug was absent. He agreed with many points in Dr. Beck's paper but could not endorse all

his good opinions of Ergot.

Dr. Pirrie agreed with Dr. Beck that when Ergot failed, the fault lay more in the faulty keeping and preparation of the drug than in the drug itself. He would not agree with Dr. Beck in giving Ergot in cases of retained placenta, as it [is] very liable then to give rise to hourglass contractions. He was a pupil in the Rotunda in Dublin when Drs. Hardy and McClintock made their experiments on the action of Ergot. The conclusion they arrived at was that Ergot was productive of bad effects on the child, and the rule was that unless birth was accomplished in two hours after its first administration, the forceps should be applied. It was a most valuable agent in post-partum hæmorrhage. He had seen mischief in cases which were unsuitable for the exhibition of the medicine, but this should not be charged to the drug itself.

Dr. Browne considered the value of the paper lay in some measure on its clearness and candour. If Dr. Beck's instructions were followed, the drug good, and cases suitable, the practice inculcated would be found to answer expectation. He considered that if Ergot were given six or eight hours before the birth of a child, there would be a great risk of still-birth. He would endorse almost all the statements of Dr. Beck.

Staff Surgeon Saunders in cases of post-partum hæmorrhage never omitted the early application of the child to the breast, as there is no better excitant of uterine contraction. The infusion should be prepared on the spot from freshly powdered Ergot, and given cold. He has found the infusion given cold to act better, and it is well known that a small draught of cold water will often excite uterine action.

Dr. Dill said he should scarcely have thought it necessary to rise on the present occasion were it not to state that he did not fear to meet, and even measure swords in a friendly way with Dr. Beck on this or any other question. He thought it better to debate the point now, rather than like him to take a week to barb an arrow or direct a shaft.

Notwithstanding what Dr. Beck had said in defence of Ergot of Rye as the very best agent in the hands of an accoucheur for checking post-partum hæmorrhage, he was still disposed to reiterate and advocate pressure and the free application of cold as the first, superior and most effective agents we have at our command. Pressure over the uterus can always be promptly applied by the hands and cold water, (ice if possible) should never be far off. Whereas Ergot required time for preparation and still longer after its administration till its influence, if any, was felt. He need scarcely allude to Dr. Beck's hypercriticism regarding the fact that he did not mention or recommend horizontal position as the first thing to be attended to. It was not necessary to tell him that the patient was supposed to be already in that position and when Dr. Beck did introduce the point in an elab-

orately written paper and attempted critical argument, why did he not inform the Society how the head should be lowered and the hips elevated. This Dr. Dill had always in such cases been in the habit both of practising and teaching. Indeed he held that the head be very much lower below the level of the body, and the hips at the same time considerably elevated. This would appear the more necessary when it was known that the saving of a single drop of the vital fluid in such cases of the utmost importance, and this position it should be admitted was calculated to accomplish the object. There were few specifics in medicine but he would be dishonest to look on Ergot as one of that class and that it exercised great influence over the womb in contracting its muscular tissue but he was not prepared to admit that it should be placed either in the class of poisonous emetics.

**Pathological Room
February 21, 1863**

Present, the President in the chair, Drs. Browne, Dill, Cuming, McCrea, Charles Purdon, McCourt, Gribbin, Johnston, Staff Surgeon Saunders.

The minutes of the previous meeting having been read and confirmed Dr. Charles Purdon exhibited a specimen of soup he had caused to be made for the use of the inmates of the "Deaf and Dumb Institution" of which he had medical charge. He stated that the pupils were particularly liable to strumous affections, phthisis chiefly, with a large mortality. The diet was abundant and generous, and with tonics, expectorants, and cod liver oil, freely [used], constituted the treatment formerly pursued. Owing to its inefficiency he had introduced the use of the soup laid before the Society, which for the past four months had been used daily as part of the food of the pupils, the cod liver oil so freely administered before being at the same time discontinued.

The result had exceeded his expectations a wonderful exemption from phthisis and asthma generally having been enjoyed for the past four months by his patients, who had become fat and healthy looking.

The following are the constituents of the soup

Rx	Flax seed	℥[ss?]
	Bran	℥i
	Beef	℥xii
	Groats and Vegetables	
	Water	Oij

The flax seed and bran are boiled in water for two hours, strained, and the fluid then boiled with the beef and vegetables for a sufficient time with water enough to give two pints of soup.

The President introduced a case of large abdominal tumour in a boy _ years old and asked the opinion of the Society as to its nature, and the probable result.

Dr. Browne considered the tumour to be connected

with, and confined to, the mesentery, mesenteric glands and spleen; to be malignant from the cachectic appearance of the patient and the rapidity of its progress. There was little or no fluid present—he could detect no fluctuation anywhere. Has at present a case under his care in which effusion had twice occurred from malignant disease of the abdomen. Prognosis unfavourable.

Dr. Dill thought that the tumour was not due to malignant disease, but to a strumous enlargement of the mesenteric glands, that the spleen was not involved, that there was considerable effusion, but that it had not been detected from the imperfect means of examination the Society had had, as the boy was recumbent in a large basket and had not been placed in the erect posture, and that the tumour itself was not so large as to fill the abdomen to the extent existing in the case, without much effusion. In the prognosis he agreed with Dr. Browne.

The President had been unable to detect fluid; if any, he thought it was slight in amount. The enlargement raised considerably even in twenty four hours. Tympanites would account for much of it. In addition to the morbid deposit in the mesentery and its glands, there was a tumour which occupied somewhat of the site of the spleen, but which was not in his mind splenic, differing from that viscus in size, in form, and somewhat in site.

He considered the morbid process had also extended to the spleen. It was a common site of tubercular deposit. Where was the æriform effusion? Was it confined to the intestinal canal, or did it exist in the peritoneal cavity as a secretion from the sero-membrane. The presence of air in the intestine itself would be sufficient to account for the amount of the swelling. The bowels were in good order and evacuation regular. The pressure of the tumour on the abdominal veins would account for the œdema of the limbs and scrotum.

The President next exhibited a case of pulsating tumour of the thorax and asked for the opinion of the Society as to its nature.

Dr. Cuming said such a pulsating tumour might be produced by an aneurism, by malignant disease of the lung, or by the pointing of a pleuritic abscess, to which a pulsation had been communicated. The absence of dyspnœa, dysphagia, of any bruit, of differences in the radial pulse would to some extent militate against the idea of aneurism. The history of the case is not that of pleuritic abscess. From the imperfect means of examination of the case afforded Dr. Cuming he felt inclined to avoid any opinion on it, but so far, it seems to be probably a case of cancerous affection of the lung.

Staff Surgeon Saunders said that the paroxysmal attacks of dyspnœa on exertion he considered an important feature in the case, which seemed to him to

be one of aneurism. It was not necessary in aneurismal swellings to have a murmur, or alteration in radial pulse, or any indication of heart disease. He remembered a case of aneurism in a soldier which opened into the trachea.

During life the only symptom observable was an asthmatic state of respiration. A few days before death the lips became perfectly pale and bloodless, shewing an accumulation or partial stagnation of the blood in some of the internal organs.

In another case the aneurism presented on the root of the left lung, and the only symptoms during life were those of difficulty of breathing with some bronchitis. Swellings such as the one before the Society were obscure but from a cursory examination he leaned to the idea of aneurism.

Dr. Johnston thought the case one of aneurism. Presence of bruit was not necessary. Malignant disease would scarcely account for the circumscribed pointing of the tumour, and with it there would be more constitutional disturbance. The extensive dullness might be partly accounted for by partial pleuritic effusion. He considered the case very similar to one brought some years ago before the notice of the Society by the late Dr. Malcolm.

The President looked on the case as one of large aneurism. He remembered the case alluded to by Dr. Johnston and thought the present very similar. The extensive dullness would be explained by the size of the aneurism and also by some pleuritic effusion, which he looked upon as slight in amount. That there was some effusion he judged from the enlargement of the right side of the chest, as aneurisms per se do not produce such enlargement. The lung was yet to a certain extent permeable by air for the swelling rose and fell on inspiration and expiration as if swelled by the lung on inspiration and allowed to subside on expiration.

He considered the seat of origin of the aneurism to be between the point of escape of the aorta from the heart, and its arch, for where it seated higher up, it would give rise to bronchial irritation from pressure on the bronchi.

If seated lower, near the heart, it would produce derangement of the aortic valves, the aortic patency so common in aneurism close to the heart. These signs were wanting in the case.

The history shewed severe shooting pains down the back and up to the shoulder at its early stages from pressure on the vertebræ. At present the patient complains of stomach pain around chest and waist from pressure on intercostal nerves, and of pain on pressure on the whole anterior part of the right chest indicating that the mischief has extended to the tissues of the anterior wall of the thorax.

J. Creery Ferguson, President

Pathological Room

February 28th, 1863

Present, the President in the chair, Drs. Thomas Reade, Dill, Patterson, Johnston, McCrea, MacCormac, McCourt, McWilliam, Gribbin, Smith, D. Moore, Staff Surgeon Saunders and Mr. Poppelwell (Assistant Surgeon).

The minutes of the previous meeting having been read and confirmed, Dr. Browne introduced a patient in whom he had performed Holt's operation for the relief of urethral stricture, a few days before. He was now able to introduce easily a number twelve catheter.

Staff Surgeon Saunders said the operation where performed had always proved satisfactory as far as he was aware. It was unnecessary to retain a catheter in the canal. Mr. Holt objected to its being done. As to rupture of the mucous membrane it was questionable if it occurred in every instance, the only part ruptured would be that situate within the extent of the stricture itself. The rupture would extend no further unless the dilator were too large in calibre for the canal. The operation had the recommendations of being simple in character, and free from hæmorrhage, or infiltration of urine as far as the cases yet recorded could shew. He hoped the unsuccessful cases would be duly reported as otherwise the true value of the operation could not be ascertained.

Dr. W. MacCormac thought it almost impossible for the membrane to remain unruptured under the sudden extension. At first sight the operation would seem a dangerous one. Dr. McNamara of Dublin had operated in forty cases and save in one, there were no symptoms or urinary fever. Mr. Stapleton of Dublin had failed in one case. The danger lay in the conversion of an ordinary stricture into a traumatic one which was the case in this operation. A few months only had passed since the operation was first recorded, and the period was as yet too early to set the cases down as entirely successful in which it has been done.

Staff Surgeon Saunders said much of the success depended on the after-treatment. A catheter must be passed regularly each week for a month, then once a month and subsequently every two months till cure is complete.

Dr. Browne considered the more recent cases of stricture were those suitable for Holt's operation, here the stricture was less firm, softer and more readily split, and the mucous membrane more safe and not so liable to be ruptured as in cases of old hard cartilaginous strictures in which latter class of cases the membrane may be ruptured.

Dr. Johnston thought that the gradual dilatation of this stricture would yield a more permanent cure than its sudden rupture. He would expect a worse contraction than the first would occur afterwards.

Dr. McCrea thought Dr. Johnston's remarks consonant

with the principles of surgery, the old plan of gradual dilation was used on the principle of absorption of the effused lymph being induced. He could not understand how after the sudden dilatation lymph would not be effused and the contraction occur again. Sudden symptoms of the stricture might succeed in two ways; first by rupture of muscular fibres if the stricture was cause of their contraction. Secondly by rupture of the old and hardened lymph in the latter case the liability to the continuity of the stricture being renewed would exist, and hence a considerable time must be permitted to elapse before we could pronounce that there was no tendency to contraction again.

Dr. Browne said that after the operation the catheter was used for some time to prevent re-contraction, but that the advantage of the operation consisted in the facility with which a large instrument could be passed at once afterwards, thus procuring at once what would require perhaps months to effect by the plan of gradual dilatation, a great saving of time, of suffering and anxiety to the patient, and also of the risk attendant on catheterism during those spasmodic attacks of retention which are so liable to attack persons labouring under stricture on exposure to cold and wet, or during excesses of any kind.

Dr. W. MacCormac considered Mr. Holt's operation more suited for old and hard strictures than for the more recent, which was readily curable by the old method. It was in the former class of cases that Mr. Holt himself recommended this plan. Mr. Smylie's modification did away with the objection that it was necessary first to pass a No. 2 or 3 catheter before Holt's operation could be performed, the modification consisted in a No. 1 or No. $\frac{1}{2}$ elastic catheter with a stilette over which on being passed through the stricture the elastic catheter was withdrawn leaving the stilette which now served as a guiding-rod over which silver instruments of small size could be passed till the stricture was sufficiently dilated to permit the passage of the dilator.

Dr. T. Reade said in many cases of stricture the process of gradual dilatation was a very slow one. In these the apparatus in the hands of an operator who was thoroughly conversant with the anatomy of the urethra and of experience in dealing with stricture would prove useful. Experience so far was favourable to it. He would caution all junior practitioners against the least haste in dealing with the urethra, an organ which required the utmost care and delicacy of touch in the manipulation of instruments passed into it.

The President remarked that as to the pathology of stricture, there were few membranous tissues that would admit of greater dilatation than the mucous. In the forcible dilatation the adventitious deposit of lymph would be ruptured, but he would not expect the mucous membrane to be ruptured also, at least

generally. He considered that the healing up of the adventitious tissue would be followed by its absorption and not by an increase of the deposit, any tendency to which would be obviated by the subsequent passage of an instrument.

Dr. Browne exhibited a specimen of a fibrous tumour removed from the lower part of the front abdominal wall of a middle aged male patient. When six years old he was bitten by a horse immediately over the pubis. The wound healed and in its site when a boy a small tumour presented itself of the size of a marble. It increased slowly, never larger than a small egg until eighteen months since when it rapidly began to increase in size and lately to ulcerate at two points. When removed the tumour was of the size of a small coconut. It was subcutaneous and easily removed on the skin being cut through, from the cavity of its attachment to the surrounding parts. Its texture was fibrous, presenting at some points the character of the recurrent fibroid tumour and it would be likely to return.

Dr. T. Reade said he had some years ago a case of a large tumour in a child two years old, in which he had been much deceived as to the facility with which the tumour would be evolved. Mr. Smylie of Dublin saw the case with him and stated as his opinion that the mass on incision through the skin would easily enucleate.

J. Creery Ferguson, President

Pathological Room March 7th, 1863

Present, the President in the chair, Drs. Stewart, Patterson, Reade, McGee, Graves, Cuming, McWilliam, Whitaker, Gribbin, D. Moore, Staff Surgeon Saunders, Mr. Poppelwell.

The minutes of the previous meeting have been read and confirmed, Dr. William MacCormac's motion, "That a sum of £5.5.0 be paid to Lewis of London for a supply of books during the ensuing year on loan to the Society" was discussed when it was resolved, That the matter be entrusted to the Council to make due enquiry and conclude such negotiation as may seem right.

The President brought forward a patient presenting a difficulty of diagnosis and asked for the opinion of the members of the Society upon it.

Dr. T. Reade asked were there any circumstances in the case which would give rise to any objection to the diagnosis, aortic aneurism. The case seemed to him obscure, as far as he could judge from the imperfect means of examination, and he would like to hear the President's opinion of the case before the members of the Society would state their individual views.

The President said that a case of aortic aneurism at least to his mind had been before the Society at last meeting. There, there was a pulsating tumour in the

right chest localising the mischief. In this case before the Society at present, there was no tumour observable anywhere. The sounds of the heart diminished in intensity either upwards or downwards from the base of the heart. The heart was enormously enlarged, with permanent patency of the aortic valves, patency due to an aneurismal dilatation of the artery separating the valves, which might be perfect per se, from each other.

He looked upon the case then as one in which there was a great enlargement of the aortic arch so large as to give rise to permanent patency and an occasional bruit with a first sound. The dilated arch pressed the innominate upwards and partially prevented the entrance of blood into it.

The heart was an example of hypertrophy with dilatation, the latter very great, the former but trifling. The heart sounds could be heard in the left back which was the case only when dilatation existed.

The point of dullness on percussion at the right side of the sternum was defined and there was no impulse there.

Dr. McGee did not consider the pulse presented at the wrist the peculiar undulation of that of aortic patency.

Dr. Graves said the case was a difficult and interesting one. From the imperfect access he possessed of making a careful examination he should think the case one of enlarged heart, with a tumour of some sort, he would not say what, pressing on the circulation of the right side.

The President said he had never met with a case in which he considered the peculiar pulse of aortic regurgitation better marked, sometimes amounting to *frémissement cataire*. He did not consider the aortic arch was equally engaged. There was no solid tumour connected with it. There was no cough, dyspnoea or dysphagia to lead to such an inference.

Dr. Cuming thought that the cause of the obstructed circulation might be found in the vessel itself. Patency so marked would argue disease in the valves and a portion of the fibrous vegetation having become detached would give rise to the obstruction.

Staff Surgeon Saunders

Pathological Room

March 14, 1863

Present, the President in the chair, Drs. Stewart, Patterson, Dill, Cuming, McCrea, Gribbin, McWilliam, Little, D. Moore.

The minutes of the previous meeting having been read and confirmed, Dr. McCrea gave notice of the following motion, "That the Secretaries be instructed to disavow the account of the supper of the Ulster Medical Society, so called, as it appeared in the daily papers recently."

[This may be the report complained of:¹

The Belfast Medical Society and the Royal Marriage.—March 10 being the festival of the marriage of the Prince of Wales and the Princess Alexandra, the members of the Ulster Medical Society supped in their rooms, High Street, to inaugurate the auspicious event. The President, Professor Ferguson, occupied the chair. The usual loyal toasts being disposed of, "The Health of the Prince of Wales and the Princess Alexandra of Denmark" was then given. Dr. Pirrie responded to this toast. He contrasted the conduct of the present Prince of Wales compared to his predecessor, and asserted that, owing to the good management of his father, the late Prince Albert, the country had been saved to the extent of about £50,000 per annum. He hoped they would live long and be happy, and be blessed with a numerous progeny. "The Constitution." Dr. Michael M'Gee eloquently dwelt upon the advantages arising from a good sound education. He expatiated at some length on the benefits arising to society by having the mass of the people educated, and eulogized the form of Government we live under. "Medical Education." Professor Gordon spoke to this toast. He was proud to say that the medical standard of education had been raised to such a height that no person could be a legally qualified practitioner unless he was educated, and that the Government deserved the thanks of the community for passing an Act making it incumbent for the medical man to be registered, so that the scholar and the man of science could be known from the quack and the impostor. Dr. Smith then proposed "The Health of the Secretaries, Drs. David Moore and Whitaker," who, in brief and humorous speeches, returned thanks for the compliments passed on them. "The Health of Dr. Patterson." This gentleman, who has always been so active and zealous member in every movement where the honour and dignity of the profession required his services, returned thanks in a very feeling and efficient speech. "The Health of Drs. Beck and Cuming" being then given, Dr. Patterson alluded to the papers brought forward by those gentlemen before the society, and complimented them on the active parts they had taken in the discussions, and their zeal and attention to the workings of the society. The President then give "The Junior Members." Dr. Gribben, at the general request of the meeting, spoke to this sentiment briefly, but in eloquent and appropriate language. The meeting broke up at a late hour, all having passed off in a most satisfactory manner.]

Dr. Little of Lurgan exhibited a diseased testis which six weeks ago he had removed from an infant, 14 months old. The child who 4 months ago had received an injury of the testis; from the mother's account by having come forcibly in contact with the crinoline of

¹ [Northern Whig, Saturday 14 March 1863.]

the nurse. The testicle slowly and steadily increased in size in spite of the remedies employed—iodine, strapping etc. By and by the health began to suffer and as a collection of serum had formed at the bottom of the tunica vaginalis, below the tumour, it was drawn off by the trocar. The relief of the tension so produced diminished the restlessness and feverishness of the child for the time, but as they returned after a few days and continued well marked, Dr. Little considered the removal of the testicle would afford a chance of a favourable issue, while on the other hand were it permitted to remain the result was certain to be unfavourable. Accordingly, six weeks ago, the tumour was removed, and the child improved in health after the removal till the tenth day when it became feverish, refused its food and had tenderness of abdomen. Diarrhoea set in, tympanites, and on the sixteenth day, death.

Dr. Little remarked that the case determined a point of which he was previously uncertain, namely, whether or not a child of so early an age as 14 months could recover from a serious operation. He looked upon the operation as a serious one in this case as the tumour was of the size of a small orange, yet the child did well apparently for ten days after the operation. He wished for the opinion of the Society in the case.

The President said that from the history of the case he should consider the course run by it was not altogether that occurring when abdominal disease was unsuspected before the operation. That death was due to peritonitis, perhaps subacute at first, from inflammation extending along the track of the operation, and engaging at length the peritoneum. The history was not like that of ulceration and perforation of the intestine, as death would then occur much more suddenly and supervene more immediately with early symptoms of peritoneal inflammation. The tumour consisted of tubercular deposits in the testicle.

Dr. Little said that no doubt a mesentery studded with tubercular deposits would be more liable to inflammation than a healthy one but if the inflammation extended from the wound, he would expect it to make its appearance before ten days had elapsed. He should think that if inflammation were to follow the operation in such a case as the present, the time of its appearance would be the same as in cases of hernia, on the second or third day, and that period passed he should conclude the patient comparatively safe. As to whether the removal of such a tumour would increase or aggravate the tendency to deposit in other organs of the body he should like to hear.

Dr. Cuming remarked that in strumous diatheses there was a marked tendency to the development of phthisis after surgical operation for the removal of diseased joints, etc., and that cases in which the chest affection is only slightly marked will frequently be hurried into rapid phthisis if operative interference

with a diseased joint, for example, has been practiced, and quoted a case falling within his own knowledge in which a young person in whom the chest symptoms were so slightly marked as to give rise to a difference of opinion on the subject between two medical men, had yet succumbed to a rapid phthisis following a surgical operation on a strumous joint, and that in so short a period as five weeks. In the case at present before the Society, a child of tender age might readily sink from so large a development of tubercular matter in one organ as had probably occurred judging from the morbid specimen at present under our notice, and this in so tender an organ as the peritoneum.

The President said he would however be slow to accept the idea that a child, in the case of strumous deposit in the abdomen, would die in six days from acute inflammatory action.

J. Creery Ferguson, President

Pathological Room

March 21, 1863

Present, the President in the chair, Drs. Stewart, Patterson, Michael McGee, Cuming, Gribbin, Corry, McCrea, W. MacCormac, McWilliam, Beck, Whitaker, D. Moore.

The minutes of the previous meeting having been read and confirmed, the following report from the Council was read and approved of. "That having written to Messrs. Lewis and Knipton of London, and Mr. Fannon of Dublin for information regarding their Libraries and having received communications from each of them, the Council have entered into arrangements with Messrs. Lewis for a regular supply of books to the Reading Rooms for one year."

Dr. McCrea then brought forward the motion which was seconded by Dr. McWilliam, "That the Secretaries be instructed to disavow the report of the supper of the Ulster Medical Society, so called, as it appeared lately in two of the daily papers." After some discussion the following amendment was proposed by Dr. Patterson, seconded by Dr. William MacCormac, and passed viz "That the Society recommend that no reports of any entertainments given by the members be published in the newspapers unless through the Secretaries, and that it disapproves of the publication of the report of the supper of the 10th instant."

J. C. Ferguson, President

Pathological Room

March 28th, 1863

Present, the President in the chair, Drs. Patterson, Pirrie, Gordon, Gribbin, McCrea, McWilliam, W. MacCormac, Whitaker, D. Moore.

The minutes of the previous meeting having been read and confirmed, Dr. Gordon exhibited a specimen of hypertrophy of the fang of a tooth, and stated the facts in connection with the case.

Dr. Gordon exhibited a specimen of “chronic mammary tumour” recently removed from the breast of a female of 29 years of age, and read notes of the case. Dr. Gordon read notes of a case in which amputation had been performed for compression and dislocation of the ankle joint, and exhibited the removed part.

Samuel Browne V.P. Chairman

Pathological Room

April 4, 1863

Present, Dr. Browne V.P. Chair, Drs. Stewart, Dill, Patterson, McCrea, Arnold, McWilliam, Gribbin.

The minutes of the previous meeting having been read and confirmed, the Secretary stated that the report from the Council embodying the rules drawn up in reference to the books from time to time received from Lewis’ Lending Library, would be laid before the Society at next meeting. Dr. Browne then exhibited a specimen of diseased knee joint for which amputation had been performed in the lower third of the thigh, and stated the facts in connection with the case.

Dr. Dill asked if in this case there were any circumstances which obviated the adoption of treatment to produce ankylosis of the joint. He considered that at a certain stage of the disease all cases should be treated with a view to ankylosis. Within the present year one case in particular had come under his notice, that of a man who had been dismissed from the County Infirmary as he would not submit to amputation for the removal of a diseased knee joint. He was admitted subsequently into this hospital under the care of Dr. Murney, and the result was an ankylosis of the joint with a firm serviceable limb. The man was a butcher by trade and could be seen daily in Hercules Street walking about in the pursuit of his business.

Dr. Browne stated that when his patient was admitted to hospital the disorganisation of the joint and disease of the articular ends of the bones had proceeded too far to admit of ankylosis. Whilst performing the amputation, the incision made passed through large abscesses in the muscular tissue of the thigh communicating with knee joint.

Dr. Browne then in the absence of Dr. Gordon exhibited a specimen of diseased knee joint for which amputation of the thigh had been performed by Dr. Gordon, and stated the facts in connection with the case.

J. Creery Ferguson, President

Pathological Room

April 11, 1863

Present, the President in the chair, Drs. Stewart, Patterson, Dill, McCrea, Beck, Gribbin, D. Moore, W. MacCormac.

The minutes of the previous meeting having been read and confirmed, Dr. Beck exhibited a variety of different-sized instruments which he had from time

to time devised, as occasion occurred, for the removal of foreign bodies from the different passages—the nares, ear, rectum, vagina, œsophagus etc., and stated cases in which they had severally been successfully used.

Dr. W. MacCormac then laid the following rules to regulate the circulation of the books received from Lewis’ Lending Library before the Society—viz

Rule 1. The Secretary shall order fourteen volumes at a time, to be renewed every three months, the date of ordering to vary should the Council deem it expedient.

Rule 2. The Books, before being issued in circulation, are to lie one week on the Table of the Society for the inspection of the members.

Rule 3. Members may have one volume at a time for a period not exceeding two weeks. A penalty of three pence per day will be exacted from any member retaining a work, without renewal for a longer period. The loan may be renewed at the termination of the specified time if no member had applied for the work.

Rule 4. Any member losing or injuring a work will be required to replace or pay for it.

Rule 5. A member wishing to read a particular work can have it ordered by inserting the name in a proposal book to be provided for the purpose. Should the number of volumes inscribed exceed fourteen the Council shall have the power of selecting which books should be ordered.

Rule 6. Members will receive the Books in the order in which their names may be written down. The member, who in accordance with Rule 5, has requested a Book to be ordered shall always be entitled to the first perusal of the work.

Rule 7. No member may have his name inscribed for more than three volumes at a time.

Rule 8. A list of the works which have been ordered is to be placed in a conspicuous part of the Society’s rooms.

Rule 9. Should any book be allowed to lie on the table for three days without being claimed, the member whose name appears next on the list may have the work on applying to the Secretary.

James Patterson

Pathological Room

April 18, 1863

Present, Dr. Patterson in the chair, Drs. Browne, Dill, Staff Surgeon Saunders, Gribbin, McWilliam, W. MacCormac, D. Moore, Stewart.

The minutes of the previous meeting having been read and confirmed, Dr. Browne read the history of a case of fibrous tumour of the uterus terminating fatally after pregnancy.

Dr. Dill asked if in the progress of the case any other course could have been pursued than that

adopted, and if the induction of premature labour would not have been advisable.

Dr. Browne said the question of induction of premature labour would not have escaped attention, had not the patient been from under observation from the 12th May till the 21st September last at which latter period the time for such interference had gone by.

J. Creery Ferguson, President

Pathological Room

April 25, 1863

Present, the President in the chair, Drs. Stewart, Patterson, Browne, Dill, McWilliam, Arnold, McCrea, Gribbin, Mr. Johnston, Drs. Whitaker, D. Moore.

The minutes of the previous meeting having read and confirmed, Dr. Browne read notes of a case of urethral stricture, in which "Holt's operation" by sudden dilatation had been performed. Dr. Browne remarked that the experience of this case, with that of the case previously brought before the Society, confirmed the view he had entertained that there was no fear of contraction of the parts ruptured following the operation.

Dr. Browne then read notes of a case of traumatic tetanus in which the issue had been favourable, and stated his belief that recovery was due more to the "vis medicatrix" than to the means employed by Art.

Dr. Dill shewed a portion of an umbilical cord of a foetus, which had arrived at the full period of gestation, on which a knot had been formed in utero.

James Patterson, President

Annual Meeting

2nd May, 1863

Present, Dr. J. C. Ferguson (President, in the chair), Drs. Scott (Aughnacloy), Dill, McWilliam, McCrea, Rankin (Kircubbin), Cuming, Patterson, Moore, William MacCormac, Wheeler, Gribbin, Arnold, Murray, John Smyth, James W. Smith, David Moore, and Whitaker.

The minutes of last meeting (annual) were read and confirmed.

The report from Council for the past year was then read, received and confirmed.

The Treasurers report was received and adopted.

The election of officers for the ensuing year was then proceeded with by ballot when the following gentleman were duly elected.

President

Dr. Patterson

Vice President (town)

Dr. J. S. Reid

do (country)

Drs. Scott (Aughnacloy) and Little (Lurgan)

Council

Drs. Arnold, Cuming, Mr. Gribbin,

Drs. MacCormac (W.), McCrea, and Mr. James

Smyth

Treasurer

Dr. J. W. Smith

Secretaries

Drs. D. Moore and Whitaker

Dr. Moore (D.) resigned the office of Secretary.

Dr. Dill handed in the following notice of motion, "That it be not necessary, in future to pay the annual subscription before taking part in the May meeting."

Votes of thanks were passed to the outgoing President, Treasurer and Secretary which were suitably acknowledged.

James Patterson

ULSTER MEDICAL SOCIETY

SESSION 1863–64

Monthly Meeting

June 6th, 1863

Present, Drs. Patterson (President, in the chair), Cuming, MacCormac, Gribbin, Arnold, McCrea, Burden H., McWilliam, Beck, Reade, Moore D.

The minutes of last meeting having been read, it was moved and seconded, "That they be confirmed."

Amendment moved and seconded "Dr. Dill's name be expunged from the list of Vice Presidents, in consequence of his not having been legally elected by a majority of votes as required by the rules of the Society." Amendment put and carried.

A letter was read from Dr. Reade resigning the office of Vice President and thanking the Society for their kindness in electing him.

Dr. Reade's resignation was accepted.

A letter was read from Dr. Dill resigning the office of Vice President.

The President then left the Chair which was taken by Dr. Arnold.

Dr. Reid was elected Vice President, Dr. McCrea Secretary in room of Dr. D. Moore and Dr. H. Burden Member of Council.

Dr. W. MacCormac then read an interesting paper on M. Baradue's theory of the causation of death in cases of severe burns.

Dr. Beck remarked that he had seen a case in which no vesicles had formed and which he did not think the shock was sufficient to cause death although the patient sank rapidly.

Dr. H. Burden thought that M. Baradue's line of practice was founded on insufficient data; in cases of eczema there was a great exudation of fluid yet fatal results did not occur.

Dr. W. MacCormac remarked that in cases of eczema there was not a rapid abstraction of fluid as in burns.

Dr. Arnold thought that M. Baradue paid to little attention to the shock attendant on severe burns.

Dr. D. Moore thought that the shock to the nervous system and the acute prostration consequent thereon, were the principal causes of a fatal result in cases where such occurred.

James Patterson, President

July 4th, 1863

Present, Dr. Patterson, President in the chair, Drs. Ferguson, Wheeler, MacCormac William, McWilliam, Smyth, Brice, Gribbin, Burden H., Smith J. W., Warwick, Grattan T., and Whitaker.

The minutes of last meeting having been read and confirmed, Dr. Pirrie was elected Vice President of the Society.

Dr. H. Burden read notes of a case of midwifery in which turning was much facilitated by the use of a simple instrument which was exhibited by Dr. Burden and its mode of application explained. This instrument had been contrived by Professor Burden some 12 years ago and in his hands had also been found to answer the purpose for which it was intended.

A conversation ensued in which most of the members joined, and expressed their approval of the views expressed by Dr. Burden, though some suggested that an instrument almost similar had been seen by them many years previously to its construction by Professor Burden.

James Patterson, President

August 1st, 1863

Present, Drs. Patterson (President in the chair), Arnold, Reade, Smith, James, McWilliam, McCrea, Gribbin, Burden H., and Whitaker.

The minutes of last meeting having been read and confirmed, the proposal to add to the library "Lawrence's Lectures on Surgery" and "Syme's Observations on Surgery" fell to the ground, owing to the absence of the proposer and seconder of these books.

It was then moved and seconded, "That 'The Times' be substituted for 'The Daily Telegraph' in the new room." A desultory conversation ensued in which most of the members joined; after which the proposal was unanimously agreed to.

James Patterson, President

Special Meeting

September 4th, 1863

Present, Drs. Reade (Chair), Ferguson J. C., Ferguson H. S., Moore James, Cuming, Patterson, Keown, McCrea, Rankin, Gribbin, McGee Michael, MacCormac William, and Whitaker.

"Summoned by special requisition of Council" to consider the propriety of entertaining the Medical Officers of the Channel Fleet. Dr. Reade (Thomas), in the absence of the President, having taken the chair called upon the Secretary (Dr. Whitaker) to state the circumstances under which the meeting was summoned and whether any and if so what steps had been taken in the matter.

Dr. Whitaker having briefly stated the facts of the case and that no steps had as yet been taken in the matter, expressed his regret at the absence of the President with whom the idea had originated and who would, had he been present, have given the Society his views on the subject.

Dr. McCrea objected to the Society taking any part in the contemplated dinner, and thought that it would be better to let the matter drop.

Dr. Michael McGee strongly supported Dr. McCrea.

Dr. James Moore thought that it was only proper that the members of the Society as such should shew proper courtesy to their brethren of the Navy and in no way he thought, could it be better done than by inviting them to dinner.

The President having entered the room, took the chair, and having apologised for his unavoidable absence stated fully his views and expressed his opinion in favour of the proposed dinner.

Dr. T. Reade proposed and Dr. Moore seconded and on a division it was resolved "That the Medical Officers of the Channel Fleet be invited to dinner on their approaching visit."

James Patterson, President

Dinner to the Medical Officers of the Channel Fleet by the Ulster Medical Society.¹

On the 10th inst., at seven o'clock, the members of the Ulster Medical Society entertained their brethren of the vessels comprising the Channel Fleet to a dinner in the Society rooms, High-street. There were between thirty and forty members of the Association present. Dr. Patterson, the President of the Society, occupied the chair; and Drs. Wm. McGee, J.P., Reade, and J. Moore acted as croupiers.

There were present at the dinner—Dr. Andrews, Vice-President Queen's College; Dr. McGee, J.P.; Dr. Moore, Dr. Browne, R.N.; Dr. McMechan, Dr. Keown, R.N.; Dr. Wheeler, Dr. Mulholland, Dr. A. H. Cooke, Royal Antrim Artillery; Dr. Stewart, Dr. Henry Ferguson, Dr. Patrick, Carrickfergus; Dr. Gribben, Dr. McCormac, jun.; Dr. David Moore, Dr. Dundee, Carrmoney; Dr. Whittaker, Dr. Hanna, and Dr. Lytle, Lurgan. The guests were—Dr. Anderson, 60th Regiment; Dr. Bayfield and Dr. Popplewell, 14th Depot Battalion, and the Medical Officers of the Fleet. Apologies were received from Dr. Stephenson, Dr. Drennan, Dr. Clarke, Dunmurry; and Dr. Kennedy, Comber.

The Chairman proposed "The health of the Queen," which was drunk with enthusiasm.

The Chairman said the next toast he had to propose was that of "The Prince and Princess of Wales."

The toast was received with hearty applause.

The Chairman next proposed "The Lord Lieutenant and Prosperity to Ireland," which was enthusiastically received.

The Chairman said the next toast on his list was, although not the principal toast of the evening, something similar to it. It was essential on all such occasions as the present to propose the toast of "The Army and Navy," which he did with a hearty good will.

Dr. Cunningham of the 60th Regiment responded on behalf of the army, and he was sorry to say that he happened to be the senior member of the medical staff of

the Belfast garrison present on that occasion. It was owing to the exertions of the Medical Society of Ulster that they had attained their present position in the army, and he was sure he might be allowed to say that he had heard his native town of Belfast spoken of as one of the foremost towns in which a soldier could live, and where he would meet with kindness and sincere hospitality (applause).

Dr. McGee, J.P., responded on behalf of the navy.

The Chairman—Gentlemen, I have now the most pleasing duty to perform, and I am sure you will all most cordially join with me by filling a bumper to the toast I am now about to propose (hear). The presence of the Channel Fleet in the waters of our Lough naturally suggests to our minds how deeply we are indebted for the freedom we enjoy to the unconquerable bravery which has ever characterized the British Navy. If we possess all those constitutional blessings which give stability to a state by rendering its citizens secure in the enjoyment of those rights and privileges, must we not admit that, amongst other agencies at work, the British Navy has been most potent—has most nobly contributed by its illustrious services, to confer those inestimable blessings, and I will say, to secure them to us (applause). Gentlemen, we must all feel proud in honouring that flag which has triumphantly braved for "a thousand years the battle and the breeze" (hear). We identify ourselves with its glory—we rejoice in its principles—we honour its renown—we regard it as the best safeguard against a foreign foe, to protect what is Great Britain's boast, "happy homes and altars free" (applause). When we consider the extent of the dominions ruled over by our gracious Queen, upon which the sun is never privileged to set—the magnitude of the trade connected with our colonial establishments—we cannot fail to see the mighty interests which are involved in our retaining, at all hazards, the proud empire we have so gallantly won—the supremacy of the seas. In this I am sure we are all agreed, and it is most agreeable to my feelings to give expression to sentiments in which I know you all so heartily concur. Gentlemen, it is our peculiar privilege on this occasion to have amongst us guests who have always with zeal and fidelity shared in its dangers, though I must say they have not equally participated, as their merits entitled them to, in the rewards. It would not be seasonable, on a festive occasion like this, to enter upon professional grievances. Recently considerable ameliorations have been effected, and I do hope that the Government will soon grant full justice to our brethren in the service, justice to which their education, their zeal, and fidelity preëminently entitle them. But, gentlemen I will not detain you longer. I know you all feel as I do, anxious to do honour to our guests; and I will manifest my anxiety to honour them by refraining from any further observations, and calling on all of you to join me in a hearty response to the health of the "Officers of the Channel Fleet," who

¹ [Dublin Medical Press, 1863, September 16, p378.]

Ulster Medical Society
Session 1863–1864
President James Patterson

have honoured us with their company this evening.

The toast was drunk with “three times three.”

Dr. Sloggett, of her Majesty’s ship Edgar, said that, in the absence of the senior medical officer of the squadron, the duty devolved upon him to reply to the toast which had been so kindly received by the company present. He only regretted that he was not enabled to do full justice to the sentiment; but he hoped they would forgive him (hear). The professional gentlemen of the navy felt acutely the want and the advantage which their brethren enjoyed on shore. He alluded to the professional meetings such as were held by the Ulster Medical Society. After some remarks on professional matters, in which Dr. Sloggett stated that there were yet many means open for improvement in the medical service of the navy, he concluded by thanking the meeting for the kind manner in which the toast had been received (loud applause).

Dr. Smyth, of H.M.S. Royal Oak, next proposed the toast of “The Ulster Medical Society,” coupling with it the name of Dr. Patterson, the President.

Dr. Patterson returned thanks. He regretted that on this occasion there was not a larger number of medical practitioners present. The ball which took place that evening had prevented a few members from attending; but still they were glad to have an opportunity of welcoming the medical officers of the Channel Fleet, and also the medical officers of the garrison. He hoped if the Channel Fleet would again visit Belfast two or three years hence that there would be a meeting of the medical profession, which would not only fill the room in which they were at present assembled, but would fill the Minor-room of the Ulster Hall (applause). He begged to thank them for the kind manner in which the toast had been received.

The toast of “The Press” having been proposed and responded to, the company separated.—Northern Whig.

October 3rd, 1863

Present, Drs. Patterson (Chair), Ferguson, Stewart, William MacCormac, Smyth.

Dr. Stewart moved, and Dr. J. C. Ferguson seconded, “That the annual address of the President and dinner thereafter be held on the first Tuesday in November.” (the 3rd)

Society’s Rooms

November 3rd, 1863

Present, Drs. Patterson, Ferguson, MacCormac (William), Wheeler, Keown, Arnold, McGee (Michael), Cuming, Dill, Gribbin, Browne, Whitaker, Saunders.

The President then delivered his opening address. He shewed that the interests of the public and the profession are identical. He regretted that more members of the profession did not join the Society. He referred to the great progress of the profession during the present century, and referred to Registra-

tion Act. He insisted on the necessity of preliminary education.

He deprecated the small remuneration which medical men received in the country. He expressed an opinion that any great change must come through the profession itself. He disclaimed the idea of a new Act, and recommended pressure on the Medical Council. He pointed out that corrections ought to be made in the Medical Register, and shewed some discrepancies between it and the Medical Directory. He mentioned several cases shewing the difficulties in the way of correct Registration.

He recommended uniformity of education and examination and referred to the great change for the better that already occurred. He alluded to the vexed question of the admission of reporters; and proposed a compromise, that the Council should publicise a digest of their proceedings.

Paper:¹ GENTLEMEN, I cannot proceed with the few observations which it is my duty to address to you on the opening of the second session of the Ulster Medical Society, without sincerely expressing how sensible I am of your kindness in electing me to the honourable position of your President. I appreciate highly, indeed, the honour you have conferred on me, the more so, as it was entirely unanticipated on my part; but I accept it, and feel gratified for it, as an evidence of kindly feeling, both personally and professionally, on your part, which it shall always be my pride and happiness to cultivate and cherish.

I certainly have taken a warm and anxious interest in the re-construction of the Medical Society on its present basis, and I shall always deem it a privilege to coöperate with my brethren in rendering its organization more perfect and in extending its sphere of usefulness, so that it may become what we all earnestly desire to make it—an institution worthy in all respects to represent the profession in Ulster. It is indeed with pleasurable feelings that I can congratulate you on the progress the Society has made, and on the position to which it has already attained.

It is indeed true, that, in glancing over the list of members we find many omissions,—the names of many gentlemen, in town and country, are, I may say, “remarkable for their absence;” still, I doubt not, when our objects are better known—our motives in associating together better understood—that our Society will be more truly appreciated and supported.

In fact, Gentlemen, for what are we labouring? for what purposes do we assemble here? Are they not the most laudable—the interests of our noble profession, and, therefore, the interests of the public. We pursue no mere selfish objects, and I identify the interests of the

¹ [An Address delivered at the Second Annual Meeting of The Ulster Medical Society, November 3, 1863. By the President, James Patterson, M.D., Edin. Booklet printed by Alex. Mayne, High Street. 1863.]

public with the interests of our profession, because I emphatically hold that, rightly understood, both interests are the same. In ages of comparative ignorance and darkness, when medical knowledge was in its infancy, enthralled by superstition, and struggling to attain an intellectual existence, who, I ask, were the greatest sufferers? Why, the public at large. And now that medical knowledge has attained a position we have just reason to be proud of—now that crude theories have been sifted by experience, and ascertained knowledge systematized into a science, the onward progress of which has been along an illuminated path, each succeeding stage becoming more brilliant, though the wayside has been too frequently bestrewed with martyrs—now, I ask, when in this age, superlative for its genius on almost every subject, medical men occupy the foremost rank, and medical science is cultivated with the most distinguished success, who are the greatest gainers? Why, I answer, the public at large. This is what I wish was better understood. If the public reflected for a moment, this truth would be irresistible. By patient study, by laborious practice, by profound researches we can acquire no knowledge which does not directly tend to the public advantage. In fact, no profession is more prominently absolved from the charge of the pursuit of selfish interests than ours is, because all our efforts to uphold professional interests, in like manner as all our studies, have but one object in view—to render our services more useful and valuable to the public.

It is this consideration which must free us from any imputation that in associating together we have mere selfish ends in view. We legitimately avail ourselves of the principle of association, which is a distinguishing feature of our age, because by no other means could the laudable objects we contemplate be so efficiently promoted. A unit is of little avail, but in combination units become all-powerful. Individually, professional men, scattered over the country, have few opportunities of imparting, *viva voce*, their experiences to their brethren, or of aiding in sustaining professional interests. Our Society is designed to supply this great want. We associate together for mutual improvement, such as always must follow a free interchange of ideas and experiences. In our social principles and relations reside the great springs of improvement, the stimulants to vigorous and efficient exertion. The healthy impulses and influences to be derived therefrom we desire to render available, and, therefore, our Society exists.

I would earnestly entreat our brethren who have not as yet joined us, to reflect a moment on their own position and on the advantages our Society offers. We can lose nothing, but gain vastly, by enlarging the sphere of our observations; at the same time, we have the gratifying knowledge that we are members of a Society—one great object of which, among others, is to uphold our profession in its true honour and dignity. These considerations, I sincerely trust, will induce the

profession generally throughout Ulster to join our Society, and thereby strengthen its powers of usefulness. By union we have already accomplished much that has proved most beneficial alike to the profession and the public; but a vast deal remains to be achieved.

While, however, I am indulging in fond anticipations respecting an accession of membership, I cannot but pause, with a sad feeling, to notice the loss we have sustained since we last assembled here. Two young and most promising members (Surgeon W. Hanna, and Dr. Greenfield of Holywood,) have been suddenly taken from among us, and there is too much reason to believe they fell martyrs to the faithful and fearless discharge of their professional duty; and therein consists their most honourable epitaph. When death walks the earth, it is the peculiar privilege and duty of medical science to arrest his progress and stay his footsteps. In this warfare our brethren have never yet been false to their profession and timidly shirked the post of duty because it was at the same time a post of danger. Under God's good Providence we all exist and labour, and under that all-abiding Providence it is incumbent on us to use the light of science and of experience in counteracting disease and casting back the shadow of death. Should we, in thus labouring, incur infectious diseases and receive the seeds of death, it is the penalty of our profession, and our best consolation will be found in the reflection, that we have been faithful in the fearless discharge of our duty.

This is a melancholy subject, Gentlemen, one that unhappily obtrudes itself too often in our daily avocations; and I will now revert to what I was alluding to before the thought of membership introduced it. I was endeavouring to show the manifold advantages to be derived from the association of professional brethren together in such a Society as this. In this age, little, indeed, is to be gained without such a union of individual means as association implies. To associated action we are indebted for all the beneficial changes that have been already effected respecting the status and interests of our profession. As an instance, allow me to refer to the Registration Act, not by any means a perfect work of legislation, but still containing much that is salutary, together with the germs of great future improvement.

At the beginning of this century, how many men practised throughout the United Kingdom, even in populous and wealthy districts, without any medical qualification whatever—how many without medical education at all! This state of things has been gradually changing, and there is ground for the expectation that it will one day become amongst the things which belong to history. I do not desire to represent the medical profession of our time as standing very far above that profession in the last century. It may be doubted if there are at present, throughout the empire, as many great physicians as there were in the several generations of

the last century. That is a question which it would not be easy to settle. But whatever may be the comparative merits of the heads of the profession in the contrasted periods, it is clearly beyond doubt that there is, at the present time, an infinitely greater proportion of well-educated, useful, skilful, trustworthy practitioners spread over the country than at any previous time.

Yet, the most ardent wishes are but our duty, both for the sake of the profession itself and for the benefit of the public, that this happy progress may continue to take place to a far greater extent than can yet be boasted of.

While, however, the signal improvements on the race of general practitioners throughout the country, in the past years of this century, is a subject for hearty congratulation, it must be confessed that that very improvement is fast destroying—at least in most parts of England—the old, most useful, and respectable order of country physicians. It is true that it was the imperfect qualifications of the general practitioners, in the country and in the smaller towns, that made the provincial physicians so necessary, and that it is hardly possible to regret the rise of that amount of skill, among general practitioners,—which has rendered the services of physicians out of our great cities less necessary. It was throughout England, chiefly, that this body of physicians was to be met in former times. In Ireland and Scotland they were more thinly scattered, and therefore, perhaps, less change in that respect is discoverable in these latter portions of the United Kingdom.

The decline of this body is not so much to be regretted on account of superior skill—it is to be regretted because they held all along a high social position, such as the general practitioner cannot always attain. There can be no doubt that the decline of this body of physicians impairs, somewhat, the progress which, in other respects, the medical profession is making towards a higher social position. The knowledge of this fact renders it the more incumbent to contribute what is in their power to forward this progress of the medical profession towards the position which it ought to hold in the social scale.

In the ardour of multifarious professional study, at the medical schools, it is sometimes forgotten how essential it is that men should possess such an amount of literature as is indispensable, in this country, to place one in a right social position. It is needless for the utilitarians to declaim against classical attainments—the law which, in our islands, exacts a knowledge of classical literature as the price of admission to the circle of the best society, is unalterable as that of the “Medes and Persians.” In short, the general diffusion of classical attainments, in the medical profession, is necessary to the complete usefulness of its skill in the art of healing to the public. Let the heads of our medical schools look to the matter in this light—let them give up weighing the utility of Greek and Latin to medical men in the

abstract—let them turn their attention simply to the greater usefulness awaiting the medical profession as a body in proportion as the whole members collectively rise in the scale of social life.

The chief difficulty which presents itself, opposing the general rise of the whole profession in the social scale, is the small remuneration to be obtained for professional services in the poorer districts of the country. How can we look for men of good preliminary education to engage in a profession which so often yields but a miserable pittance in return?

A classical education, even at a moderate cost, is within the reach of every one who is ambitious of entering the medical profession. It is not necessary that this kind of education should be profound, but it must be, at the very least, respectable—considerably greater than it averages at present throughout the profession.

It is of no use to debate whether this kind of accomplishment be the best fitted to make good surgeons or physicians, that is no part of the question. In my own opinion it forms the best preliminary we have, and it is certainly the kind of education which alone will have the effect here under consideration—namely, to raise the whole profession in its social condition.

Ignorance of literature is fatal to a man's pretensions, in this country, to gain a position in society. No man must be allowed to take up medicine or surgery without first showing his competency to study, not merely what is requisite for professional duties, but such subjects as fit him to hold a place among the educated of the land. If it could be proclaimed to the public that every regular member of the medical profession has proved himself both competent to study, and a proficient in study, how great would be the effect on the estimate of the character of the medical body!

Were all taint of the illiterate removed from the medical profession, a higher tone of feeling would of necessity succeed. There must be no quackery within the profession itself. The essential rules of medical etiquette must prevail. If ignorant quackery cannot be put down, it can be kept at arm's length. There must be no coquetry with the homœopaths.

To attain such a golden age as I am pointing at, there is little more requisite than a firm determination on the part of the profession itself. Little more can be got by legislation; what we have got has disappointed many, but those who are thus disappointed expected a great deal too much from this source.

Though the Medical Act has done little absolute good as yet, if the profession be resolute to compel its administration, there is in it much power for good. People are very apt to over-estimate the power of an Act of Parliament. During the long years which medical reform was in agitation, it seemed as if nothing was necessary but to get the various contending parties to agree on the clauses to be embodied in the Act, and that the Act, once passed, would determine things to run smoothly in

strict accordance with its stipulations.

Considering the sanguine ideas formerly entertained of the benefit to be derived from this Act, the whole matter seems to be a complete failure. But to those better versed in the nature of the difficulties which beset the medical profession, and in the complicated relations in which it is involved, the Medical Act appears in a brighter light, not, indeed, as an immediate cure for all the evils which were complained of, but as an instrument, by the patient employment of which a great amelioration may be finally accomplished. That end will be attained, not by seeking new powers from the legislature, but by a well-directed judicious pressure on the General Council from without by the profession, so as to aid that body to carry out such measures as are truly in the spirit of the Medical Act.

The Registration is in itself a mighty measure of medical reform. The value of an exact list of all the men throughout the United Kingdom who hold a legal qualification to practise can hardly be overrated. Compare this Register, issued by the authority of the General Medical Council, with the Medical Directory in its earlier editions. Why, in the Directory there was found every quack doctor, self-dubbed a physician or surgeon, who had boldness enough to impose on the publisher. Small as the corrections on the Register have been since its publication, it can be seen, by consulting the published minutes of the Council, how much trouble and expense has been required to accomplish even that little.

The case of Richard Organ should be known to the profession, as showing the difficulties which present themselves to the Council in the execution of the duty assigned to them. Richard Organ appears to have got his name placed on the Register by some inadvertence; he was afterwards detected in an attempt to get the license of the Edinburgh College of Physicians by personation—that is, by getting another person to appear in his stead. He was struck off the Register by the General Council, but, on application to the Court of Queen's Bench, the Council were required to show cause why his name should not be restored; that is, an action at law had to be sustained in behalf of the proceeding. The Council finally gained the suit. In the proceedings of the General Council, at their last meeting, it will be found that Organ had applied to the Society of Apothecaries, of London, to be examined for their license, and that the Society had sought the advice of the Council on that point—the advice given being, that his application should be refused.

In the same proceedings will be found five or six cases besides, illustrative of the difficulties attendant on the purification of the Register, and of the energy which the Council has shown in the execution of that part of their duty. It is in particular a subject for congratulation, that, at their last meeting, the Council erased from the Register the name of Samuel La'Mert,

on account of an indecent and unprofessional treatise, and falsely pretending that his son, a licentiate of the Edinburgh College of Physicians, was joint author of the same. By proceeding in this manner, it cannot be doubted but that a great purification of the profession will be accomplished.

It has been made a ground of complaint against the Council, that they do not institute proceedings against registered persons who contravene the provisions of the Medical Act, or against non-registered persons who assume medical titles without qualification. Their answer to the former part of this complaint is contained in a report published in the proceedings for 1859—namely, that their functions, in respect to accusations, are judicial, and that they cannot combine the office of accuser with that of judge; and further, that the Act does not empower them to assume the part of accusers.

With respect to the second part of the charge, it appears that the Council think the present Act defective, as they propose, in a Supplemental Act, to make the clauses against the assumption of medical titles more stringent. Even, however, with this change, it will be necessary for accusers to step forward and prosecute. Thus it appears that district associations, for the prosecution of offenders, cannot be dispensed with.

One of the great objects kept steadily in view, by the earnest partisans of medical reform, was uniformity of education and qualification throughout the profession. If that great object has not yet been effectually obtained by the exertions of the Medical Council, it cannot be denied that at least a signal improvement has been accomplished on the state of things, relative to this point, which existed before the passing of the Medical Act. In so far as respects regulations, the Council have pretty well succeeded in getting uniformity to a minimum standard of education and examination. Under any circumstances, absolute uniformity, after so many years of rivalry and contrariety of interests, could not be looked forward to except as the effect of several years of watchful superintendence.

It is to be remarked, that the only way in which the Council can compel a refractory licensing board to conform to its rules, is by a complaint to the Privy Council, and, if the Privy Council see fit, it may suspend the right of that licensing body to confer a qualification. This rule seems simple enough in words, but it is found to be both costly and tedious to carry the rule into effect. It is one of the parts of the Medical Act on which amendment is proposed in the alterations suggested by the Council.

It is, beyond all doubt, both the interest and the duty of the members of the medical profession at large to back the Council in the exercise of this part of their functions. It is only by the voice of the profession that any offending board, be it of great or small name, in the Empire, can be compelled to pay respect to the rules enjoined by the General Council; and there can be no

doubt that the voice of the profession will weigh far more effectually in putting down opposition, on such points as uniformity of regulation and examination, than appeals to the Privy Council.

At present, unquestionably the proceedings of the General Council are far too little known or attended to by the profession at large. The minutes, as published, are too little interesting to entice men busy with their daily routine of practice to spend time in their careful perusal. Some means should be taken without delay to create a larger interest throughout the profession with respect to these proceedings.

It is seen that a difference of opinion exists among the members of the Council as to the expediency of admitting reporters to give publicity to all their proceedings. Without debating that question, or giving any decision regarding it, there might surely be, in the meantime, a compromise by employing some one to give an intelligible digest of the proceedings, including at least a sketch of the more important debates. Let those among the members of the Council who oppose the admission of reporters consider this point, for they may depend on this, that unless something is done to give an interest to the proceedings of the Council, the cry for the admission of reporters will break through all opposition.

It might be well to try an interesting digest of the proceedings and arguments before having recourse to a verbatim report. In whichever way this debate is ended, the final result must be, that the voice of the profession will much more largely influence the votes of the members of the Council on important questions, so that no overbearing corporation or licensing board will be able to restrain the Council from carrying out whatever regulations tend to the general benefit of the medical profession and of the public at large—that is to say, objects which are strictly in the spirit of the Medical Act itself.

Dr. M. McGee moved and Dr. Arnold seconded “That the thanks of the Society be given to the President for his valuable address, and that it be printed at the expense of the Society for distribution among the members.”

Dr. McGee gave a notice of a motion for the first Saturday in December “That the Medical Students be not admitted to the meetings of the Society.”

James Patterson, President

General Hospital November 7th, 1863

Present, Drs. Patterson, Reade, Cuming, Moore, Gribbin, McCrea.

The minutes of the previous meeting were confirmed.

The President then read a communication in reference to a proposed testimonial to Dr. McKay.

Some conversation ensued among the members in reference to the reports of Annual Meeting and Dinner of the Society.

Dr. David Moore moved and Dr. McCrea seconded “That an advertisement be inserted in the Banner and Morning News repudiating the report which appeared in those journals.”

Dr. Reade moved and Dr. Cuming seconded the amendment “That Dr. Arnold’s attention be called to the unauthorised report in ‘The Banner’ and that he be requested to attend on next Saturday to inform the Society if the report in question had his sanction.” After some conversation, the amendment was carried.

The President read a circular from the National Lifeboat Association on the subject of the resuscitation of the apparently drowned. It was agreed that the question should be taken up on Saturday November 21st.

James Patterson, President

November 14th, 1863

Present, Drs. Patterson (Chairman), Ferguson, Moore, Pirrie, Stewart, T. Reade, Little (Lurgan), D. Moore, W. MacCormac, H. Burden, McWilliam, Gribbin, Bryce Smyth and Whitaker.

Dr. D. Moore stated that he had been requested by Dr. Arnold to express his great regret that the report in question should have appeared in the Banner. Dr. Arnold was not aware that any rule bearing on the subject had been adopted by the Society.

Dr. W. MacCormac brought forward an account of a case of laceration of the urethra caused by a fall from a height of four or five feet on the perineum, and described the injury which was received thereby; he entered fully into the case, and gave a detailed account of the treatment he pursued which was attended with most satisfactory results.

Paper:¹ MR. F., the subject of the present remarks, is an athletic young man, about twelve stone in weight. Some weeks ago he sustained a very severe injury of the perineum in the following remarkable way. He was attempting to open a window of a house from the outside, there being in front of the window an area. It was dark at the time, and unaware of the existence of the area, Mr. F. stepped right into it. Across the area, from the street to house, stretched an iron gas-pipe, about an inch and a half in diameter. On this Mr. F. fell, coming astride the pipe with all the force derived from a fall through about five feet, and so exactly that he remained balanced for about a minute, his feet not touching the ground, in indescribable agony, unable to speak or move. I subsequently examined the place where this accident occurred, and I saw the iron gas-pipe bent for about a couple of inches out of its course, while at its insertions the very masonry was loosened.

¹ [Dublin Medical Press, 1864, January 13, p30.]

What I have described took place about ten o'clock on Friday evening, the 11th of September. Mr. F. was able, strange to say, to walk home, a distance of half a mile. He then tried, with much straining, to pass water, but failed, only blood came away. The following morning about nine a.m. I was summoned to see him. No urine had been passed since the accident. Mr. F. had spent the night without sleep and in great pain. The bladder was distended, the dulness reaching nearly as far as the umbilicus. The scrotum was as large as a cocoa-nut, and very black. The perineum was swollen, the swelling being limited posteriorly by the superficial perineal fascia. The skin of the scrotum and perineum was scarcely abraded.

At first sight I feared considerable extravasation of urine might have taken place through an injured urethra, and that I would not be able to relieve the distended bladder. With but little trouble, however, I introduced No. 12 gum-elastic catheter, and drew off about two quarts of urine, leaving the instrument in. After an interval of two hours I drew off nearly a quart more and removed the catheter. I then ordered one grain of opium to be taken every four hours until the intense pain should abate, and hot stupes to the scrotum and perineum. In the evening hæmorrhage from the urethra set in, which was with difficulty restrained by the nitrate of iron internally, and local cold applications. I did not introduce the catheter this evening for two reasons—1st, because Mr. F. had drunk scarcely anything during the day; and, 2nd, because the bleeding from the canal might be again induced. On Sunday morning and evening I introduced the catheter. The blackness and swelling were on the increase, and in the afternoon a severe rigor took place. From these symptoms I judged that some extravasation of urine had probably taken place. That evening I sought the advice of my friend Dr. Browne, and we agreed on consultation to defer active measures till morning, in the hope that the symptoms would abate. On Monday 14th, the scrotum was so much swollen and so black that it seemed as if gangrene would take place in it if something were not speedily done. I, therefore, with the assistance of Dr. Browne, made an incision in the raphe from the most dependent part of the scrotum back to the central point of the perineum, three and a half inches long and two inches deep, but not quite into the urethra, knowing that urine, if extravasated, would speedily and easily make its way into the wound at the nearest point. The relief afforded by the incision was almost instantaneous. There was no urinous smell in the wound, and bloody serum alone drained away. On Monday morning and evening I found it necessary to draw off the urine, the patient being quite unable to make water, and each time I introduced the catheter with increasing difficulty. On Tuesday, therefore, I decided that it would be well to allow the catheter to remain in as long as the canal would tolerate its presence. I hoped that I might

perhaps in this way avert the formation of a urinary fistula, but I failed in the attempt. On Wednesday 16th, I noticed a small hole in the bottom of the wound, through which I was able with a probe to feel the catheter, but I did not remove it until Saturday morning. On Saturday evening Mr. F. passed water for the first time without the assistance of the catheter, but, as I had anticipated, almost entirely by the wound.

I need not trouble the Society with a daily report of the case after this date. The treatment was directed towards preventing the formation of a traumatic stricture and thus allowing the fistula to close. I passed a full-sized bougie every day, and it was noteworthy how much the calibre of the canal would contract at the site of injury in the space of twenty-four hours. This tendency, however, gradually diminished. At the same time the perineal incision was closing up, and the quantity of urine that flowed by the wound lessened until it came drop by drop. On the 13th of October, all the urine for the first time came by the natural channel. I continued to pass the bougie, as the canal still exhibited a great tendency to contract. Subsequently, Mr. F. left town, but through my instructions he was able to pass a bougie himself, which he did every second day. On the 5th November, I heard from my patient; he expresses himself as quite recovered. The parts have regained their natural appearance and size, the wound is quite healed, and the tendency to contraction in the urethra continues to diminish. This case I consider interesting for the following reasons:—First, the violence of the fall producing so little external injury, the force of impact of a body 12 stone in weight falling through five feet being equivalent to about 24 cwt. Second, the extreme relief afforded by the incision, deep and long, made through the swollen parts. Third, the anticipation of the formation of a stricture which is all but certain to follow a wounded urethra, thus allowing the fistula which had formed the opportunity of closing up speedily.

Dr. Thomas Reade was surprised that no infiltration of urine took place, as it rarely happened that in cases where so much violence had been applied that infiltration to a large extent did not take place. He also thought that incisions into the distended scrotum should have been sooner resorted to.

Dr. D. Moore wished to know whether the swelling arose from extravasated urine, blood, or serum.

Dr. Pirrie thought that the urethra was injured in the first instance and not ruptured, and that the swelling was due to the violence inflicted on the part and not to extravasated urine. He also wished to know whether ulceration of the canal might not have taken place and so caused the opening into the urethra.

Dr. T. Reade thought that there was no laceration of the urethra, that inability to pass urine was not caused by the injury to the urethra but by the shock and extravasation round the neck of the bladder.

Dr. D. Moore thought that the catheter should have been retained in the bladder as to often great difficulty occurs in its reintroduction. It might in this case have prevented the formation of the urinary fistula which afterwards occurred.

Dr. Ferguson thought that no sufficient cause had been brought forward except the original injury to account for the formation of the fistula in 3 or 4 days afterwards.

Dr. W. MacCormac did not make incisions earlier as there was not at first sufficient swelling, or any certain evidence of extravasation of urine. He made the incisions when he found that the scrotal swelling and blackness was increasing, and that a severe rigor had occurred. The incision was freely made but not into the urethra. There was no urinous smell, only bloody serum drained off.

He concluded from that if extravasation had taken place, it must have been only a drop or two and this view was confirmed by the formation subsequently of a fistulous communication with the wound in the urethra while the catheter was being retained.

He did not allow the catheter to remain in permanently in the first instance because not having found any difficulty in passing the instrument, he did not think that the urethra was injured to any extent or that there would be any difficulty in again introducing it should the patient be unable to pass water for himself.

James Patterson, President

Pathological Room November 21st

Present, the President, Drs. Arnold, Dill, Keown, T. Reade, D. Moore, Ferguson J. C., Stewart, Gribbin, W. MacCormac.

Dr. Arnold objected to that part of the minutes of the last meeting which referred to him.

Dr. M. McGee's letter was read by Dr. McCrea and referred to Council. Dr. McCrea gave the following notice of motion: [page here blank].

A letter from Dr. Arnold was read. Dr. Ferguson moved and Dr. T. Reade seconded that the letter be referred to the Council.

Dr. Dill then gave an account of a case of aneurism of the abdominal aorta and exhibited the diseased parts. Dr. Dill stated in reply to Dr. Ferguson that no absorption of the vertebræ could be detected.

Professor Ferguson said that the early symptoms were exactly those of aneurism. The œdema was to have been expected. The paralysis is a more frequent concomitant of a later stage of the disease when the vertebræ begin to be affected. What was the cause of death? The effusion was almost cadaveric. The lungs were emphysematous, which fact accounts for the clear percussion sound but renders improbable the occurrence of pleural effusions. Might the effusion

into the abdomen be the cause of death?

Dr. D. Moore thought this was a good illustration of the method by which a natural cure is affected. When the man was in the Dreadnought, the aneurism was evidently in a different state from that in which it was in the General Hospital. The filling up of the sac with concentric layers of clots accounts for the absence of symptoms in the later stage of the disease. The breaking up of the clot may have caused the failure of the circulation in the lower extremities.

Dr. T. Reade said that there was, on record, several cases in which effects analogous to those of ligature had been produced by the pressure of the sac on the artery. A preparation in Guy's Hospital illustrated this.

Professor Ferguson would have considered it strange if the aneurism, situated as it was under the pancreas, and covered with serous effusion had yielded any better marked signs.

Dr. D. Moore could not see how, when the causes that gave rise to bruit did not exist, there could be a bruit.

In reply to Dr. Saunders, Dr. Dill said that there was no difference between the femoral and radial pulsation. In reply to Professor Ferguson he said that all the distress present was dyspnoea.

Pathological Room November 29th, 1863

Present, the President, Professor Ferguson, Drs. T. Reade, W. MacCormac, Keown, H. Burden, McGee, Gribbin, D. Moore, Pirrie, Warwick, Cuming, Whitaker, McCrea, Stewart.

The minutes of the previous meeting were read and confirmed.

The report of the Council in reference to Drs. W. McGee and Arnold having been brought up; Dr. Cuming moved and Dr. Keown seconded that it be adopted. Professor Ferguson moved "That Dr. W. McGee's original letter be cancelled, and that the Secretaries be requested to acknowledge this letter of today and to express the satisfaction with which it was received by the Society; that the consideration of that part of the Council's report which refers to Dr. Arnold can be deferred till next Saturday." The amendment was carried.

Professor Ferguson gave an account of a case brought before the Society at a previous meeting in which operation of tracheotomy was performed over year and a half previous to death. He read the report furnished by Dr. Murney.

Professor Ferguson said that from the first this case was un-promising, and that tracheotomy was evidently [done] the time when it was

Dr. T. Reade said that the most striking thing in the case was the ease with which the operation was performed. Dr. Reade once performed this operation on a patient in articulo mortis who had previously

been to no purpose advised to have the operation performed. The patient lived for two years after the operation. A very deep incision was necessary to reach the air passages. The patient died with pneumothorax.

Dr. Cuming said the variations in depth at which the trachea was reached was considerable.

Dr. McGee had operated on a case in which the patient was almost departed.

Professor Ferguson enquired how in Dr. Reade's case the patient was able to speak immediately after the operation and not afterwards.

Dr. Reade said that the voice was present until the tube was inserted.

Dr. D. Moore said that the turgidity of the cervical veins and of the very vascular thyroid body would make a great difference in the depth of the trachea.

Thomas Reade V.P.

Pathological Room

December 6th

Present, Dr. T. Reade V.P. (in the chair), Professor Ferguson, Drs. Dill, McWilliam, MacCormac, D. Moore, Cuming, Stewart, McCrea.

Dr. MacCormac stated that no further communication had been received from Dr. Arnold, and that the Council presented again its former report.

Dr. Ferguson moved, and Dr. Cuming seconded, that the report be adopted. The report was adopted.

Dr. W. McGee deferred the consideration of his motion till some future occasion.

At the suggestion of Dr. McGee the Society recommended the Council to make a list of members.

Dr. W. MacCormac stated that the Council was already making arrangements for this purpose.

Professor Ferguson gave an account of a case of pleuritic effusion. Dr. Dill saw him early in Summer, when there was great dyspnoea, with pain over right lung, dullness on percussion in subclavicular region, no splashing sound, but raise in amphoric vocal resonance. He looked on it as tubercular pleurisy. Dr. Dill again saw him weeks subsequently when the dullness had greatly extended.

The patient was introduced, and examined by several members. The measurements of his chest taken on the present occasion were, on the right side $19\frac{1}{8}$ in., on the left, $17\frac{7}{8}$ in. The prominence of the right intercostal spaces had considerably diminished since Dr. Ferguson's last examination.

Professor Ferguson suggested a number of queries in reference to the case. The first was the origin and cause of the hæmoptysis.

Dr. Cuming thought tubercular deposit was the cause, and that the left lung was probably being affected in a similar manner.

Dr. Dill also thought that the cause was tubercular.

Dr. T. Reade in consequence of length of this

thought that ...

Second what gave rise to the gaseous and fluid effusions into the chest if it existed.

Dr. T. Reade had heard the splashing sound in his own person, on one occasion, when on horseback. He had at this time what was considered incurable disease in the chest, and had had an attack of hæmoptysis.

Professor Ferguson thought that there was no tubercular deposition and that disease was acute and sthenic, in fact acute pleuritis. That both air and fluid were formed from the pleural sac. He thought that there had never been a fistulous opening, as in that case, the effusion would consist of atmospheric air, which never has been known to be absorbed, as the air in the present case had been. He thought that the sudden occurrence of hæmoptysis was evidence of the acute nature of the disease. There is no morbid respiratory sound at present. May not any slight irregularity in the sounds heard be accounted for on the ground that the left lung is also subject to pressure.

He attributes the altered sounds of the heart to the displacement. He thought that the sounds heard on the right side were transmitted through the fluid from the left side.

Dr. Cuming said it is evident from the signs of improvement at present He still thought that this had been phthisis. He thought that it was improbable that there had been a fistulous opening. The compression of the lung against the vertebral column ...

Dr. T. Reade thought this case worthy of future observation. He did not think this case phthisical. He thought that serous membranes could give out air. He mentioned a case of the late Dr. Drummond in which air had been frequently removed from the peritoneal sac.

Dr. Dill mentioned another recorded case which he thought worth comparing with the present case.

James Patterson
President

Pathological Room

December 13, 1863

Present, the President, Professor Ferguson, Drs. Saunders, T. Reade, Keown, Stewart, MacCormac (W.), McCrea, Cuming.

Dr. Cuming read a paper on a case of progressive muscular atrophy.

Dr. Thomas Reade referred to a paper of his own anterior to the publications of Roberts and Nagel. His case was symmetrical. The corresponding muscles on the two sides of the body were affected. There was, he thought, no fatty degeneration in his case. He tried all the remedies recommended and found that the magneto-electric current was most efficacious. He has obtained a very favourable result. Dr. Burden suggested an explanation that the only source of degen-

eration lay in some affection of the spinal marrow and was intimately connected with nutrition. Robert's thought it was a disease of the muscles. Disease of the spinal marrow had been frequently detected by the microscope.

Professor Ferguson saw Dr. Reade's case. The difficulty is to account for the case on physiological principles. He did not think the disease peripheral, and accounted for our not finding an explanation in the central nervous system by the very imperfect state of our knowledge of the pathology of the central nervous system. The symmetrical nature of the disease in Dr. Reade's case was against the idea of peripheral disease. He thought the disease quite different from paralysis and functional in its nature—a lack of nutrition. Circumstances in this case favoured Wilson Phillips idea of the irritability of the nerves, and electric current.

Dr. W. MacCormac thought that remarkable certain cases recently described in Germany, in which *Trichinella spiralis* had been found in the muscles throughout the body.

Dr. Cuming thought that the fact of the cutting of one of the roots being attended with general weakness of the muscles was against the idea of any dissecting action. Here is a fatty degeneration. We don't refer fatty degeneration of the liver to the nervous system.

No *Trichinella spiralis* had been detected in any of the cases, although submitted to the examination of imminent microscopists. There was in their cases fatty degeneration.

Dr. Cuming in reply to Dr. Ferguson said that examinations were unanimous on the exhibition of fatty degeneration, and that there was always fatty degeneration in the wasting of a muscle.

Dr. Saunders asked if there had been an *arcus senilis*.

Dr. Thomas Reade saw a case of paraplegia in which the patient was in fuller face than any man in the Pathological Room.

James Patterson, President

Pathological Room
December 19th, 1863

Present, the President, Drs. Stewart, Dill, Cuming, Gribbin, D. Moore, McWilliam, Whitaker, McCrea, Keown.

Dr. Dill gave an account of two cases of placenta prævia in which immediate delivery had been affected with favourable results.

Dr. Gribbin suggested the propriety of administering stimulants in these cases.

Dr. McWilliam referred to the recently recommended practice of partial detachment of the placenta.

Dr. D. Moore thought that partial separation would be injurious.

Dr. Cuming said that the only question of interest in the first case was as to the propriety of administering ergot of rye.

Dr. Dill, in reply to some observations of Dr. D. Moore, stated that the difficulty of turning was much greater in the earlier months of pregnancy than in the later. He thought the loss of time was the great objection to the use of ergot. The sickening influence of the drug was also objectionable.

David Moore, Chairman

Pathological Room
January 2nd, 1864

Present, Drs. D. Moore (in the chair), Moore, Gribbin, McWilliam, McCrea, Dill.

It was resolved that the windows be painted as to partly prevent the rays of light from coming in.

It was also resolved that a cast of the diseased parts in Dr. Moore's case should be prepared.

Dr. Moore gave an account of a case of *Fungus Hæmatodes*.

Dr. Dill referred to the greater prevalence of this form of malignant disease in young people. He had seen the disease mistaken for abscess.

It was moved, seconded and carried that Dr. D. Moore be requested to open the discussion on the resuscitation question.

James Patterson, President

Pathological Room
January 9th, 1864

Present, the President, Professor Ferguson, Drs. Browne, Whitaker, McWilliam, Stewart, Keown, McCrea, Dill, MacCormac.

Dr. Browne gave an account of a case of fracture of the skull, and exhibited pieces of bone which had been removed. He mentioned a case in which great relief had been produced by trephining in a case of suppuration.

The president referred to the greater frequency of trephining thirty years ago, and the success which had often attended the operation.

Dr. Dill said that the place in which the fracture had occurred was the most invulnerable part of the skull. He had seen a case in which the central part of the right parietal had been driven in by a spade. There were no marked symptoms. The patient recovered, and lived for at least twenty years, with the fissure persistent. At various times during the healing of the wound, portions of the brain had oozed out. The fissure was an inch and a half deep.

Dr. Browne then described a case of strangulated hernia. "There was a tumour of the size of a walnut in the right groin. There was vomiting, but no symptoms of peritoneal inflammation. The taxis had been tried in vain. On division of the margin of the external ring, the hernia could be reduced, but the stricture still

remained.

By delicate manipulation Dr. Browne succeeded in dividing the stricture which had affected only a portion of the intestinal cylinder. The stricture was in the neck of the sac." In another case of Dr. Browne's the taxis, aided by chloroformization had succeeded, although the strangulation had lasted for eight days. He advocated early operation.

Dr. Keown referred to the practise turning the patient upside down.

In reply to Professor Ferguson Dr. Browne said there would be no case in which a surgeon could refuse operation.

James Patterson, President

January 16th, 1864

Present, Drs. Patterson (in the chair), Cuming, Gribbin, William MacCormac, Stewart, Whitaker, Dill, and Moore.

Dr. W. MacCormac stated that he thought Dr. Sylvester's plan of restoring the apparently dead simpler than that of Dr. Marshal Hall and equally effective.

Dr. Cuming thought that when vitality is very low, the patient should not be raised up suddenly. He believed that the drawing of the arms and elevating the shoulders would be attended with beneficial effect.

Dr. Moore agreed with Dr. Cuming in thinking that Dr. M. Hall believed that when the patient was put on his side, the chest expanded.

Dr. Dill related a case which had recently occurred in the General Hospital and in which the patient recovered from the effects of submersion. He believed that if the heart's action had ceased all efforts at resuscitation were useless. He did not believe in Marshall Hall's treatment at all, more especially in the treatment of stillborn children in which he had had great experience, and thought that artificial respiration, heat in the form of hot baths, with an occasional sprinkling of cold water, was by far the better mode of action. He also believed that the tying of the umbilical cord was often particularly useful.

Surgeon Gribbin thought that the allowing a few drops of blood to come away from the funis on tying it was a powerful adjunct to the warm bath and friction.

Dr. Dill while not differing from Surgeon Gribbin as to the advisability in some cases of allowing a few drops of blood to escape, thought that where vitality was low such a proceeding would be attended with much risk.

Surgeon Gribbin explained that he only adopted such a course in the case of children of a full habit of body.

Dr. Cuming thought the circulation through the placental circulation ought to be kept up as long as

possible in anæmia cases and that it was not in his opinion wise to divide the cord while the pulsation was low and the breathing feeble.

Dr. Moore thought that in those cases the cord should not be divided while the placental circulation continued.

Dr. Dill thought that the tying of the cord often caused increased vitality in very weak children.

Dr. Moore postponed the further consideration of his case of fungus hæmatodes.

Reade, V.P

Saturday January 23rd, 1864

Present, Drs. Reade (in the chair), Thompson, Keown, Stewart, Gribbin, McWilliam, Whitaker, MacCormac (W.), McCrea, Cuming, Moore.

Dr. Whitaker brought up a report from the Council in reference to the microscope which Dr. McGee had lent to the Society, and which he now asked to be returned. It was resolved that, in as much as Dr. McGee's microscope although more than a year in the keeping of the Society, had been very little called for, it is inadvisable for the Society, at present, to purchase a microscope. It was also resolved that the thanks of the Society should be given to Dr. McGee for his kindness in lending his microscope.

Dr. Keown read a paper on the influence of a ship's malaria in the production of pulmonary diseases.

Paper:¹ *Gentlemen,—The influence of miasmata or malaria in the production of the severest forms of fever on board ship are well known to the profession, and the medical history of our navy has from time to time presented us with not a few melancholy instances in which the ships' companies have been prostrated by fearful attacks of yellow fever, cholera, and dysentery.*

The morbid agency of ship malaria in the production of diseases of the lungs is far less common—not that sailors are exempt more than others from lung disease—but disease of this kind becoming endemic among a large ship's company is known to me only in two instances, both of which happened at the same time, and both of them in the Mediterranean station in 1860–61. It is not my intention to enter on the interesting and but little understood subject of malaria; but supposing it to be composed of gases, which, being absorbed by the lungs, give rise to diseases, such as typhus and the several forms of infectious fever, as also the exanthemata; the wonder is that the lungs should not always be the parts first affected; yet experience points to the blood as first suffering the toxical effects of miasmata, and subsequently the different organs of the body.

An attempt has been made to divide malaria into organic and inorganic; the first giving rise to infectious diseases; the last being confined to the bodies affected. No doubt there is some truth in this, but we so often

¹ [Dublin Medical Press, 1864, April 6, p355.]

find the two together that it is seldom possible to separate them, and so far as the following remarks go, I shall not venture to present them in their distinct forms.

A great element of strength has been added to our naval power by the introduction of steam into large ships; but at the same it has introduced an element of weakness by adding considerably to our sick lists. In warm climates this is particularly felt, more especially in the line of battle ships. If these are frequently under steam and supply themselves with fresh water by the distillation of sea water, we can easily fancy the effects of such great heat with moisture acting on the wood-work of the ship, and the carbon and sulphur of the coal, and if, in addition to this, the ship is found to have black pitchy-like matter in her hold, we need not look further for the elements to produce disease. Most of you know that the ship's company and officers sleep on the lower fighting deck, and on the orlop deck below that one.

Now, at sea it is necessary to close the ports, and you can fancy from 700 to 1000 persons so situated would soon rob the air of its oxygen, and we can easily imagine, in the case of a ship like the *Cressy* that I am about to lay before you, that certain combinations of hydrogen and carbon, and hydrogen and sulphur, would tend to vitiate the air and consequently poison the blood, independent of the marsh malaria that subsequently appeared on board in the specific form of remittent and intermittent fevers.

My object at present is to relate to you as briefly as I can the effects in one particular ship of ship-malaria on the textures of the lungs, and incidentally to notice other grave forms of disease that arose at the same time from the same malaria and the miasmata external to the ship. H.M.S. *Cressy* of 80 guns, originally built for a sailing-ship, had roomy gun-decks, but her cockpit and holds were crowded and badly ventilated, and her stoke-hole, when long under steam in hot weather, rose to 140° F., prostrating the stokers and engineers. My first impression of her was that she should never have been sent abroad.

However, in April, 1859, at Sheerness, she was hastily manned. Our crew had been gathered from all quarters, and many of them carelessly examined at the outposts from which they were sent. Out of an average crew of 760, 511 were under 25 years of age, and for the most part inexperienced in sea life, and deficient in the physical growth and endurance required for good men-of-war sailors, still I must also say that many ships were not better off than ourselves in this respect. Some misunderstanding with our good friends the French determined the Government to increase the Mediterranean Fleet, so we left England in June, 1859, and arrived off Naples in September, visited Palermo, and returned to Naples in December. The winter of that year was unusually stormy and wet, and the state of the air markedly malarious to us and all visitors to Naples.

Ten miles from Naples is *Baiae*; we went there in January. The neighbourhood of this place is noted in ancient as well as at the present time for its malaria. The safest time to visit such places is in winter. Now, I am thus particular in noticing hurriedly these matters to show you that we had an external malaria for a time to contend with; and let me say, while looking back at that land of antiquity and celebrated fables, with its hot-baths, of Nero, the Elysian fields, Lake Fusaro, and Avernus, that I have wandered over its dreary and deserted fields, and I believe the air was more agreeable to me than that of Belfast. So much for the nasal influence of malaria.

Thus, before the period when my story commences, the ship's company had suffered from malaria at Sheerness and off Naples at the end of the first year. The following, taken from the nosological returns, are a few of the most important diseases connected with this subject, which, I think, will best indicate our sanitary state previous to the appearance of the pulmonary endemic among us:—

Typhoid fever, 1; continued, 3; remittent, 3; intermittent, 26; bronchitis, 6; pleuritis, 4; pneumonia, 1; phthisis, 2; catarrh, 234; cynanche, 27; dysentery influenza, 34; diarrhoea, 171; erysipelas capitis, 3; modified variola, 2; epilepsy, 8. At the end of this year the daily sick list amounted to about ten per cent. of all hands.

The history of this pulmonary disease has reference only to the commencement of the second year of our commission, and that was in April, 1860, extending to May, 1861, when the ship was paid off. During this period of little more than thirteen months, 180 cases of pulmonary disease appeared, the number so unusual and the disease so peculiar in its features, will, I trust, be sufficient excuse for giving it an importance worthy of your consideration.

When lying in the sheltered harbour of Malta, the crew seemed unusually susceptible of atmospheric changes. At that time I was disposed to attribute this to their previous exposure to the malaria while off Naples, and subsequently to trace the pulmonary disease to the catarrhs that had prevailed on board the ship; but subsequent experience left no doubt in my mind that all along the ship herself was the chief source of the sickness. The malaria, I think, tended also to induce a large number of the bowel complaints which prevailed at all seasons. Great care had been taken to have the ship's decks, engine-room, and bilges, kept clean; yet it was only in August of this year that, while clearing out the forehold, a great quantity of black mud was found beneath the water-tanks. Something similar was found also in the *St. Jean D'Acre*, the other ship similarly affected. Here, then, as far as could be seen, was the *fons et origo malorum*.

The crew were favourably situated for the preservation of their health—lightly worked, well and carefully

clad—nearly all the time on fresh provisions—the food sufficiently abundant, but rather deficient in variety; still it was the same as in other ships. The unavoidable crowded condition of the lower decks at night was the same as in all large ships; the men were placed in hammocks near the deck above them, and the heat and closeness of the air were often oppressive.

The Admiralty have lately reduced the number of guns and men in all ships, so as to give greater space for ventilation, and in the course of time we may expect further improvements in the sanitary regulations of our ships.

In April there were 24 cases of catarrh and cynanche; in May fewer; but now the lung disease became prominent, and at the end of June quarter stand thus—Bronchitis, 4; pleuritis, 1; pneumonia, 3; phthisis incipiens, 5; equal to the whole number that are noted in the first year.

We remained at Malta until the middle of June, either in harbour or with occasional cruises off that island. During July we were cruising about the Ionian Islands and coast of Greece. There appeared to be an improvement in the general health of the crew so far as the total number added to the sick list was concerned, but not in the class of pulmonary diseases; ten were added to the list, bearing for the most part a bronchitic character. We were at Malta during August, and 18 more were added. On the 30th we sailed for Naples, and during September only 7 fresh cases appeared; altogether 36 cases in this quarter, of whom 15 were sent to hospital, and 4 invalided. During the fourth quarter, and third of the disease, we were either anchored or cruising off Naples, or at Palermo for a few days, and also at Messina for fourteen days. In this sheltered port the disease seemed to pass more rapidly out of its subacute stage. In October 10 were added; November, 16; December, 7; one of these was a case of relapse.

I have stated that the prevalence of catarrhal affections in the first quarter of this year seemed to have implanted the seeds of this lung disease, because I remarked at the time that they became markedly adynamic, especially where the throat was affected. In May, three patients, who were in the first instance affected with catarrh, then showed pulmonary disease, and a considerable number subsequently, in the winter season, when the cold N.E. wind prevailed, while off Naples, were in the first instance preceded by catarrh. Perhaps if the ship had been sufficiently quiet at all times to examine patients, there might have been detected earlier the very first symptoms of local congestion; as it was, the usual times, with frequent exceptions, however, for using the stethoscope were half-past nine p.m. and during Divine Service on Sundays.

The following table shows the number of catarrhs and tonsillitis during each quarter as compared with the total amount of pulmonary disease during the same periods. They are all fresh cases:—

		Catarrhal	Pulmonary
1860—	First quarter	112	—
„	Second do	36	13
„	Third do	18	36
„	Fourth do	50	33

So far as this goes no necessary dependence seems to exist, the one on the other,—yet it was more than probable that catarrh aided the action of the malaria, and tended to the development of the disease in certain cases, and indeed anything which reduced the physical powers seemed to invite the attacks of this insidious malady.

We commenced 1861 without a prospect of improvement; our ship's company were evidently physically deteriorating; 12 fresh cases appeared in January, and the sick list amounted to nearly ten per cent. of the crew. We were still off Naples. In February, although the weather was fine, catarrhal affections of the tonsils and catarrh with slight fever were common; 21 fresh cases were added to the list, the sick list increasing to 13 per cent. of the crew. During March pulmonary disease was more prevalent than in any previous month; 49 cases were added. It will be seen by the following table that the total number in this quarter equals the whole of the previous nine months, and also shows the progressive increment of the disease:—

First quarter of 1861—Pneumonia, 62; pleuritis, 13; bronchitis, 2; phthisis incipiens, 5; invalided, 5; sent to hospital, 35; discharged to duty, 19.

We left Naples on the 1st March, and arrived at Malta March 5th, with a sick list of 137; of these the most important were—febris remittens, 2; febris intermittens, 3; chest disease, 22; catarrh, 23; tonsillitis, 6; venereal, 28; diarrhœa, 16; phlegmonæ, 15; and variola, 1. It is not surprising that with a list of more than 20 per cent., that pulmonary disease should be then more prevalent, and so it remained during March in the sheltered harbour of Malta. On the 6th of April we left Malta for Gibraltar (the ship was ordered home) with a sick list of 100; of these 30 were chest disease; in this month only 9 fresh cases were added, two of the most acute cases were in boys aged 16. We arrived at Gibraltar on the 16th; after this only 2 new cases occurred.

During the passage to, and while at Gibraltar, there was a great improvement in all our cases, including the invalids, for passage home on board.

We left Gibraltar for England on 25th, and arrived at Plymouth May 8th. A marked daily improvement appeared in nearly all the cases of chest disease. The prospect of getting home no doubt had a good effect. When at Plymouth our daily sick list was reduced to 48, 9 of that number being lung diseases. The subsidence of the disease as we approached the Atlantic, and its final departure in the Atlantic, are very remarkable. This

table shows the beneficial effects of the Atlantic air:—

Added at sea after leaving Malta—14 pleuro-pneumonia.

Added while at Gibraltar—2

Added after leaving till arrival at Plymouth—none.

I have always been impressed with the healthful influence of the Atlantic air as compared with that of the Mediterranean; whether that depends on its having a larger portion of ozone I am unable to say, but the fact is so.

The cases of relapse did not exceed ten per cent., and were chiefly pleuritic.

I am unable to state the fate of those left at Malta, and of those invalidated from time to time, but the mortality, as far as I know, has been small, only one case died on board, and two in the hospital, while we were on the station. I think that the various forms of the disease might be classed under the head of endemic pleuro-pneumonia. But I feel that any terms I have used for the subacute and chronic forms of the disease imperfectly describe it; in these cases the pulmonary tissue took on a silent congestive action with every probability of its terminating in tuberculization. That appeared to be the most probable, and in many cases, I believe, the actual climax of the uncured disease.

I have learned since leaving the Mediterranean that the patients sent to hospital with this pulmonary disease from the St. Jean D'Acre and Cressy apparently communicated the disease to other patients in the wards who had been admitted for other affections. If this is proved, it will form a very remarkable feature in connexion with this malady.

The symptoms—The commencement of the pulmonary disease, so long as it was confined to the lungs alone, was very insidious. In many cases of convalescents from other diseases, when no progress was made to health, and yet no complaint made of the chest, I considered it advisable to examine the chest, and have found passive congestion existing with shallow breathing and dulness on percussion. Sometimes it has commenced with catarrhal symptoms, or flying pains about the chest, or diarrhoea, or persistent cephalalgia, and a sense of malaise, loss of appetite, or an actual feeling of exhaustion; the pulse small and frequent, followed by slight febrile reaction after the patient was placed in bed. It was seldom confined to one lung alone; the lower lobes have been nearly in all cases the parts first affected, and the left most markedly so. But even in the same cases not unfrequently sub-crepitating râles were heard in the apices of both lungs. During the progress of the disease pain has been generally referred to the part affected, but more frequently the patient complained of a sense of constriction or weight across the chest; the pain when acute was generally in the lower borders of the lungs, and where persistent local pleuritis was detected. The lower anterior and lateral parts of the left lung have been most remarkably affected. In

the chronic cases, requiring constant counter-irritants to divert the pleuritic affection, inability to lie on this side has at the same time been complained of.

The respiration, frequently shallow and bronchial at first, was accompanied with puerile breathing in the upper lobes, and in the middle sometimes sibilant râles. Increased resonance of the voice, with bronchophony, dulness on percussion, and the heart's action extensively diffused, with loss of expansion in the parts affected, were the second earliest indications of the disease. It almost seemed as if the congestion followed partial paralysis of the lung textures. Certainly all through the course of the disease, and in the daily investigation of it, the loss of capacity, evidenced by the attempts to take a full inspiration, were the most prominent ocular proofs of diseased action going on. The cough has been generally slight, short, and occasional, and seemed to cause no uneasiness, unless there were accompanying bronchitis or tonsillitis; most frequently the cough seemed to depend on subacute inflammation about the larynx. The expectoration was, with few exceptions, scanty and mucoid, and furnished no decided evidence of pneumonia. The exceptions were where bronchitis became prominent, and then it appeared thick, glairy, and even purulent. The rusty expectoration of pneumonia only appeared in one case terminating in the suppurative stage; this was a fatal case.

A dusky hue of the face I have often noticed on their first application; in a few cases it was very remarkable; the pulse, except where there was pyrexia at the outset, was frequent, soon becoming weak, but still frequent; headache was a common attendant, with restlessness at night, but rarely were night-sweats complained of. The pyrexia in a few cases, especially those with pleuropneumonia, was accompanied with the hot pungent skin and headache so well known. But these were not so persistent as might have been expected, considering the amount of local inflammation. They generally subsided by the third day, or even sooner, leaving probably a night exacerbation to follow. As the disease progressed it was attended with wasting of the body as a general rule, and the patients complained much of debility and occasional dyspnoea. The stage of consolidation, either in large portions or partial, whatever its real nature might be, existed in all the cases invalidated, and in those treated on board was slow in disappearing. In the few cases of acute pneumonia the tissues were early and rapidly restored to their normal state, or a permeable one, attended with weakened expansive powers. In such cases the system appeared to possess energy enough to rapidly eliminate the poison, and early restoration to health followed. The chronic stage on board was attended by detached localized inflammation of some part or portion of one or both lungs, and in the few cases of relapse it has been confined to one lung alone, or portion of one. 23 are noted in which pleuritis

at first was the most prominent part of the disease, the majority of these subsequently showed some pulmonary congestion. One feature in these was remarkable, the left pleura fifteen times out of twenty was the part chiefly affected. Why it should be is not very apparent. Perhaps the heart's motion and its proximity might aid this; pleuritic affections were liable to return again. It seemed in some cases as if the pleuritic inflammation saved the lungs. Effusion into the pleura was not detected in more than four cases, but it is more than probable that in many of the cases pleuritic adhesions took place.

Intercurrent attacks of diarrhœa and dysenteric diarrhœa were common both in the earlier and later stages of the disease. Nothing was more common than patients, especially in the first quarter of this year, to complain only of diarrhœa, and in three or four days' time attention was directed to the chest.

There are few things in a ship give greater proof of the want of good health in the crew than the prevalence during the year of bowel complaints. A comparison of this year with the previous one shows 316 as against 189 of the previous year; and they were generally slower in yielding to treatment than before. The treatment, taken as a whole, was directed to the support of the patient, especially after experience showed the local origin of the malady, chiefly arising, I think, from a ship malaria. The consequent supervention of pneumonic congestion, depending upon the presence of a morbid poison in the blood, and affecting, first of all, subjects predisposed by constitutional debility, and in some few by the poison germs of other diseases deteriorating the quality of the blood; all these causes tending to make the disease more intractable, especially in the locality of its origin. In a few cases, not exceeding I believe five, where there were pleuro-pneumonia, high fever, oppressed breathing, and a full pulse, I have not hesitated to bleed once from the arm, and with the best effects, and by following this up with antimony and small doses of calomel, until the system showed its effects, the disease has been cut short (let me just say that the fatal case on board was not bled). In cases presenting less urgent symptoms leeches have been applied to the part most affected, and where leeches are plentiful, I think they are preferable to the use of the lancet in nearly all cases. The majority of the acute and subacute cases have been treated at first with a mild course of mercury combined with ipecacuan until the gums showed its effects, or while stethoscopic signs of inflammation existed. As the character of the disease became more fully understood, the pil. hydrar. was given with the quinx sulph.

From the first, and during the progress of the disease in its various stages, much relief was obtained from the use of turpentine epithems, sinapisms, and blisters, besides occasional opiates and aperients. These formed the leading points of the treatment in the acute

sthenic cases. A few days under treatment always showed a tendency to fall into asthenia. Wine and nourishing diet were early given, being, in my estimation, the best part of the treatment. But few of the cases were long confined to bed, not alone for want of room, but where the patients were well enough to move about I thought it better for them, as I observed that the confinement to the recumbent position induced congestions on the posterior surfaces of the lungs.

The stage of asthenia was the most difficult to deal with. How these vital organs were to be brought to a state of health with the means at hand on board ship gave serious cause for consideration. The state of the blood, its defects and wants, we are left to conjecture on; but it was evident from the weak pulse and partially consolidated state of the lungs, that an agent was required of no ordinary kind, and being at a loss for that, I have given the potassæ iodidi, gr. ii. cum decoct, cinchonæ, or the quina sulph. gr. ii., ter in die. Instead of this, the following has been tried:—Tinct. ferri muriat. m.xx.; potassæ chloratis, gr. v., with vegetable tonic infusion ter in die with no particular success.

During the latter part of January, also in February, as our quinine ran short and the tinct. ferri mur. is easily made on board, I have been in the habit of giving it in doses of m xv., with hydrargyri bichloridi, gr. 1-12th, and a little syrup bis ter in die. This seemed to answer as well as anything else, and I believe that the tonic and alterative doses of the bichloride to be tolerably efficient in producing a new action in the lungs, and probably with the iron tend to change the unhealthy state of the blood. A moderate quantity of the potassæ iodidi may be useful; but after a time I think it tends to thin the blood and weaken the stomach. The cod-liver oil with quinine was given. It was apt to disagree with the bowels, but after a time it was taken with good effect in supporting the patient, if it did not act as a remedial agent. Dry-cupping was very frequently used in the chronic cases, but I found it far inferior to sinapisms in giving relief. I am by no means satisfied that the plan of treatment above detailed is the best. If I had these patients on shore with more ample means at command, plenty of good milk and vegetable food to give them, and means used to keep up a free action of the skin, but little medicine would have been required. I have had doubts all along as to the propriety of giving mercury except in very acute cases; but whatever plan of treatment may be adopted, one must feel that in the locality of the disease we have to contend with the malaria and its depressing effects on our patients; so that, as a general rule, the removal of the patients from the ship or station appeared to me the best thing that could be done for them.

I will not further trespass on your time by entering on the preventive measures used, this would bring us to the domain of naval hygiene; a subject I think of great importance to all who take an interest in the mainten-

ance of that naval supremacy we desire always to possess. It would naturally be expected that a larger than usual amount of other diseases would appear during the period I have spoken of—(viz., thirteen months), and they will be found to greatly exceed that which happened in other ships on the station.

The nosological synopsis shows that out of a total of nearly 2000 cases of all kinds placed on the sick list, that besides the 180 pulmonary cases there were 13 of continued fever; 2 remittent; intermittent, 23; variola, 3; epilepsy, 3; insanity, 2; delirium tremens, 4; cephalalgia, 25; catarrh, 213; cynanche, 54; laryngitis, 1; morbus cordis, 3; dysentery, 15; diarrhœa, 301; syphilis, 139; gonorrhœa, 13; orchitis, 26; rheumatism, 108; ophthalmia, 15; phlegmonæ and abscess, 303; ulcers, 95; simple debility, 19; scurvy, 2.

The St. Jean D'Acre was the other ship similarly affected, she carried 100 guns, was much superior in every way to the Cressy, roomy and well-ventilated. The disease appeared in her before she left the coast of Ireland, and she was kept much longer in commission than the Cressy. On inquiry I found that with the exception of 12 cases of hæmoptysis, the disease was nearly identical in its features with that in the Cressy. The surgeon writes to me: "It was astonishing how rapidly they got well on approaching the Channel; men with habitual weak pulse, emaciated and short-winded, got well rapidly as the temperature became reduced."

In the Lancet for this month I find that this subject has been brought before the Epidemiological Society of London by Dr. Bryson, the present Medical Director-General of the Navy, and he gives the following comparative table of two large ships not affected by this endemic, they are placed first on the list. It has reference only to the year 1860, and includes half of the period I have referred to:—

Ships	No. Crew	Sick cases in year	Lung	Bowel	Fevers	Ulcers
Marlborough	1145	937	129	64	10	75
Agamemnon	840	881	241	58	17	30
St. Jean D'Acre	815	1601	401	171	136	115
Cressy	720	1483	298	254	12	102

"The deaths from disease, were in the St. Jean D'Acre and Cressy twice as numerous as in the Marlborough notwithstanding the smaller crews of the former."

Dr. Thompson said that in his time in the Navy, lung disease was very prevalent.

Dr. Reade did not see why the malaria should not influence the ordinary affections of different organs to which different men are subject from changes of climate. The observations of Dr. Keown made the propriety of sending cases of chest affections to the Mediterranean doubtful.

Dr. Cuming remarked on the absence of intermitting from Dr. Keown's report. He pointed out an analogy between Dr. Keown's cases and typhoid pneumonia arising from overcrowding.

Dr. Keown then exhibited the Resuscitation Apparatus in use before Drs. Marshall Hall and Sylvester's methods were introduced. He recommended Sylvester's method because heat could be readily employed which he considered the most important means.

James Patterson, President

30th January, 1864

Present, Drs. Patterson (Chair), Dill, Keown, Scott (Aughnacloy), D. Moore, Whitaker, and Thompson.

Dr. D. Moore introduced a patient presenting a very interesting example of Bronchocele, and having some remarks on the subject, wished to know what treatment the members present would advise him to adopt.

Dr. Keown suggested that strips of plaster round each lobe would be very useful. Iodine painted externally might be of advantage as also food dietary. He thought that Iod. Potass. when pushed too far did harm by impoverishing the blood.

The President, Dr. Patterson, related a case in which Bronchocele had occurred after great loss of blood from miscarriage, pulse always kept at 150, the patient seemed to suffer from lung disease, but eventually recovered and the Bronchocele disappeared.

Dr. Scott thought that no good could be derived from treatment. He thought that it might be well to introduce an exploring needle to determine the contents of the tumour. He referred to a case in which a young woman came to him suffering from Bronchocele. He passed a lancet into the tumour and a quantity of serous fluid at once flowed out. The Bronchocele was considerably lessened but no permanent advantage ensued. He thought that no external rubbing or application could be of use.

Dr. Dill suggested that the presence of fluid might be detected by the transparency of the tumour, but having examined it, he could not determine its presence.

Dr. D. Moore thought that pressure could not readily be applied without interfering with the circulation through the large vessels of the neck. He also thought that it could be rather dangerous to open the tumour as a large vein or artery might readily be wounded and thereby give rise to troublesome hæmorrhage.

Dr. Keown would not expect to find any large vessel at all superficial in that neighbourhood, the veins which ramified externally could readily be avoided.

James Patterson, President

**Pathological Room
February 6th, 1864**

Present, the President, Professor Ferguson, Drs. J. Reade, Stewart, Keown, W. MacCormac, Whitaker, Saunders, McCrea, Messrs. Gribbin and Grattan, Drs. Browne, D. Moore.

The President proposed Mr. Croskery as a member of the Society.

Dr. Whitaker then read a paper on the British Pharmacopœia and the changes introduced therein.

Paper:¹ *The British Pharmacopœia having been at length published after a lengthened interval, during which its appearance was anxiously looked for by the profession, and especially by those engaged in the practice of pharmacy, and its use having been enjoined by the Medical Council, it appeared to me that there were many and cogent reasons why a review of its leading formulæ, more especially with regard to the changes therein introduced, and a statement of the new remedies which had been thought worthy of a place in our National Pharmacopœia might not be unacceptable to the members of this Society, many of whom from the exigencies of an extensive practice and the want of time thereby entailed, and others from want of inclination, might not care to wade through the dry details of the different medicines therein ordered, but content themselves with prescribing the ordinary simple remedies which they had heretofore proved and found useful.*

In the remarks which I am about to make, I have endeavoured to bring prominently before your notice those medicines which are in general use, to point out the changes in the formulæ for preparing them, and to call attention, more particularly, to any alterations which may have been made in their strength, as I am aware that with you, Gentlemen, the most important consideration is the safety and welfare of your patients, and it matters little to you in what manner the different medicinal compounds are prepared, so long as they are what they should be, what they profess to be, and answer the purpose for which they are intended; while I have bestowed merely superficial notice upon those pharmacopœial preparations, which, though interesting enough to those engaged in practical pharmacy, present few points of interest to, and are rarely ordered by, the practitioner in medicine or surgery.

In the first place, to begin with the preface of the Pharmacopœia, the Medical Council in it refer to the difficulties inseparable from the compilation of one British Pharmacopœia for the first time—a Pharmacopœia which would satisfy and meet the wants of the medical profession of the three kingdoms. In the preparation of such a work, the representatives of London, Dublin, and Edinburgh, would each be ready to do battle for their respective compounds; and when we reflect that years ago an attempt was made by the three Colleges of Physicians to effect a union of the respective

Pharmacopœias of these countries, and that after a lengthened correspondence it was found impossible to reconcile the differences existing between these bodies, or to bring their views on the subject of the medicinal preparations which should be introduced into the Pharmacopœia into any approach to unanimity, it is not at all surprising that even with the authority of the Medical Council to enforce conformity, it was difficult to reconcile the different opinions held by the representatives of those bodies on the Pharmacopœia Committee.

I have no doubt that in a wordy conflict of this kind the Irishmen on the Committee were not the least backward in expressing their opinions freely, and if we may judge by the Pharmacopœia itself, not the least successful in urging the claims of the preparations of the Dublin Pharmacopœia, and showing to their colleagues the intrinsic merit which many of them unquestionably possessed.

One of the first points which strikes the reader of the Pharmacopœia, more especially if an Englishman,¹ is the fact that it is entirely written in English; where a Latin name is introduced, as in the case of all the simples and compounds mentioned in the Materia Medica, by way of apology an English name is also affixed; I suppose, lest the person studying the book might find much trouble in mastering the two or three words of Latin therein introduced. The Pharmacopœia Committee had no choice, however, in this matter, as a resolution had been passed by the Medical Council previously to their appointment, “that it be an instruction to the Pharmacopœia Committee that the Pharmacopœia be published in the English language, with the list of Materia Medica and compounds in the Latin language.”

I, for my part, think that while the directions as to the preparing of medicines might be given in English, still that it would have been much better to have ordered the different substances of which they are composed in Latin. So long as prescriptions are written in Latin, and I see many and valid reasons why they should be so, it would be well to accustom, as much as possible, compounders to the use of the language which they would meet in prescriptions, and if they could not read the Latin in the printed formulæ, what chance would they have of reading it in the handwriting of even the best writer among us, not to speak of the miserable scrawls which unfortunately too often they have to decipher. My idea is, that the compounders of medicine should be forced to a higher standard of education, and that the language of the Pharmacopœia should not be lowered to meet their ignorance.

*Next, as regards the weights, the drachm and scruple having been now abolished, I would wish the opinion of the Society as to the respective value to be apportioned to them. I presume that in Ireland the *z*i. means, and still will mean, 54.68, and the *ʒ*i. 18.22 grs.,*

¹ [Dublin Medical Press, 1864, v51, p189, 246, 323.]

¹ The London Pharmacopœia was always published in Latin.

while in England they will mean respectively 60 and 20 grs., when ordered, as I have no doubt they will be, more especially by the older practitioners, for many years to come.

The Medical Council say: "The Council in resolving to adopt for pharmacy the imperial ounce and pound could not assimilate the subdivision of the ounce to that of the fluid ounce without substituting a new medical grain for the troy grain, hitherto the medical as well as the standard grain of the kingdom. This alteration they did not consider advisable. It has therefore appeared to them a necessary consequence that the drachm and the scruple, the old denominations of weight between the ounce and the grain of pharmacy, must be abandoned, since they can no longer exist as both simple multiples of the latter and integral parts of the former. Accordingly, all who prescribe and dispense medicines are recommended to discontinue henceforth the use of the drachm and scruple weights." To have carried out their doctrine fully—viz., that no weight should be introduced which was not both a simple multiple of the grain and an integral part of a higher weight, it is quite evident they should have abolished the ounce of 437.5 grams. To weigh a large quantity expressed in grains will now require some trouble and calculation, the more so especially as in the Pharmacopœia the compilers seem to ignore the ounce, except where it is ordered by itself or its multiples, or its divisors by two or four, and order even for large quantities by grains. 1440 grains bring ordered in one formula, the calculation necessary to reduce this sum to ounces of the ordinary avoirdupois weight would, in my mind, give more trouble than could occur, in any circumstance, from keeping to the old troy weight.

Another objection arises from the fact that in the great majority of the preparations the components are ordered by the ounce, and hence much trouble occurs when we wish to know the number of grains in a given quantity; thus, Tincture Opii is ordered to be prepared by Opium one ounce and a half in a pint of proof spirit. Now, to find the number of grains of opium in the ounce requires some trouble and calculation: with the troy weight it would have been at once evident.

Had any change been necessary from the old troy weight, in use in England and Scotland, I think that the Council should have adopted the decimal system. I believe they did not wish to do so, lest Parliament should at some future time introduce a system of that kind into use throughout the kingdom. It would have been well for them boldly to have set the example and have made 1000 grains a standard weight, and those above and below multiples or integral parts of it. It is a course which must sooner or later be adopted, even in this country, where we are so adverse to change. The subject of the weights alone would require almost a separate paper, I therefore hurry on to the more important consideration of the Pharmacopœia itself.

In commencing the consideration of the Pharmacopœia itself, I cannot do better than bring under your notice an extract from the preface regarding the arrangement of its subject matter, as the Committee on it describe more fully and accurately than I could the resolutions which they formed, and which they have well carried out in detail:—

"It was resolved that the British Pharmacopœia should consist of two Parts and an Appendix; the first Part to consist of the *Materia Medica*; the second of the *Preparations and Compounds*; and the Appendix of articles which are employed for the chemical processes in the second Part, but are not themselves used in medical practice, and of preparations solely intended for the chemical examination of the articles contained in the first and second Parts. The *materia medica* contains, in its simplest pharmaceutical form, every definite medicinal substance, whether obtainable in ordinary trade or prepared by the chemical processes in the second Part, which the Committee of the Council found, on careful inquiry, to be so far approved in practice as to be entitled to a place in a National Pharmacopœia. Under each article are given—1, a Latin pharmaceutical name by which it may be prescribed, and an English name for use in describing the processes in the second Part; 2, its definition, together with its chemical symbol, if it be a substance of definite composition, its botanical name if it be a plant, or its botanical source if procured from a plant, and also, in most cases, a reference to a correct figure of the plant, and a statement of the quarter whence the article is obtained; 3, the characters by which it may be distinguished from all other articles of the *materia medica*; 4, the tests by which it may be ascertained to be of due strength and free from known impurities or adulterations; and, 5, the preparations of which it is an active ingredient.

"The second Part comprises processes for the forms in which medicines may be used in extemporaneous prescriptions, and for articles in the *Materia Medica* obtained by chemical operations. The Committee of the Council took into consideration the question, whether the late transference of the manufacture of most chemicals from the pharmaceutical chemist to the chemical manufacturer might not be a reason for withdrawing a great part of the chemical processes from the Pharmacopœia. On mature consideration it was resolved to retain them; and the Council approved of that resolution. The contents and construction of the appendix do not require further explanation."

To give one or two examples of the *materia medica*, or first division of this work, I will select the first drug mentioned therein, gum acacia, and I find it described thus, "Acacia—Gum Arabic." One or more undetermined species of acacia linn. A gummy exudation from the stem; collected chiefly in Cordofan, in Eastern Africa, and imported from Alexandria.

Characters.—In spheroidal tears from half an inch

to an inch in length, nearly white, and opaque from numerous minute cracks, or in shining fragments; brittle, bland, and mucilaginous in taste, soluble in cold water. The solution forms, with subacetate of lead, an opaque white jelly.

Test.—The powder does not become blue on the addition of solution of iodine.

Preparation.—Mucilage.

On turning to the Dublin Pharmacopœia I find it thus mentioned, “Acacia vera Gum, Arabic tree. The gum—The true white gum is yielded by acacia verek; other species contribute to form the gum Arabic of commerce.”

Now, I have accidentally selected the substance which, of all others in the Dublin Pharmacopœia, is most fully described; in general, a line containing the official Latin, with the English name for same, and the part of the plant used in medicine, is all that is offered to us; for further information we must consult our dispensaries. On the other hand, the Materia Medica division of the British Pharmacopœia is so complete that a dispensatory is almost useless, or at least in the one case it is indispensable, in the other it is unnecessary to the pharmacien.

Again, in the Materia Medica of the Dublin Pharmacopœia, we had only mention made of the simple drugs and chemicals, and no reference whatever was made to the compounds for which formulæ were given; in the British Pharmacopœia we have not only every simple drug and chemical in use in medicine, but also every compound, for which a formula is given in the second division of the work, with its characters, tests for its purity, specific gravity, if a fluid; and principal preparations into which it enters.

Let us take Liquor Ammonia Acetatis. I find it thus described in the Dublin Pharmacopœia, “Ammonia acetatis liquor (ammonia acetatis aqua). Take of Sesqui-carbonate of Ammonia in fine powder, two ounces and a half, or a sufficient quantity. Dilute Acetic Acid, three pints. To the acid introduced into a bottle gradually add the sesqui-carbonate of ammonia to saturation, and dissolve by shaking, but without the aid of heat;” while in the British Pharmacopœia I find it first at page 15, where by the way it figures as ammonia acetatis liquor, and again at page 267 as liquor ammonia acetatis.

As the Pharmacopœia is arranged alphabetically, this disarrangement of the components of the name gives rise to needless confusion; the name applied in the Materia Medica division should have been carefully reproduced, without any change, in the second part.¹ To return, ammon. acet. liq. is described fully at page 15, thus: “Solution of Acetate of Ammonia, Acetate of Ammonia, NH₄ O, C₄ H₃ O₃, dissolved in water.

Characters.—A transparent colourless liquid, with a

saline taste. Treated with caustic potass it gives off an ammoniacal, and with sulphuric acid an acetous odour.

Tests.—Specific gravity 1.06. One fluid ounce treated with excess of hydrochloric acid, and evaporated to dryness by a water bath, leaves a residue of hydrochlorate of ammonia weighing 100 grains. It has no action on litmus, and is not rendered turbid by a solution of lime. Diluted with four volumes of water it gives no precipitate with chloride of barium or nitrate of silver. This solution contains about five times as much Acetate of Ammonia as Liquor Ammonia Acet. Lond., and six times as much as Liq. Ammon. Acet. Dub. and Edin.” Its preparation is thus described at page 267.—“Take of strong solution of ammonia three fluid ounces and a half, or a sufficiency; acetic acid, ten fluid ounces, or a sufficiency; mix gradually, and if the product is not neutral to test paper make it so by the addition of the proper quantity of either liquid.”

Now, Gentlemen, could anything be more explicit and satisfactory, both to the prescriber and compounder, than the manner in which this article has been described. It leaves nothing to be desired, and, in many cases, will, I have no doubt, produce marked improvement in compounding, more especially among English chemists not members of the Pharmaceutical Society, who, unfortunately too many of them, entirely ignorant of chemistry, or even of the first principles of their business, and it is a shame that it should be so, will have facilities for the study of the chemistry and natural history of the pharmacopœial products put before them, of which, if they do not take advantage, they will only have themselves to blame.

I should add that the London Pharmacopœia always gave more or less instructions for examining the purity of the drugs and chemicals therein mentioned; the Dublin Pharmacopœia never did. The reason of the difference is to a great extent obvious.

I find that I am taking up too much time in preliminary matter, and therefore must hurry on to that part of the paper which more especially interests you.

In the Materia Medica division of the Pharmacopœia we find that the following medicines have been added to the list of those contained in the Dublin Pharmacopœia:—

Acid. Phosphor, dil.	Lini Farina.
Ammon. Benzoas.	Lithiæ Carbonas.
___ Phosphas.	___ Citras.
Acid. Sulphurosum.	Mori Succus.
Aconitia.	Myristicæ Adeps.
Aconitum (the leaves and flowering tops).	Nectandra.
Aloes, Barbadoes.	Oleum Copaiba.
Anethum Graveolens.	___ Coriander.
Armoracia.	___ Rutæ.
Arnica Rad.	Podophylli Resina.
Atropia.	Podophyllum.
Aurantii, Aqua.	Potassæ Citras.
	___ Permanganas.

¹ Numerous instances of a similar kind occur throughout the work.

Balsamum Peruvianum.	Potassii Bromidum.
Beberix Sulphas.	Pterocarpus.
Bela.	Rosa Canina.
Cassia Fistula.	Sabadilla.
Cocculus Indicus.	Sambucus.
Collodion.	Artemisia Santonica.
Conii Fructus.	Santonine.
Cusparia.	Sapo Mollis.
Cusso.	Scammonii Radix.
Digitalinum.	Sevum preparatum.
Fel Bovinum.	Soda Caustica.
Ferri Arsenias.	Soda Arsenias.
___ et quinx Citras.	Stramonii Folia.
___ Perchloridi Liquor.	Styrax Præparatus.
___ Phosphas.	Sulphur Præcipitatum.
Filix.	Terebinthina Canadensis.
Jalapax Resina.	Ulums.
Kamela.	Veratria.

I will, in the first place, consider those articles of the *Materia Medica* which are not officinal in the London or Edinburgh Pharmacopœias, and afterwards proceed to the consideration of such as are derived from either of these sources.

Acid Sulphurosom, a solution of sulphurous acid in water, is an article which, though very little used in this part of the country, is, nevertheless, looked upon by many as a valuable external agent in skin affections of a parasitic character; it is, as you are aware, a powerful deoxidizing agent. One great disadvantage in using this preparation would arise from the uncertainty regarding its strength, as it does not keep well. I do not think that it possesses any great advantages over a solution of one of the alkaline hyposulphites, which could be extemporaneously prepared and be ordered of a uniform strength.

Aconitia is the new and much less elegant name for Aconitine, the active principle of the *Aconitum Napellus*. A formula is given for its preparation, and it is introduced to prepare the *Unguentum Aconitiæ*.

Arnica Root, introduced for the preparation of the Tincture of Arnica, has some reputation as a remedy in the treatment of bruises, &c. Heretofore the tincture of the flowers was invariably used for that purpose, and I have been informed with good effect. Dr. Garrod has recently instituted a series of experiments which seem conclusively to prove that the application of the tincture of arnica root to extravasated blood is not one whit more useful than that of plain spirit. Whether the tincture of the flowers would be a better preparation or not I do not know, but I am inclined to think that very little difference would be observable in their effects. I have never seen tincture of arnica ordered internally. Arnica root was in the *Materia Medica* of the old Dublin Pharmacopœia, from which it was expunged in the last edition.

Beberix Sulphas was first introduced to notice by

Dr. Douglas Maclagan of Edinburgh some twelve or fourteen years ago as a valuable tonic and antiperiodic; in fact, it was intended to take the place of quinine. It was extensively tried, but has almost fallen into disuse; it is not, I believe, to be compared to quinine in its antiperiodic qualities, and possesses no advantage, except that of cheapness, over that drug; while by the great majority of practitioners it was not found to answer their expectations, and was consequently discarded. Its appearance in the British Pharmacopœia will again bring it into notice.

Bela—The Indian Bael, has been strongly recommended as an agreeable astringent; particularly useful in diarrhœa and dysentery, especially in hot climates. It has not been much used in this country, and I do not think that it should have been placed in the *Materia Medica* until further trials had proved its efficacy. I have been told by those who have used it in India that it is a comparatively mild drug, and that no reliance should be placed on its use in acute dysentery, though it probably would be of use to those suffering from chronic diarrhœa, or a relaxed state of the bowels.

Collodion—I need scarcely refer to this well-known and valuable application; a formula has been given for its preparation.

Ammonia Benzoas and *Ammonia Phospha* are both introduced, they are little known and seldom used preparations. The former has no advantage over the Benzoic Acid except its greater solubility, and is used in similar cases; the latter, whatever may be its theoretic, has yet to prove its practical utility. It is said to be useful in some urinary and other diseases in which uric acid or urate of soda is formed.

Conii Fructus is introduced for the preparation of *Tinctura Conii*: although we know that the fruit, as well as the leaves of the plant, contains the conœia, I am at a loss to understand why the tincture is ordered to be prepared from the fruit, while for the preparation of the succus and extractum conii the leaves are directed to be used.

Kousso appears under the name of *Cusso*. I need not say anything concerning it, its use as an anthelmintic is well known.

Digitaline has been introduced, it will enable a dose of digitalis to be ordered in a small-sized pill; its uniformity of strength will be a recommendation in its favour; a formula has been given for its preparation; it is, however, so dangerous a medicine that most practitioners will hesitate to order it, more especially as the slightest overdose causes such violent nausea and prostration.

Fel Bovinum Purificatum, I need not more than mention, it is familiar to us all, and is worthy from its general use of a place in the Pharmacopœia.

Ferri Arsenias, as also *Sodæ Arsenias*, are both useful compounds, they can be readily ordered in pills, and their use in skin disease, more especially that of the

Arseniate of Iron, will be at once evident.

Ferri et Quinæ Citras, long known and extensively used, has many advantages over the ordinary preparations of quinine. I need not make any remarks concerning it; you will be glad to see its value at length recognized.

Ferri Phosphas, long used in America, has at length become naturalized with us. In the present day, when the use of phosphates has been so much recommended, and when most practitioners are ordering these medicines, this salt will prove a useful addition to our *Materia Medica*, though its insolubility in water will prevent its general adoption.

Kamela is the remedy so much vaunted for the cure of tape-worm; for a while, like kousso, it was in great demand, and largely used for that purpose. I do not think that it will prove of much greater value than some of our old and well-known remedies; and as it is now seldom used, I think that it might have been, with propriety, omitted from the *Pharmacopœia*.

Lithiæ Carbonas and Citras owe their introduction to the researches of Dr. Garrod, and have been recommended by him for gouty affections; the former, from its sparing solubility, is used more especially in the preparation of the effervescing bicarbonated water; the latter, from its solubility, is more in demand for mixtures, in which it can be ordered with other substances, which in all probability are more useful than the lithia itself.

Nectandra (Bebeeru Bark) is introduced for the preparation of the bebeerix sulphas, to which I have alluded.

Oil of Coriander has been heretofore but little used; it is pleasant to smell and taste, but inert, and not so useful as the great majority of our essential oils.

Podophyllum is introduced to prepare the Podophylli Resina, a preparation which was imported from America about three years ago, and has proved itself a good and useful cholagogue cathartic.

It is a useful addition to our *Materia Medica*. I could have wished that a formula for pills had been introduced with this medicine as a component part; an active purgative mass, of which five grains would have been a full dose, might have been ordered with advantage.

The chief, and indeed only, objection to the use of the resin of podophyllum is the depressing effect which too often follows its administration. This, however, would in some cases be an advantage.

Potassæ Citras is an elegant neutral salt.

Potassæ Permanganas is introduced for the preparation of the liquor potassæ permanganatis.

Potassii Bromidum was officinal in the London *Pharmacopœia* of 1836. It is a salt almost analogous in its uses and mode of administration to the iodide of potassium, over which it seems to possess little if any advantage.

Artemisia Santonica and *Santonine* are good and useful old-fashioned remedies, particularly useful in the treatment of ascarides, and worthy of a place among our vermifuges. The latter is the active principle of the former, and possesses all the active properties of the plant. It is almost tasteless.

Soda Caustica, in my opinion, has no advantage over the *Potassa Caustica*.

I have now hastily gone over in detail the new articles introduced into the *Materia Medica* of the British *Pharmacopœia*. In a paper of this kind it is quite evident that I could merely bring before your notice the more important characteristics of each.

I will now proceed to the consideration of those substances which, though not officinal in the Dublin, were so in either the Edinburgh or London *Pharmacopœia*.

Officinal in both the London and Edinburgh *Pharmacopœias*, we have *Barbadoes Aloes*, *Anethum Graveolens*, and *Armoracia*, for none of these can I see any great necessity.

The *Barbadoes Aloes* may be more active than the *Socotrine*, though this is denied on good authority. I think, however, that the latter would answer all the purposes for which aloes would be prescribed.

The *Anethum Graveolens* presents no advantage over the *Fennel* or *Aniseed*; while the use of *Sialogogues* has gone so much out of date that the *Armoracia* must fall back on its stimulant properties in order to deserve its resuscitation.

Aqua Aurantii Florum, *Balsamum Peruvianum*, and *Cassia Fistula* have been introduced. Of these I will merely remark that while the *Aqua Aurantii Florum* is perhaps one of the nicest vehicles with which we are acquainted for the administration of medicine, the *Balsam of Peru* appears to me to present no advantages over the *Balsam Tolu*, and the *Cassia Fistula* is almost useless, except to make up bulk.

Cusparia is a valuable addition to our non-astringent vegetable tonics.

Myristicæ Adeps, commonly called *Oil of Mace*, has been introduced; it is an elegant flavouring substance, which is all that can be said in its favour.

Oleum Copaibæ is a more elegant form than the *balsam copaiba* in which to administer that drug.

Oleum Rutæ is not much used, either as an anti-spasmodic or emmenagogue; it is inferior to many other similar preparations.

Pterocarpus Santalinus and *Rosa Canina* require little *Pharmacopœia* notice; the former is only used for its colour and flavour; the latter to make the *conserva rosæ*.

Sabadilla is introduced to prepare *veratria*.

Sambucus is used to prepare the *aqua sambuci*, which is said to be emollient.

Sapo Mollis is introduced, though I cannot see for what purpose.

London *Pharmacopœia* we have—

Atropia, an alkaloid so useful in affections of the eye, that it could not readily have been omitted.

Succus Mori, the only use of which is to make the syrupus mori; it has no medicinal properties, and might well have been omitted.

From the Edinburgh Pharmacopœia we have—

Cocculus Indicus, which makes an ointment particularly useful in some scalp affections.

Filix Mas, introduced for the preparation of the oil now called the liquid extract of male fern; you all know its great value as an anthelmintic.

Jalapæ Resina is a powerful cathartic, the alcoholic extract of radix jalapæ.

Lini Farina is described as “the seeds ground and deprived of the oil by expression.” I have no doubt that the crushed linseed, with the oil retained therein, acts much better and forms a nicer poultice.

Aconitum Napellus.—The leaves only of this plant have always been ordered by the Edinburgh, the root by the Dublin, while both were ordered by the London Pharmacopœia. In the British Pharmacopœia both are officinal; the leaves are used for the preparation of the extract, the root for the aconitine, tincture, and liniment of aconite. I cannot see why the root would not have answered all purposes.

The first preparations in the British Pharmacopœia are the acids. Of these little need be said. To make gallic acid, only one formula is given, the former and better of the two in the Ph.D. The hydrocyanic acid is of the same strength as formerly, containing two per cent of real acid. As the hydrochloric acid is ordered to be prepared, the resulting solution would contain very little of that gas. Directions should have been given to heat the mixture.

Dilute nitro-muriatic acid is ordered in place of the strong. Dilute phosphoric acid has been introduced from the Pharm. Lond.; it is a little stronger than that previously ordered. As a good useful medicine, which has been gradually getting into use, I am glad to see it in the Pharmacopœia.

The Aromatic Sulphuric Acid is not as strong as the same preparation in the Ph.D., which contained about one-third more sulphuric acid, nor as the dilute sulphuric add now ordered.

Formulæ have been given for the preparation of citric and tartaric adds respectively. Acidum sulphurosum has been introduced, and a formula given for its preparation. The dilute acids—viz., hydrochloric, nitric, and sulphuric, have been diluted so as to bring them to nearly the same strength in acid. The Dilute Hydrochloric Acid is now one-fourth stronger than formerly. Dilute nitro-muriatic acid is somewhat weaker than the other dilute adds in the proportion of 93 to 100.

A formula has been given for the preparation of Aconitia. The Alumen Exsiccatum, a comparatively unused preparation, has been retained.

Ammonia Bensoas and Ammonia Phosphas have

been introduced, as previously noticed. All the aromatic waters have been prepared by distillation from the fruit or seeds, except aqua menthæ piperitæ and aqua menthæ viridis, which are ordered to be made from the essential oils in a similar manner. The waters thus made will be more finely flavoured than those of the Ph.D., but not so easy of extemporaneous production; and I am afraid that in very few establishments will the waters be prepared in strict accordance with the directions of the Pharmacopœia.

Aqua Camphoræ, the old Mistura Camphoræ, is now ordered to be prepared by suspending pieces of camphor in a muslin bag in water. It will not be so good a preparation as the old.

A formula is given for Nitrate of Silver, which, did the apothecary adopt and do an extensive business therein, at the ordinary prices of the day, would largely curtail his profits.

Atropia and Beberia Sulphas have both formulæ given for their preparation.

The old Subnitrate of Bismuth, which has received so many names, has at length been called Bismuthum Album. As the carbonate of bismuth is also white and much used, though not officinal, mistakes might occur from this source, though no harm could thereby be done, and it would make little difference to either prescriber or patient, still even the slightest error should be avoided.

Calcis Hydras has been introduced in place of calx recens testa; its only use is to prepare the aqua calcis.

The Cataplasmata have been introduced from the Ph.L. almost word for word. They are cataplasma carbonis, conii, fermenti, lini, sinapis, sodæ chloratæ. As neither the medical man nor apothecary ever, at least in this country, make up cataplasms, I cannot see the use of their introduction.

A formula is given for preparing collodion.

The Confectio Piperosis is slightly changed. It has not so much pepper by one-fourth, and otherwise is not as nice as the old preparation. Confectio Scammonii fortunately has not undergone the slightest change, while the Confectio Sennæ has been improved.

Confect. Sulphur has one-sixth more sulph. and one-half less cr. tart.; the Confect Terebinth, a nasty preparation, remains unchanged.

In the Decoctions we find the decoctum aloes compositum unchanged. I do not think that it could have been improved. Decoctum cinchonæ flavæ has been introduced in place of decoctum cinchonæ, which was always made from the pale bark; and here I may add that in the British Pharmacopœia cinchona flava is invariably ordered where the pallida was previously. I think that this is a proper course. We all know that the cinchona flava contains a much larger quantity of quinia than any of the other barks. Decoctum granati is introduced from the Ph.L.; its properties as an anthelmintic have been much vaunted; the root, either

fresh or dry, is ordered. Most practitioners who have tried it consider the dry root to be inert. If there be a doubt in the matter, it would have been better to have ordered it fresh; a difficulty, however, would arise as to the procuring it in this state.

In the decoctum hæmatoxyli cinnamon has been advantageously ordered to flavour it.

Decoctum Pareiræ and decoctum taraxaci have been added to our list; the former is in pretty general use, the latter is generally preferred in the form of fluid extract, as the decoction spoils so readily. They were both officinal in the Ph.L.

A formula is given for the preparation of Digitaline.

In the Plasters, emplastrum calefaciens has been greatly changed, and to some extent improved. As ordered in the Ph.D. it never made a nice plaster. The principal objection to the present formula is, in my mind, that infusion of cantharides in boiling water is an uncertain preparation, and that the plaster so prepared will not be sufficiently irritant. Emplastrum galbani and emplastrum picis have been reintroduced from the Ph.L. I do not think much of either of them.

In the Enemas we have introduced enema aloes, forty grains to ten ounces, and enema opii, one-half drachm, tinctura opii to two ounces. The enema fœtidum has been very properly made six times as strong as the former preparation, and now has six drachms tincture of assafœtida to six ounces, while the enema catharticum is continued under the name of enema magnesiæ sulphatis. All the enemas, except the enema tobaci, are ordered to be made with mucilago amyli.

In the Extracts we have a large addition to our previous stock; it will be sufficient to name most of them. Many of them are very useless. We find extractum aconiti, anthe midis, calumbo, hæmatoxyli, jalapæ, kramerix, humali, nucis vomicæ, quassiæ stramonii, and taraxaci. We have now two watery extracts of aloes (Barbadoes and Socotrine); one would have been quite sufficient. We have extractum colchici and extractum colchici aceticum. The old favourite, extractum colocynthidis compositum, omitted from the last edition of the Ph.D., again comes before us. It is almost identical with the pilula colocynthidis composita, over which, to my mind, it possesses little advantages. It is weaker than the latter, and contains one grain of scammony in seven, while the pill contains one in three. Under the head of extracts we have the new liquid extracts, which are gradually rising in professional esteem. They are extractum belæ liquidum, the form in which the Indian bael previously referred to is ordered; the extractum cinchonæ flavæ liquidum, a valuable preparation, containing in one ounce the watery extract of four ounces of cinchona flava; the extractum ergotæ liquidum, a watery extract of the ergot, containing the active properties of one ounce of ergot in one ounce of the fluid, the oil having been previously removed by treating the

ergot with ether; extractum filicis liquidum, the so-called oil of male fern; extractum opii liquidum, containing one grain extractum opii in twenty—a nice preparation, an imitation of the liquor opii sedativus of Battley, about the same strength as tinctura opii, but differing from it in containing only the watery solution of the opium, hence it is said not to be so stimulating; extractum Pareiræ liquidum, containing in one fluid ounce the properties of an ounce of the drug; and extractum sarsæ liquidum, an elegant preparation, in which the active principle of two ounces of the sarsaparilla is contained in one ounce of the fluid, hence it is twice as strong as the ordinary fluid extract of sarsaparilla of the Dublin Pharmacopœia.

We have a formula for the Fel. Bovinum Purificatum; also formulæ for the preparation of Ferri Arsenias, Ferri et Quiniæ Citras, Ferri Bosphas; to each of these I have previously referred. We have no change of importance in the old preparations of iron.

In the mercurial preparations, hydragyrum cum magnesia has been omitted; the name of calomel has been retained, it is now also called the sub-chloride, while corrosive sublimate is the chloride. In writing prescriptions, the officinal and not the chemical name should be used, as otherwise serious mistakes might occur.

In the Infusions little change has been made. Cloves have been omitted in preparing the infusum aurantii. The infusum cinchonæ flavæ is ordered to be prepared with half the quantity of bark previously ordered in the infusum cinchonæ of the Dublin Pharmacopœia, in which also the pale bark was used.

Infusum cuspariæ and infusum cusso have been introduced. In ordering the latter I think that it would have been well to have ordered a full dose of kousso, and made eight ounces of the infusion. Infusum digitalis has been made half the strength it formerly was; it is now prepared with thirty grains digitalis leaves to ten ounces water. Infusum dulcamaræ, infusum lupuli, infusum serpentariæ, and infusum uvæ ursi have been introduced; none of them call for special notice.

The infusum gentianæ has been considerably changed; it is now directed to be prepared as in the Edinburgh Pharmacopœia. Proof spirit is poured upon the gentian, orange-peel, and coriander. After two hours the water is added, and after a further delay of two hours, the infusion is strained off. It thus takes four hours to make. I do not see why all the infusions might not have been prepared in the usual way, or why the infusion of gentian should be an exception; it will keep pretty well, and therefore will be always ready-made when wanted, but there are other infusions which might also have had spirit added with advantage. I think that all should have been prepared on one uniform plan.

A formula has been introduced for the preparation of the Jalapæ Resina.

In the Liniments, we have *linimentum aconiti*, a most powerful preparation. 20 oz. aconite root is ordered to be digested with 80 oz. spirit of wine, and 1 oz. camphor added to the percolated fluid. The directions for preparing this liniment are somewhat vague. *Linim. Belladonnæ* is also a very strong preparation made in a similar manner. In both these liniments the active principle of one ounce of the drug is supposed to be contained in the same quantity of the liniment. *Lin. Camphoræ* and *Lin. Camphoræ Compositum* retain their old places and formulæ. *Lin. Cantharidis* is made one-fourth stronger, and is further improved by its preparation with ether and acetic acid in place of olive-oil. Its name, however, should have been changed, as it is not now what is commonly called a liniment. *Liq. Cantharidis* or *Vesicous* would have been better. *Lin. Chloroform*, prepared by mixing equal parts of chloroform and camphor liniment, is an elegant preparation. *Lin. Iodi* is merely a very strong solution of iodine with iodide of potassium in spirit. One quarter of an ounce of iodine is dissolved in five ounces of rectified spirit; it will prove a useful external application.

Lin. Saponis is improved by the addition of oil of rosemary, and is now prepared with rectified spirits and a small quantity of water, in place of proof spirit heretofore ordered.

Lin. Terebinthinæ Aceticum might have been greatly improved, had the compilers of the *Pharmacopœia* adopted the formulæ given for St. John Long's liniment, which would have given them an elegant preparation, much used, and presenting many advantages.

In *Liquors*, *Liquor Ammoniaë Acetatis*, is, as you are already aware, six times stronger than that of the *Dublin Pharmacopœia*. In general, apothecaries in this country have been in the habit of preparing it of this strength, and diluting it when required for use; I cannot see any valid reason for increasing its strength so much.

The *Edinburgh Pharmacopœia* always ordered it to be prepared in the same manner as the *Dublin*, the *London* ordered it a little stronger.

The *Liquor Ammoniac fortior* is slightly stronger than that of the *Dublin Pharmacopœia*, its *sp. gr.* is now .891. *Liquor Arsenicalis* (Fowler's solution) is now prepared with eighty grains arsenious acid to twenty ounces (in place of seventy-two grains). It now contains four grains to one ounce in place of three three-fifths; this is a very proper change, I think that it might have been further improved by substituting a definite chemical compound such as the *Arseniate of Potash* for the merely mechanical solution here ordered. As, however, this preparation has been so long known and approved, I suppose the compilers of the *Pharmacopœia* thought it better not to make a change. *Liquor. Morphiaë Muriatis* is also changed, it now contains four grains in place of four and a half in the ounce. *Liquor. Atropiæ* is ordered to be prepared with four grains to

the ounce, this is too weak; eight grains to the ounce would have made a much more useful preparation. *Liquor. Calcis Saccharatus*, a new preparation, in which advantage has been taken of the increased solubility of lime when sugar is present, is twelve times stronger than the ordinary *Aquæ Calcis*. *Liquor. Ferri Perchloridi* is introduced for the preparation of the *Tinctura Ferri Perchloridi*, than which it is four times stronger. It will also be useful as a styptic. *Liquor. Plumbi Sub-Acetatis* is somewhat stronger than the old; its *sp. gr.* is 1.26. *Liquor. Potassæ* remains unchanged. *Liquor. Potassæ Permanganatis* has been introduced; its power as a disinfectant is so well known, and its topical use has been often attended with so much advantage, that it could not readily have been overlooked. *Liquor. Sodæ Arseniatis* is a solution of four grains *Anhydrous Arseniate of Soda* in one ounce of water. *Liquor. Strychninæ* is a solution of *Strychnia* of the same strength in *Hydrochloric Acid* and water with a little spirits.¹

I may add, that in the *Liquors* where dangerous substances are ordered, the strength of the solution is invariably four grains to the ounce. I cannot see why the tests for *Liquor. Potassæ Mistura Creasoti* has been introduced from the *Edinburgh Pharmacopœia*, it is an excellent form for the administration of creasote. *Mistura Guaiaci*, a useless preparation of *Guaiacum Resin*, *Sugar and Gum* has also been introduced, it was officinal in both the *London* and *Edinburgh Pharmacopœias*. *Mistura Scammony* is an elegant form of administering *Scammony*, little known in this country, but making a particularly nice mixture. It is prepared by rubbing up four grains of *Resin of Scammony* in two ounces of milk. It has long been officinal in the *Edinburgh Pharmacopœia*. The other mixtures remain almost unchanged.

I pass on to the consideration of the *Pills*, and find *Pilula Aloes Barbadosis* and *Pil. Aloes Socotrinæ*, in each of which preparations one grain of the respective aloes is present in every two grains of the pill mass. I cannot see the advantage of having two preparations so much alike, prescribers can, however, have their choice; though I think that in the great majority of instances in the country they will prefer the *Socotrine Aloes*, which they have been so long accustomed to use. *Pil. Aloes et Assafœtida* is a new preparation introduced from the *Edinburgh Pharmacopœia*, it is composed of equal parts of *Aloes*, *Soap*, and *Assafœtida*, and has been heretofore much in use. *Pil. Cambogiæ Co.* is a new and active preparation, containing one grain each of *Aloes* and *Camboge* in every five grains of the mass; it was offici-

¹ *Liquor. Arsenicalis*, &c., are given at foot of directions for their respective preparations, while those for *Liquor. Ammoniaë Acetatis*, *Liquor. Ammoniaë fortior*, &c., are given in the *Materia Medica* division.

nal in the London Pharmacopœia.¹ Pil. Colocynthis et Hyosциami has been introduced from the Edinburgh Pharmacopœia, and is a well-known and useful pill. Pil. Ferri Carbonatis, containing four grains Saccharated Carbonate of Iron in each five-grain pill, and Pil. Ferri Iodidi are both introduced, the former from the Edinburgh Pharmacopœia; the latter is new, and contains one grain Iodide of Iron in 3.6 grains of the pill mass. Pil. Saponis Composita is now called Pil. Opii, a change of which I do not approve, the old name was useful in many cases where the prescriber did not wish to appear to order opium. Oftentimes Pil. Opii grj. mitte xj. is ordered, that will now mean pills, containing one fifth of a grain of opium in each. Pil. Plumbi cum Opio is now introduced from the Edinburgh Pharmacopœia, it is a very useful and much used pill; in each four grains there will be three grains acetate of lead and a half grain of powdered opium. The other pill masses are so slightly, if at all changed, that none of them requires special notice.

Formulas have been introduced for the preparation of Plumbi Acetas, Podophylli Resina, Potassæ Chloras, Potassæ Citras, Potassæ Permanganas, and Potassii Bromidum, to these I need not refer, they are all prepared by the chemist on the large scale. Antimonial Powder is now easily prepared by mixing one ounce of the oxide of antimony (SbO_3) with two ounces of the precipitated phosphate of lime. In the former preparation we had a complicated mixture of the Oxide of Antimony, Antimonious Acid, Antimonite of Lime, and Phosphate of Lime.

As to the inertness of the latter there can be little doubt; whether the oxide of antimony will answer the purpose for which the antimonial powder is intended, I do not know. The James's Powder has in my opinion but little to fear from this rival. Pulvis Aromaticus has been improved, it now resembles the Pulvis Confectionis Aromatici, which, though not officinal, has long been in general use. Pulv. Cretæ Aromaticus has now one grain of prepared chalk in four, in place of one in three as formerly; the name has been changed from Compound to Aromatic Chalk Powder. Pulv. Cretæ Aromaticus c. Opio and Pulv. Ipecacuanhæ c. Opio have not been changed except in name.

Pulv. Kino Compositus has been introduced from the London Pharmacopœia, and contains one grain powdered opium in twenty grains; some powdered cinnamon is added as an aromatic with advantage. Pulv. Scammonii Compositus has now one grain of scammony in two grains of the powder, formerly it contained one in four, it also contains twice as much jalap as heretofore.

Pulv. Tragacanthæ Compositus is a new and inert pre-

paration, officinal in both London and Edinburgh Pharmacopœias.

Under the head of Spirits we have Spiritus Ætheris composed of one part ether and two parts of spirit, it was officinal in the Edinburgh Pharmacopœia.

Spirit. Ætheris Nitrosi, for the preparation of which a new and simple formula has been given.¹ Spirit. Cajuputi, an entirely new preparation, made from the oil by dissolving it in spirit; it will prove a good stimulant, easily miscible with other fluids. Spirit. Camphoræ, the old Tinctura Camphoræ, is now one-eighth weaker than formerly.

Spirit. Chloroform, a new preparation, consisting of one part chloroform dissolved in nineteen parts of rectified spirit, useful when we wish to order chloroform.

Spirit. Juniperi, composed of the oil of juniper dissolved in spirit, not nearly so aromatic as the former preparation of the Dublin Pharmacopœia. Spirit. Lavand. is introduced from the Edinburgh Pharmacopœia, and is merely a solution of the oil in spirit.

Spirit. Peppermint, Spirit. Rosmarini, and Spirit. Myristicæ correspond to their respective essences in the Dublin Pharmacopœia.

We have the Succus Corni, Succus Scoparii, and Succus Taraxaci, all new and valuable preparations.

We have Suppositories introduced, they were not officinal in any of the Pharmacopœias, they are Suppositoria Acidi Tannici, containing two grains tannic acid in each, and Suppositoria Morphia one-fourth grain in each, and are ordered to be prepared with white wax and lard. Cocoa Butter would in my mind have been a much better substance, and have given much less trouble to the compounder. Prescribers will in general prefer ordering Suppositories, with different ingredients and of different strengths, without reference to the Pharmacopœia.

The Syrups are little changed. Syrupus Aurantii Floris, Syrupus Ferri Phosphatis, Syrupus Mori, Syrupus Sennæ, Syrupus Papaveris, Syrupus Rheados, have been introduced; of these the three last-mentioned were officinal in both London and Edinburgh Pharmacopœias.

The Syrupus Mori was officinal in the London only, while the others are new. Syrupus Aurantii Floris, commonly called Syrup of Capillaire, is an elegant flavouring syrup; the Syrupus Ferri Phosphatis is a new and useful preparation, by far the best made in which the phosphate of iron can be administered; the Syrupus Mori is useless except as a colouring ingredient, and might well have been omitted; the Syrupus Sennæ is an agreeable and useful preparation; while I do not believe much in the medicinal properties of either the Syrupus

¹ Pil. Colocynthis Composita has been improved by the addition of an extra quantity of scammony, it now contains two grains of powdered scammony in every six grains, formerly it only contained one grain in the same quantity.

¹ Spirit. Ammonia Aromaticus, a nicer preparation than the old Sal Volatile, it scarcely contains so much ammonia. Spirit. Armoraciae, reintroduced from the London Pharmacopœia, it was omitted in the last edition of the Dublin, and contains the spirit of the armoracia combined with some good aromatics.

Papaveris or *Syrupus Rhœados*, and they are both very liable to vary in strength. The *Syrupus Aurantii* has been spoiled, it is now prepared by mixing the *tinctura aurantii* with simple syrup; the formula given in the Dublin Pharmacopœia made a much more elegant syrup. The *Syrupus Limonis* is a great improvement on the *Syrupus Acidi Citrici* (Dublin Pharmacopœia). The *Syrupus Ferri Iodidi* has been improved, as a thicker syrup is now ordered than that previously directed by the Dublin Pharmacopœia; it will consequently keep good for a much longer time.¹ None of the other syrups require special notice.

I now proceed to the consideration of the Tinctures. The *Tinctura Aconiti* is now one-fourth the strength of that previously ordered by the Dublin Pharmacopœia. In the note affixed to it is stated in error to be one-half the strength. *Tinctura Aloes*,² *Tinctura Benzoin Compositæ*, *Tinctura Castor*, *Tinctura Cinnamomi*, *Tinctura Guaiaci Ammoniata*, *Tinctura Kino*,³ *Tinctura Lobeliæ Ætherea*, *Tinctura Serpentariæ*, and *Tinctura Valerianæ Ammoniata*, have all been introduced from the Edinburgh and London Pharmacopœias, in both of which they were officinal. They require little comment, most of them have long been in general use among us, and are reproduced without any material alteration. *Tinctura Cinnamomi* is now made nearly one-half stronger than previously.⁴ *Tinctura Serpentariæ* has been made one-half stronger. *Tinctura Guaiaci Ammoniata* and *Tinctura Valerianæ Ammoniata*, the latter a good and useful antispasmodic, though not increased in strength, are improved by their preparation with the Aromatic Spirits of Ammonia, in place of Rectified Spirits and Liqueur Ammonia. *Tinctura Lupuli* of the Edinburgh Pharmacopœia has been substituted for the *Tinctura Lupulinæ*. *Tinctura Quinæ Composita* has been introduced from the London Pharmacopœia, it is an elegant preparation, in which the sulphate of quinine is dissolved by tincture of orange peel; too much quinine has, however, been ordered, eight grains to the ounce, which is rather more than the tincture will dissolve. *Tinctura Arnicæ Radicis*, *Tinctura Sabinæ*, and *Tinctura Senegæ*, not heretofore officinal in any of the Pharmacopœias, have been introduced. To the first I have already alluded, the others require no special mention. I think they should prove good and useful preparations. *Tinctura Cinchonæ Flavæ* has been substituted for the *Tinctura Cinchonæ*, in which the pale bark was used. Of the Tinctures of the Dublin Pharma-

copœia few have undergone material change. *Tinctura Belladonna* as now ordered is only half strength of the former Tinctures. *Tinctura Camphoræ* is now called *Spiritus Camphoræ*. *Tinctura Capsici* is ordered to be prepared with rectified in place of proof spirit, and is now only half its former strength. *Tinctura Cardamomi Composita* is slightly changed, it is more aromatic, and has raisins entering into its composition. *Tinctura Ferri Sesquichloridi* is now only one-fourth the strength of the former Tinctures of the Dublin Pharmacopœia. *Tinctura Iodi* as now ordered, while containing the same quantity of iodine, only contains one-fourth the quantity of iodide of potassium.

Tinctura Lavandulæ Compositæ is now coloured with sandal wool in place of cochineal; this is a very proper change, as this tincture is ordered to colour the Liqueur Arsenicalis. Heretofore the Arsenious Acid destroyed the colouring matter of the cochineal, as you are aware it would do with any animal matter, and a muddy solution, uncertain in colour, was the result; now no change will take place. I can see no necessity for two Tinctures of Lobelia, the old tincture made with rectified spirit might have been expunged when the ethereal was introduced. *Tinctura Opii Camphorata*, now called *Tinctura Camphoræ c. Opio*, contains two grains of opium in one ounce, formerly it contained two and one-third grains, otherwise it is the same. *Tinctura Zingiberis* is little more than half the strength of the former tincture.¹ *Tinctura Opii* remains unchanged, as do most of the other Tinctures.

The greater majority of the tinctures are ordered to be prepared by digesting the ingredients of which they are composed in spirit for forty-eight hours, and then percolating them. Though this method is very convenient for the apothecary, I do not think that as good Tinctures will thus be formed as by the previous method of digesting them for fourteen days. I may, however, be prejudiced in favour of the old method. The Pharmacopœia invariably orders that when the percolation is completed enough of the menstruum should be added to make up the original quantity of fluid, this will, of course, in many instances weaken materially the strength of the tincture. Hence, though the same quantity of the respective drugs be ordered, the new tinctures will be weaker than those formerly prepared.

Lozenges not heretofore in the Dublin or London Pharmacopœias are now introduced, they are -

Trochisci Acidi Tannici, having one-half grain, Tannic Acid in each lozenge.

Trochisci Bismuthi, having two grains Bismuth in each lozenge.

Trochisci Catechu, having nearly one one-fourth grain Catechu with a little Capsicum in each lozenge.

Trochisci Morphicæ, having one thirty-six grain Mor-

¹ It is now not so strong as formerly, as it does not contain more than three and a half grains to the drachm.

² *Tinctura Aloes* is ordered to be prepared from Socotrine Aloes and Extract of Liquorice, it contains eleven grains of aloes in one ounce.

³ *Tinctura Kino* is a good and useful astringent, difficult to keep from its readily becoming gelatinous.

⁴ It takes the place of *Tinctura Cinnamomi Composita*, a much more useful preparation, in which ginger and cardamom seeds were ordered with the cinnamon.

¹ *Tinctura Conii* is made from the fruit, formerly it was officinal in both the London and Edinburgh Pharmacopœias, and was prepared from the leaves, in the same proportion as now ordered.

phiæ Hydrochloras in each lozenge.

Trochisci Morphix et Ipecacuanhæ, having one thirty-six grains Morphix Hydrochloras, with one-twelfth grain P. Ipecac in each lozenge.

Trochisci Opii, having one-tenth grain Ext. Opium in each lozenge.

Of the above the last three were officinal in the Edinburgh Pharmacopœia. As these lozenges are all in general use, I think that it was wise to ensure uniformity of composition by giving formulæ for their preparation.

Among the Ointments we have the Unguentum Aconitiæ, Atropiæ, and Veratriæ, all new preparations, ordered to be prepared¹ by eight grains of the respective alkaloids, and adding one ounce of lard. Ung. Calomelanos, also now prepared by mixing eighty grains of Calomel with one ounce lard.

Ung. Gallæ c. Opio and Ung. Hydrargyri Ammoniati, both useful ointments, are introduced from the Edinburgh and London Pharmacopœias, the former is prepared by adding thirty-two grains powdered opium to one ounce of gall ointment.

Ung. Cocculi has been introduced from the Edinburgh, and the Ung. Belladonnæ from the London Pharmacopœia, the latter has very properly been made much stronger; it now has eighty grains of the extract mixed with one ounce lard, formerly it had only one drachm in four ounces. Ung. Terebinthinæ is a preparation almost similar to the Linim. Terebinthinæ, and might well have been omitted.

Ung. Antimonii Tartarati is now double its former strength. Ung. Hydrargyri Iodidi Rubri has very properly been reduced in strength, it now contains sixteen grains to one ounce, in place of one drachm to seven drachms.²

The other ointments have been little changed. Ung. Simplex is changed, though not improved in colour. Some of the ointments introduced into the Pharmacopœia are, I cannot help thinking, comparatively useless. I cannot see any use for the Ung. Atropiæ, and though the Ung. Calomelanos is useful in many cases, the prescriber would generally prefer to order whatever quantity of Calomel he thought fit in each particular case. The name Unguentum Hydrargyri Ammoniati should have been changed, the salt is a Chloro-Amidiæ of Mercury, and contains no Ammonia. Ung. Precipitatum Album, the ordinary name would have been much better.

A formula has been introduced for the preparation of Veratria.

We have introduced from the London and Edinburgh Pharmacopœia the Vinum Aloes, containing sixteen grains Aloes in one ounce; Vin. Antimoniale, containing two grains Tartar Emetic in one ounce, and

¹ Dissolving in spirit or rubbing up with oil.

² The formula for making Ung. Citrini is much improved, it will now make a good ointment, which will keep well.

Vin. Colchici, all well known preparations.

Vin. Ferri is introduced from the London Pharmacopœia, and contains eight grains Tartarated Iron in one ounce.

Vin. Ipecacuanhæ has been made one-fourth weaker, and Vin. Opii is the same strength as Tinct. Opii.

I need only name the preparations of Zine now officinal. They are Zinci Acetas, Zinci Carbonas. Zinci Chloridum, Zinci Oxidum, Zinci Sulphas, and Zinci Valerianas.

I have now finished the consideration of the preparations of the British Pharmacopœia, and need only call attention to the Appendix, which contains in one division the chemicals employed in the preparation of medicines, though not themselves used in medical practice; in the other, the tests ordered for the chemical analysis of the different preparations contained therein.

We miss from the British Pharmacopœia the following preparations heretofore officinal in the Dublin:—

Sodæ Acetas.	Ung. Cupri Subacet.
Morphiæ Acetas.	— Picis Liquid.
Calcii Chloridum.	— Plumbi Iodidi.
Zinci Chloridum.	Spt. Ammonix Fœtid.
Decoct. Dulcamaræ.	Empl. Ammoniac.
— Lini Comp.	Cupri Ammon. Sulph.
— Myrrhæ.	Syr. Croci.
— Pyrola.	— Morphix Acet.
— Uvæ Ursi.	— — Muriat.
Spt. Etheris Oleosus.	Liq. Antimonii Tartar- izati.
Infus. Menthæ Viridis.	Tinct. Ferri Acetatis.
— Juniperi.	— Cubebæ.
— Pareiræ.	— Guaiaci
— Simarubæ.	— Matico.
Arsenici et Hydrg. Hydriod.	Ferri Valerianas
— Liquor.	Quinæ —
Plumbi Iodidi.	Acetum Cantharidis.
Sulphur Iodatum.	— Colchici.
Mist. Ferri Aromat.	— Opii.
Hydrarg. c. Magnes.	— Scillæ.
Plumbi Nitras.	Acid. Acet. Camphorat.
Stanni Pulvis.	

There are also a few other substances seldom used and of little importance (as indeed are most of the foregoing) omitted from the Pharmacopœia. In looking over the list we will regret the loss of Hoffman's Ether, Donovan's Solution, Iodide of Lead, Aromatic Iron Mixture, Tincture of Acetate of Iron, and the Valerianate of Quinine from our Materia Medica. All the decoctions above-named, except that of Myrrh, which is a useless preparation, rarely ordered, appears in the British Pharmacopœia as Infusions. In the list of Infusions omitted, we find Inf. Menthæ Viridis, an agreeable menstruum in irritability of the stomach; Inf. Juniper,

which, as a good diuretic, was a nice vehicle in which to administer other medicines of a similar kind; Inf. Pareira, very properly now ordered in the form of Decoction, and Inf. Simarubæ, which was a comparatively useless preparation. In the Ointments, Ung. Picis Liquid, though a very nasty preparation, was often particularly useful, and Ung. Plumbi Iodidi was much used as a discutient, especially when applied to glandular enlargements.

I have in the foregoing paper endeavoured to place before you the more salient features of the British Pharmacopœia. After all, as you see, the changes have not been more extensive than we had a right to expect. As a rule the medicines when changed have been made weaker, and when a contrary course has been pursued, a special notice to that effect has been affixed. I regret that the Committee who prepared it should have seen fit to change the names of most of the alkaloids; thus Aconitia, Beberia, Quinia, have been introduced in place of the much more elegant names Beberina, Quinina, Aconitina. As the termination *ine* is used in chemistry to express an alkaloid, and most of us are accustomed to consider it as the active principle of the particular plant to which it may refer, I think that it would have been well not only to have retained it, but to have endeavoured to obtain uniformity by introducing it where it had not been hitherto in use; thus Morphina might have been called Morphina. Iodinium has been changed to the much less elegant Iodum; Liquor Chlorinii is now called Liq. Chlorig.

Other changes in nomenclature have also been adopted, to which time will not permit me to refer. Greater care should have been taken to prevent errors in the printing of the Pharmacopœia. At page 317, "Scammonizæ Resina" is translated "Resin of Jalap."

The Council in the latter part of their Preface say: "In conclusion, the Council warn all apothecaries and pharmaceutic chemists, that on the publication of the British Pharmacopœia it will be necessary, in order to discharge safely their duties to the public, that they should duly alter or destroy all pharmaceutic preparations made according to previous and now altered formula." I cannot but think that it would have been better had they fixed a day when the Pharmacopœia would have come into general use. They delayed the publication of it until a special Act of Parliament could be procured to compel its adoption, and surely they might readily have mentioned a date on and after which it would have been imperative upon all apothecaries and chemists to compound thereby; failing this, I think that it was the duty of the compounders of medicine to lose no time in complying with the order, they had legally no alternative but to do so. In all the first-class houses in the metropolis this course has been adopted. It would have been presumption on their part to have disobeyed the law, and have waited until they thought that the members of the profession had become acquainted with

its contents. The medical men are almost as well able to make themselves masters of its contents as are the apothecaries, and for those who cannot, or do not choose to do so, it is very easy for them to write Ph.D. quite as easy and much more regular than for those who wish to order the new formula to write Ph.Br. As you may have seen, owing to the strength of the great majority of the preparations when changed having been lessened, greater risk must necessarily be run by compounding from the Dublin, when the British Pharmacopœia is intended, than by pursuing the contrary course.

I have trespassed so long on your attention that I must now conclude, and thanking you for the patience with which you have listened to me, express my regret that the paper which I have now read was not more interesting, and that I could not, without wearying you, or reading another paper, have gone more fully into the details of the British Pharmacopœia.

Dr. Browne asked in reference to non-pharmacopœial medicines hitherto in use if the apothecaries would be obliged to abstain from keeping them.

Professor Ferguson remarked that as a free British subject he asserted his right to kill as he liked.

Mr. Grattan congratulated Dr. Whitaker on the paper which he had read.

It was proposed by Dr. Browne and seconded by Professor Ferguson that Dr. Whitaker with Messrs. Grattan and Pring be appointed a committee to draw up a synopsis of the changes most important to practitioners which have been introduced to the new Pharmacopœia.

It was also passed that Dr. Whitaker be requested to publish in a separate form the paper just read.

James Patterson, President

Pathological Room February 13th, 1864

Present, the President, Drs. Browne, Stewart, Whitaker, Little, Mr. Grattan, Drs. Cuming, D. Moore, W. MacCormac.

Mr. Grattan brought up the report of the Pharmacopœia Committee.

Dr. Browne made some further remarks on a previously reported case of hernia. On the 15th of the month, the man was seized with fæcal vomiting, and fæces began to appear at the wound. It was a case of ileus, and depended on a loaded state of the lower part of the intestine, as an enema gave relief. The wound afterwards became healthy and the man was well till the 28th. He had been for years subject to somewhat similar attacks. At the last mentioned date the former symptoms were renewed and aggravated. A poultice was placed on the abdomen, hydrocyanic acid was administered, and an enema given. On the 5th inst. he was discharged from [hospital]. There is

at present a fistulous opening in the locality of the wound. The man's safety depends on the regular administration of enemas.

Dr. Browne then brought forward a case of lithotomy by median section. He referred to another case which occurred in 1858 and in which he had removed a stone by a similar operation. He had also removed a foreign body in a similar manner.

The present patient had been treated two years ago for urinary irritation. Dr. Cuming found in the urine crystals of ammoniaco-magnesia phosphate, pus globules and crystals of oxalate of lime.

By the lithometer the calculus was found to measure $\frac{7}{8}$ of an inch. After removal the stone measured $3\frac{1}{4}$ inch in its short circumference and $3\frac{1}{2}$ inches in its long circumference. The diameter measured respectively $\frac{11}{8}$ ths, $\frac{10}{8}$ ths and $\frac{7}{8}$ ths inch. It weighed 5 drachms, and it consisted of oxalate of lime covered with some phosphatic deposits.

Three days after operation the urine came away by the urethra. In this case the density of the stone was an objection to the employment of lithotrity.

An advantage of this operation is the slight danger of wounding large vessels. There is also little danger of infiltration of urine. It avoids also wounding the prostate. This case shews the possibility of extracting a moderately large stone without making lateral section. In the old median operation the incision was made into the bulbous part of the urethra.

Dr. David Moore strongly condemned lithotrity.

Dr. Browne expressed himself in favour of lithotrity in proper cases.

James Patterson, President

20th February, 1864

Present, Drs. Patterson, Stewart, W. MacCormac, J. Reade, Keown, Cuming, H. Burden, D. Moore, Croskery, and Whitaker. Staff Surgeon Saunders was also present.

Mr. Croskery was unanimously elected a member of the Society.

Dr. Cuming read a paper "On recent researches on Inflammation."

Dr. Reade quite agreed with Dr. Cuming in thinking that the views formerly put forward on inflammation, were in many respects untenable, but did not see that the new theories led in anyway to an improvement or modification in the treatment thereof.

Dr. H. Burden thought that though, in the case related by Dr. Cuming, the fifth nerve was paralysed, still that the sympathetic nerve which accompanies it, might have been intact and thereby the inflammation of the conjunctiva have ensued. He also objected to the statement that the sympathetic nerve of the neck had been divided with little loss of nutrition to the parts thereby supplied.

Dr. W. MacCormac wished that Dr. Cuming would

continue the subject in another paper.

Dr. Keown asked Dr. Cuming how he thought the pain was occasioned where no nerve fibrils were interfered with.

Dr. Cuming in reply thought that pain might be occasioned by interference with a part over which some nerve fibril had control without any direct disturbance of the nerve itself. In answer to Dr. Burden he thought that the absence of laceration shewed that the sympathetic nerve had not been interfered with. Dr. Cuming also thought that while new views on the subject of inflammation would not change the local treatment that they might materially modify the remedies given internally.

James Patterson, President

[27th February, 1864]

Present, Dr. Patterson (President in the chair), Professor Ferguson, Dr. William MacCormac, Thompson, McWilliam, McCrea.

The President read a communication from Dr. McKesy.

Professor Ferguson then gave an account of a case of bronchial diphtheritis. The patient suffered from the symptoms of a cold on Tuesday. On Wednesday ... when ... saw him, there was great dyspnoea, full compressible and irregular pulse. Some substance was expectorated which on examination turned out to be a cast of the air passages. The cast appeared to reach from the larynx to the bifurcation of the trachea. The second cast appeared to him a second edition of the first.

The chest was resonant on percussion. The respiratory murmur was heard here and there, sonorous and sibilant rales. The fauces were reddened, but there was only a spot of lymph exudation visible in this region. The dyspnoea was not so great as would have been the case if the larynx had been affected, and there was no pneumonia.

Professor Ferguson connected the case with the reigning epidemic in which there is a tendency to lymph exudation from mucous membranes. He directed attention to the fact, that the exudation of lymph is not an occurrence confined to the passages of large diameter. He considered all these effusions of lymph were produced in the same diseases, and that the differences between them arose from differences in the form of the fever.

The President said that in this case there had been loss of voice for six months before the acute symptoms came on.

Dr. McWilliam said the former belief was that the disease was till lately unknown in Britain.

Professor Ferguson said that this idea arose from our ignorance of the disease. The present disease was asthenic whereas what had long ago been described Bulonnean was sthenic. He did not think that there

was any connection between the chronic and acute affection in the present case. He thought that exudate of this kind was invariably acute. Death in diphtheritic affections is caused by the fever.

James Patterson, President

Pathological Room

March 5th, 1864

Present, the President, Drs. Little (Lurgan), McWilliam, McCrea, Mr. Grattan, Dr. Browne.

The President reported that Sir H. Cairns had presented the petition in favour of retiring allowances to Dispensary Medical Officers.

Dr. Little then gave an account of three cases of inguinal hernia.

Dr. Browne suspected that the first case was varicocele of the round ligament. He thought the operation should generally be performed as soon as possible.

Dr. Browne presented his case of calculus. The wound has healed quickly and the case gets on well.

James Patterson, President

Belfast Newsletter 9 March 1864 p3

The Ulster Medical Society.—Dr. Patterson yesterday received the following letter from Sir Hugh Cairns:

19, Eaton Place, London.

7th March, 1864.

Dear Dr. Patterson

The newspapers would show you that I duly received and presented the Petition of the Ulster Medical Society to the House of Commons on the 1st last.

Ever faithfully, H. M. Cairns.

March 12th

Present, the President, Drs. Thompson, Reade, Stewart, D. Moore, McWilliam, Dill, Cuming, Croskery and Whitaker.

Dr. D. Moore brought forward a case of abdominal tumour of three years standing and gave an interesting account thereof. He entered as fully as possible into the history of the case and thought that the swelling was due to the enlargement of the liver and spleen by the deposition of tubercle therein; he also stated that tubercle was present in the lungs and that the effusion formed no part of the abdominal swelling.

Dr. Reade referred to the difficulty of diagnosis in such cases, and while he thought that tubercle might have been deposited in the liver did not believe that the great expansion of the lower ribs was due thereto. He referred to a post-mortem of a case of phthisis, in which great dullness was present at base of both lungs of the patient, when it was found that the liver was fatty and enlarged, thereby distending the ribs. He had little doubt that in the present case, effusion

of fluid had taken place. As to treatment he thought that painting with Iodine, Chalybeates internally, with nutritious diet gave the best chance of success.

Dr. Cuming thought that no treatment would be of any avail. He agreed with Dr. Reade in thinking that the difficulties of diagnosis were almost insuperable. He could not attribute the whole of the tumour to the liver and believed that the spleen was also engaged. He also thought that some fluid was present, though not in sufficient quantity to be of any importance.

The President referred to a case almost similar to that of Dr. D. Moore, which terminated fatally, treatment similar to that recommended by Dr. Reade had been tried, but was of no avail.

James Patterson, President

Pathological Room

March 19th, 1864

Present, the President, Drs. D. Moore, Gribbin, Whitaker, McCrea.

Dr. Whitaker introduced the corrected proof of the Summary of the New Pharmacopœia. It was resolved that Dr. Whitaker send a copy of the Summary to members of the Society, with a request that they will specify the Pharmacopœia according to which they wish each prescription to be filled.

James Patterson, President

Pathological Room

April 2nd, 1864

Present, the President, Drs. D. Moore, W. MacCormac, Whitaker, McCrea, and Mr. Brooke the celebrated tragedian who was introduced by Dr. Moore.

Dr. Moore exhibited a patient in whom the scalp had been severely injured. The bone beneath had also necrosed. The patient was insensible when brought into hospital, but under proper treatment gradually recovered.

Dr. Moore lately removed the dead bone which included a part of the internal table. Dr. Moore drew attention to the pulsation of the brain, which he described as evidenced by the pulsatile issue of blood from the gap in the bone. Dr. Moore also mentioned a case in which the whole of the upper surface of the calvarium had been denuded. Granulations were springing up from the whole surface of the wound.

Dr. Moore then exhibited a case of ganglion of the wrist. The ganglion had had removed from it a considerable number of cartilaginous bodies, and was still discharging them.

Dr. W. MacCormac enquired why Dr. Moore had made two incisions instead of one and why he did not try force as a means of expulsion.

Dr. D. Moore gave an account of a remarkable case of congenital syphilis.

James Patterson, President

Pathological Room

April 9th, 1864

Present, the President, Professor Ferguson, Drs. W. MacCormac, Croskery, Whitaker, McCrea.

Dr. Whitaker read a paper by Dr. Scott of Aghnacloy on the curative effects of Glycerine and Bismuth.

Professor Ferguson thought that the effect of the mixture was merely mechanical.

Dr. W. MacCormac mentioned the use of Bismuth as an injection in certain cases of glands.

Dr. Moore brought forward a peculiar case of accident which required amputation of the arm. The forearm had been severely lacerated. An attempt had been made to save the limb but the recurrence of hæmorrhage and a swollen state of the limb necessitated amputation. Since the operation the patient has had rigors. The operation was performed four days after the accident.

Professor Ferguson enquired what were Dr. Moore's reasons for anticipating the favourable result from the attempt to save the limb.

Dr. Moore stated that although the ulna was destroyed, the radius was intact, the skin on the radial side of the arm was unhurt, and the man had the use of the thumb and two fingers. Under these circumstances he thought it mete to give the patient a chance of keeping his arm.

James Patterson, President

April 16th, 1864

Present, the President, Drs. Moore, Stewart, Gribbin and Whitaker.

Dr. Moore brought forward a case of necrosis of the bones of the carpus which occurred in a woman of about 40 years of age.

He entered into the history of the case, and stated that a swelling had taken place on the back of the wrist about 3 or 4 years, that matter had formed therein, fistulous opening ensued, and the hand became flexed and entirely useless. He removed the joint and the parts healed by the first intention.

Dr. Moore then referred to a case of fibro-cellular tumour of the tongue upon which he intended to operate in a few days.

Dr. Moore then shewed a tumour which he had recently removed from a gentleman's brow, and entered into the history, and treatment he adopted in such cases.

James Patterson, President

April 23rd, 1864

Present, the President, Drs. Stewart, McCrea, Ross, McWilliam, D. Moore, Croskery, Moore and Whitaker. Dr. Rea (H.P.) proposed and seconded by Drs. McCrea and Whitaker.

Dr. Whitaker moved and Dr. McWilliam seconded "That a special meeting of the Society be called for next Saturday to consider the present condition of

the Society." Carried.

Dr. Ross read a report of a case of intra-uterine polypies. He detailed the steps of the operation, which was successful.

Dr. Moore referred to the Laminaria Digitata as particularly useful in dilating the os.

Dr. McCrea asked what was the appearance of the tumour.

Dr. Ross stated that the tumour consisted of [calx?] surrounded by numerous fibrils.

Dr. Moore referred to a case of disease of the tarsus, in which he had removed all the bones except the astragalus and os calcis. He shewed the patient. He also stated that he intends to cut the Tendo Achilles.

Dr. Moore shewed the case of injury of the skull to which he had formerly called attention.

T.R., V.P.

April 30th, 1864

Present, Dr. Reade (Vice President, in the chair), Professor Ferguson, Drs. McCrea, Gribbin, McWilliam, Warwick, Smith, D. Moore, Croskery, Cuming, Stewart, and Whitaker.

The election of Dr. Rea was postponed till Saturday the 7th inst.

Professor Ferguson referred to the little interest that appeared to be taken in the proceedings of the Society, and regretted that the attendance of members on so important an occasion should be so limited.

He wished to know why the meetings of the Society should be so badly attended as they had latterly been. A desultory conversation ensued in which most of the members took part.

Dr. Smith apologised for his non-arrival at the time for commencing the meeting and entered into a general statement of the pecuniary condition of the Society.

Professor Ferguson moved, and Dr. McCrea seconded, "That a special meeting of the Society be called for Thursday next at 3p.m. to be held in the library of the General Hospital to receive a report from Council on the state of the Society and that the notice be marked 'most urgent'".

Drs. Stewart and Cuming were appointed Auditors. Carried.

James Patterson, President

May 5th, 1864

(Special Meeting)

Present, Drs. Thomas Reade (V.P. in the chair), Stewart, Smyth, D. Moore, W. MacCormac, Gribbin, Croskery, J. W. T. Smith, Brice Smyth, and Whitaker.

Dr. Stewart moved, and Dr. Brice Smyth seconded "That the report from Council be received and adopted."

Dr. Smyth (Sec) entered into a detailed statement of

Ulster Medical Society
Session 1863–1864
President James Patterson

the accounts of the Society.

Dr. W. MacCormac moved, and Dr. D. Moore seconded “That the ordinary subscription for town members be reduced to one guinea.” Amendment put and lost. Original motion put and carried.

Dr. Stewart moved and Dr. J. W. T. Smith seconded “That the Council be recommended to dispense with the services of John McCann and terminate their subscription to the two local papers.”

Drs. William MacCormac, J. W. T. Smith and David Moore were appointed to review the books and journals of the Society.

May 7th, 1864 [Annual Meeting]

Present, Drs. Patterson, President in the chair, Moore, W. MacCormac, McCrea, D. Moore, Smith, Cuming, Whitaker, B. Smyth, Surgeon Croskery, Gribbin, John Smyth and Whitaker.

The minutes of the meeting of the 30th and of the last Annual Meeting were read and confirmed.

Dr. H. P. Rea was unanimously elected a member of the Society.

Dr. McCrea moved and Dr. D. Moore seconded “That the minutes of special meeting be confirmed.”

Dr. W. MacCormac moved and Dr. Whitaker seconded “That the minutes of last meeting so far as the annual subscription are concerned be not confirmed. That the subscription for ordinary members be one guinea per annum for the future, and that life members do pay half a guinea subscription.”

Original motion was withdrawn, amendment carried unanimously.

The following gentleman were elected office bearers for the ensuing year.

President

Dr. Stewart

Vice Presidents [Town]

Dr. Moore, Dr. Smith (J. W. T. S.)

Do (Country)

Dr. Scott and Graves

Members of Council

Drs. Drennan, H. S. Ferguson, B. Smyth, Dill, Wheeler and Ross

Treasurer

Dr. Cuming

Secretaries

Drs. Whitaker and Croskery were elected.

Surgeon Gribbin was requested to see to the circulation of the Journals.

Drs. Wheeler and John Smyth moved and seconded a vote of thanks to the President which was carried by acclamation.

The President returned thanks in suitable terms. A vote of thanks was moved and seconded to the Sec-

retary and Treasurer for their services during the past year.

Robert Stewart, Chairman
6th May 1865

Ulster Medical Society
Session 1864–1865
President Robert Stewart

ULSTER MEDICAL SOCIETY

SESSION 1864–65

June 4th, 1864

Present, Drs. Stewart (President in the chair), Patterson, W. MacCormac, Moore and Whitaker.

There was no business transacted.

July 2nd, 1864

Present, Drs. Stewart (President in the chair), Patterson, JW Smith, Cuming, D. Moore and Whitaker.

A desultory conversation took place regarding the best means to bring the Society into good working order.

August 6th, 1864

Present, Drs. Stewart (President in the chair), Browne, W. MacCormac, Rea, Moore, McCrea, and Whitaker.

Minutes of last meeting read and confirmed.

A communication was read from Mr. H. Hyndman with regard to M. Rayouot whom he described as an unqualified practitioner calling himself Dr. Medicine. After some discussion Secretary was directed to write to Mr. Hyndman declining on the part of the Society to interfere in the matter.

September 3rd, 1864

Present, Drs. Stewart (President in the chair), McWilliam, H. Burden, H. P. Rea, Gribbin, and Whitaker.

The minutes of last meeting having been read and confirmed, ...

COMPILER'S NOTE

The Minute Book here contains a number of empty pages. Given the existing apathy, it seems likely that there were no meetings in that time.

THE ULSTER MEDICAL SOCIETY.
THE ANNIVERSARY DINNER.¹

The anniversary dinner of the members of the above Society took place on the 1st instant, in Mr. Thompson's rooms, Belfast. Amongst those present were—Dr. Stewart, President of the Society, in the chair; Dr. MacCormac, Professor Ferguson, Q.C.B.; Dr. James Moore, Vice-President; Dr. Pirrie, Dr. Cuming, Treasurer; Dr. Harkin, Dr. McCrea, Dr. David Moore, Dr. William MacCormac, Dr. Michael McGee, Dr. Whitaker, Secretary; Dr. McWilliam, Surgeon John Smyth, Dr. H. Rea.

Letters of apology were read from the medical officers of the garrison—Staff Surgeon-Major Docker and

Assist.-Surgeon Bayfield—both of whom had been specially invited as guests, but who much regretted that prior engagements prevented them from being present on this occasion. Dr. T. Reade, Dr. Drennan, and Surgeon Gribbin were also unavoidably obliged to be absent. The usual loyal toasts having been given, they were succeeded by "The Medical Departments of the Army and Navy." The President in proposing this toast said, he regretted much that there were no members of either branch of the service present this evening to call upon to speak to it; he could not, however, permit the opportunity to pass by without observing that their brethren in the army particularly had still every reason to feel deeply aggrieved and wronged in respect of the inexcusable conduct of the military authorities, in regard to the Queen's Warrant of 1858, having rendered it to all intents and purposes a dead letter, the consequence of which was, that candidates of any spirit were thus prevented from coming forward in sufficient numbers to fill the vacancies in existence, and not only this, but to cause both surgeons and assistant-surgeons to resign their commissions. This was the worst policy imaginable, and sooner or later it would be found to be so (hear).

"The Medical Faculties of the Queen's Colleges," which was very ably spoken to by Professor Ferguson.

"The Medical Charities of Belfast," responded to by Dr. Pirrie and Dr. William MacCormac, on behalf of the General Hospital; Dr. David Moore for the Dispensaries; and Dr. H. Rea for the Belfast Union Hospital.

"The Ulster Medical Society," responded to by the Vice-President of the Society.

"The Royal Medical Benevolent Fund Society of Ireland." Dr. Cuming, having been generally called upon, replied to this toast very effectively.

"The Officers of the Society," responded to by the several officials present.

"Our Absent Members, and, in particular, Dr. Patterson," one of the most valued members of the Society, whose absence on the present occasion, owing to a recent severe domestic affliction, was much sympathised with by all present.

"The General Practitioners of Belfast, coupled with the name of Surgeon Smyth," who responded in an excellent speech.

Some further toasts having been given by the members generally during the evening, Dr. M. McGee, of the number, who spoke very largely and eloquently on several subjects, the company separated much pleased with the entire arrangements of the day, and the very satisfactory manner in which Mr. Thompson had fulfilled his important part upon the present occasion.

April 23rd, 1865

Present, Drs. Stewart (President in the chair), Moore, Gribbin, W. MacCormac, D. Moore, Rea, Surgeon N. Moore and Whitaker.

¹ [Dublin Medical Press, 1864, November 16, p499.]

As there was no business to be transacted, a desultory conversation took place among the members as regards the position of the Society etc. after which—

Drs. D. Moore and H. P. Rea were elected Auditors of accounts.

Surgeon N. Moore resigned his appointment as Librarian to the Society, as he found that his time was so fully occupied that he could not properly attend to the duties of the office.

Robert Stewart, Chairman
6th May, 1865

May 6th, 1865 [Annual Meeting]

Present, Drs. Stewart (President in the chair), Patterson, W. MacCormac, McCrea, D. Moore, Cuming, Surgeons Nevin Moore, Gribbin, and Whitaker.

The minutes of the last Annual Meeting and of the 23rd ult. were read and confirmed.

The Accounts for the past year having been duly audited were passed. The Treasurer made some remarks on the financial position of the Society, and the probable result of the next year's income.

President

Dr. Moore

Vice Presidents

Drs. MacCormac (W.) and Patterson

Dr. MacCormac resigned the office. Dr. Drennan was elected in loco.

Country Vice Presidents

Dr. Scott and Moore

Members of Council

Drs. Whitaker, Harkin, H. S. Ferguson, D. Moore, Browne and Murney

Dr. MacCormac moved and Dr. Patterson seconded that the Treasurer be requested to continue his valuable services for the ensuing year.

Dr. Whitaker then tendered his resignation.

Dr. Cuming moved and Surgeon Gribbin seconded the appointment of Dr. McCrea as Secretary. Carried unanimously.

Dr. MacCormac moved and Dr. D. Moore seconded "That Mr. Richard Watson, the house steward of the hospital, be elected librarian at a salary of £10 per annum." Carried unanimously.

Dr. Cuming moved and Dr. W. MacCormac seconded "The President leave the Chair and Dr. Patterson take it." A Vote of thanks to Dr. Stewart for his unwearied attention to the interests of the Society and the exertions which he has made during his year of office.

Robert Stewart, Chairman
2nd September 1865

ULSTER MEDICAL SOCIETY

SESSION 1865–66

462 Notice of meeting on 3rd June 1865

President.

Dr. Moore.

Vice-Presidents.

Dr. Drennan.

Dr. Moore (Glenarm).

Dr. Patterson.

Dr. Scott (Aughnacloy).

Members of Council.

Dr. Browne.

Dr. Whitaker.

Dr. Murney.

Dr. D. Moore.

Dr. H. S. Ferguson.

Dr. Harkin.

Treasurer.

Dr. Cuming.

Secretary.

Dr. M'Crea.

The Second Meeting of the present Session will be held in the General Hospital, on Saturday, the 3rd of June, at Three o'clock, P.M.

Business

Dr. D. Moore will introduce a child with a large tumour on the side of the chest.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretaries, with their qualifications and Subscription.

Signed by order,

John M'Crea, M.D.
Secretary.

Belfast, 1st June, 1865.

464 Letter (presumably addressed to the members).

June 2, 1865.

Sir

The Council of the Ulster Medical Society is anxious to secure a regular distribution of the Periodicals.

I am, therefore, instructed to request that you will be so good as to inform the Librarian or the Secretary of any irregularity that may occur in your supply.

I am,
Your obedient Servant,
John M'Crea, M.D.
Secretary.

General Hospital

June 3rd, 1865

Second Meeting

Present, the President, Drs. Reade, D. Moore, N. Moore, McCrea, Stewart.

The President returned thanks for the honour the Society had conferred on him.

Dr. D. Moore introduced a child with a large tumour on the upper part of the side of the chest. The tumour commenced about 14 months ago in the axilla. At first it subsided but afterwards increased for 5 months. During the next 4 months it was about the size of a hen's egg. At this period it was open. It has been increasing for six weeks with great rapidity. An exploratory opening lately made gave exit to serous fluid. He considered that it consisted of cysts and might become malignant. He therefore considered the question of removing it worth consideration.

Dr. Reade would have no hesitation about removing it. Explore first and if contents be serous withdraw them. This would diminish the size of the tumour and facilitate its removal.

Dr. Reade also mentioned a remarkable case in which he had removed an enormous tumour from the side of a child's chest.

The President considered it a multi-locular tumour with a tendency to encephaloid degeneration. Make a number of openings in it; reduce the size of it by this means. Explore with the finger inserted in one of the openings. Avoid the axillary vein which is often connected with tumours like this.

Dr. D. N. Moore looked on the tumour as non-malignant.

Dr. D. Moore: The child's age, the absence of adhesions, the mobility of the skin, the freedom from affection of the cervical glands are against the idea that the tumour is malignant.

On the motion of Dr. Stewart seconded by Dr. D. Moore it was resolved that the salary due the late librarian be paid.

Robert Stewart, Chairman
2nd September 1865

467 Notice of meeting on 5th August 1865

[Top of page missing.]

Secretary.

Dr. M'Crea.

The Fourth Meeting of the Society will be held in the General Hospital, on Saturday, the 5th of August, at Three o'clock, P.M.

Business

The Coronership.

The vacancy in the Medical Inspectorship of Factories.

Dr. Ross's Paper on "The Fevers of Ireland."

The President will exhibit an enormous Tumor removed from a Lady's Breast.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John M'Crea, M.D., Secretary.
Belfast, 3rd August, 1865.

General Hospital

August 5th, 1865

Fourth Meeting

Present, the President, Drs. Patterson, Stewart, Reade, D. Moore, B. Smyth, McCrea, Holden (visitor).

The President brought under consideration the Coronership, and a notice from Mr. Baker that an appointment of assistant to Dr. Thompson, the Medical Inspector of Factories would shortly be made.

The President shewed an encephaloid tumour of the mamma, which he had removed by enucleation and without the assistance of chloroform. The wound had healed by the first intention almost entirely. The tumour had been nearly nine years growing.

Dr. D. Moore remarked on the absence of affection of the lymphatics, and said that this more common the case in encephaloid than in schirrhous affections.

Dr. Reade thought it worth considering whether or not an operation ought to be performed even in

necessarily fatal cases, in order to make the mode of death less painful. Dr. Reade was not prepared to subscribe to Dr. D. Moore's opinion that affection of the glands was less likely in encephaloid.

Dr. Reade called attention to a circular asking for subscriptions for a monument to the late Professor Ferguson. He thought that a public meeting should have been summoned.

Robert Stewart, Chairman
2nd September 1865

468 Notice of meeting on 2nd September 1865

[Top of page missing.]

Secretary.

Dr. M'Crea.

The Fifth Meeting of the Society will be held in the General Hospital, on Saturday, the 2nd of September, at Three o'clock, P.M.

Business

Dr. Smith will shew a diseased Brain.

Dr. Ross will read a paper on the "The Fevers of Ireland."

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John M'Crea, M.D.
Secretary.

Belfast, 1st September, 1865.

**General Hospital
September 2nd, 1865
Fifth Meeting**

Present, Drs. Stewart (Chairman), Smith, Ross, Gribbin, Holden, McCrea.

The man was admitted to hospital on April 1st of this year and went out. He was re-admitted on 17th June. He had acute pain over right temporal bone. Tongue thrust to right side. Ptosis of right eye. Pain diminished under use of Iodide of Potassium but still there was slight difficulty of speech. On August 1st readmitted. Health bad. Hiccup. Great constipation. Muscles of deglutition much affected. His left side was weak. Paralysis of left arm but not complete. Died of asthenia on August 27th. From the incompleteness of the paralysis a tumour at base of brain was suspected.

On P.M. adhesion of cerebellum at junction with Crus to petrous bone just below internal auditory

meatus. A tumour on medulla oblongata. This pressed on eighth, seventh and ninth pairs of nerves. Hypoglossal obliterated. The tumour was an enlargement of one half of the medulla oblongata.

James Moore M.D.

465 Letter to members

September 22, 1865

Sir

A Special Meeting of the Society will be held at the General Hospital, on Saturday, the 23rd instant, to consider the following advertisement:—

Belfast Union

Wanted, a legally qualified Resident Medical Officer for the Infirmary etc. of the Workhouse at a Salary of £45 per annum with first-class rations.

Testimonials to be lodged with me before Eleven o'clock A.M. on Tuesday the 3 proximo. when personal attendance of the candidate is required.

Information as to duties, &c., may be known on application to Dr. Seaton Reid.

(By order of the Board),

William F. Boyce, Clerk of the Union
Board-room, Workhouse, Sept. 20, 1865.

John M'Crea, M.D., Secretary.

**General Hospital
September 23rd, 1865
Special Meeting**

Present, the President, Drs. Stewart, Patterson, Drennan, Cuming, MacCormac, Whitaker, D. N. Moore, D. Moore, McCrea, Murray, Dill, Gribbin.

The following advertisement was read

Belfast Union

Wanted, a legally qualified Resident Medical Officer for the infirmary etc. of the Workhouse at a Salary of £45 per annum with first-class rations. Testimonials to be lodged with me before 11 o'clock a.m. on Tuesday the 3 prox. when personal attendance of the candidate is required.

It was moved by Dr. Patterson and seconded by Dr. Stewart and unanimously resolved "That the Society express its decided opinion that the remuneration proposed is entirely insufficient to recompense such Medical Officer for duties requiring his entire time, and that the offer of such salary is derogatory to the Medical Profession at large."

Dr. Drennan moved and Dr. Gribbin seconded

That the resolution be published in an advertisement in the Belfast papers of Monday and Tuesday.

James Moore M.D.

Advertisement¹

ULSTER MEDICAL SOCIETY.

A Special Meeting of the above Society

was held on Saturday, September 28rd, Dr. Moore, President, in the chair.

An advertisement issued by the Belfast Board of Guardians, announcing that a legally qualified Resident Medical Officer is wanted for the Workhouse Infirmary, and offering a salary of £45 per annum for such office having been read, it was resolved—

“That the Society express its decided opinion that the remuneration proposed is entirely insufficient to recompense such Medical Officer for duties requiring his entire time, and that the offer of such salary is derogatory to the Medical Profession at large.”

COMPILER'S NOTE

The four extracts below provide some background to the advertisement and responses from others.

BELFAST BOARD OF GUARDIANS
25 July 1865
AN ADDITIONAL OFFICER.²

Mr. Gaffikin said he thought Mr. Newett, the resident surgeon and apothecary, had too much by far to do. They had two eminent consulting physicians, but then the actual work which devolved upon Mr. Newett was excessive, and immediate arrangements should be made for the employment of another permanent assistant in that department. The duties of the situation were much heavier now than when the gentleman was first appointed, and there no less than 93 cases admitted to hospital last week. It was said that, with the advance of wages, the number of applications for admission to the hospital would diminish. Now the converse of this seemed to be the case, for the admissions had for some years past annually increased. It did not matter what wages a man had if when or his family became ill, he had nothing past him. The average cases per week in '61 were 50, and for aggregate cases for the year were 553; in '62 there were 77 cases weekly, and a total of 683 for the year; in '63 there were 99 cases weekly, and 752 were attended to during the year; in '64 the cases were 94 weekly, and 765 for the whole year. For the present year there had been 96 per week.

The Chairman thought the consideration of the matter should be deferred till the return of Dr. M'Gee, who was at present in the Isle of Guernsey. Dr. M'Gee had made inquiries, and had a report to submit on the subject.

The matter then dropped.

¹ [Medical Press Advertiser, Second Series, 1865, September 27.]

² [Belfast News-letter, 1865, July 26.]

BELFAST BOARD OF GUARDIANS

5 September 1865

REPORT OF THE HOSPITAL COMMITTEE.¹

Mr. Gaffikin then read the following report of the above committee:—

“We, your committee summoned to inquire and report on the medical staff of the workhouse, met today, when there were present—Messrs W. M'Gee, M.D., Thomas Gaffikin, James Entwhistle, and Robert Carlisle—John Hamill, Esq., occupying the chair.

After mature deliberation, and having also considered the letters of Drs. Reid and Mulholland, we beg leave to report that, in accordance with the views set forth in Dr. Reid's letter of the 22nd May, 1865, we recommend the appointment of an additional legally qualified resident medical officer, at a salary of £45 per annum, with rations and quarters. The details of his duties to be as set forth in the 1st, 2nd, 4th, and 5th paragraphs of Dr. Reid's letter.”

[In the discussion, Mr. Gaffikin said] Since that time [25 July] Dr. Newett had taken ill, and they had two young men employed in his place, doing the same work as he himself had done. Surely, with nearly 1,000 sick, they should have a resident surgeon, who would visit the wards and look after the patients daily.

BELFAST BOARD OF GUARDIANS

19 September 1865

APPOINTMENT OF ANOTHER MEDICAL OFFICER.²

Mr. Gaffikin moved that advertisements be inserted in the local papers for a properly qualified medical officer, at a salary of £40 a-year, for the union. He said that, with respect to the necessary accomplishments of the medical officer, Dr. Reid would be prepared to acquaint the Clerk as to how the advertisement should be published. He thought the scale of duties should be made public also. The salary which they offered was very small, and it was his opinion that a better qualified officer could be obtained for a higher salary. If that were the case, he would be prepared to vote for an increase of the salary.

Dr. M'Gee seconded the motion. The duties, he said, were to be learned from the Clerk; and with regard to the increase of salary, the Poor-law system did not allow them to increase it at present. It appeared to him that the salary was a small one; but, to satisfy some of the economists at the Board, he took a mean between the salaries which had been suggested by Dr. Reid—£40 or £50. He would propose that a salary of £45 be given.

² [Belfast News-letter, 1865, September 20.]

PROFESSIONAL ESTIMATE OF
PROFESSIONAL SERVICES.¹

Our experience of medical men as arbitrators for their own profession is not, we are sorry to say, to their credit, and we have a text for comment in our columns to-day worthy of attention. It is seldom that medical men are placed in a position to require their estimate of the value of professional services, and we are sorry to say it is well for their brethren that it is so, for in many instances there is no taskmaster so unreasonable, no employer so ungenerous, and no paymaster so mean and little-minded as your ex-doctor. The Cork Board of Guardians has hitherto derived peculiar lustre from its connexion with a certain retired apothecary, who from time to time refreshes his stock of public magnanimity by an attack on his medical brethren, the officers to the union, and his example has raised up competitors in the same line in Belfast. It appears that the Belfast Board of Guardians also keep a medical Cerberus whose especial role it is to snarl over every morsel which his medical subordinate gets, and, if possible, to prevent him getting anything at all. The Board want an assistant medical officer; they require the highest qualifications and unremitting labours, and they appeal to Dr. Reid and Dr. McGee to assess the value of a doctor's education and brow sweat. These gentlemen are well bestowed with this world's goods, they know not hunger, hard-work, or fatigue, and they think a medical man well and fully paid for a year's work by the sum of £45, or as one of them expressed it, "only two-thirds of what they would give a bricklayer or carpenter." The *Banner of Ulster*, in a just and well deserved condemnation of the conduct of these gentlemen, says—

"The public service, of which we speak, is a lottery, and it has always surprised us how a profession so learned, so gifted, so self-denying, so essential to public well-being as the medical profession undoubtedly is, could rest content with the "blank" in the lottery that has been awarded to it.

"The poor curates of the Established Church, miserably remunerated as they are, must give way to the medical profession. We take a case in point, one that obtrudes itself under our own note. The Belfast Board of Guardians wanted an assistant medical officer, and on Tuesday last they took the matter into consideration. The munificent salary offered was £40 a year, for a medical gentleman fully qualified, not only as a Physician, but as an Apothecary!

We are told in the report that Dr. Reid's estimate of the money value of the services of

such a gentleman ranged from £40 to £50 a year, and then Dr. McGee being desirous of conciliating 'the economists at the Board' was content to strike a mean, and propose that £45 should be given! But while he did this he added, that 'he thought the salary should be at least £1 a week, which was only two-thirds of what they would give a bricklayer, or carpenter, or any other good artisan!'

"Now, is not all this very miserable—excessively humiliating? Here we have medical gentlemen of considerable standing, and in such affluent circumstances as makes them independent of their profession as a mere income, chiming in with the wretched views of those who depreciate the medical profession. We do not blame the public at large. We believe the public as a whole, fairly value professional advice, and are willing to pay for it. But in this case what can the public do? What can the Board of Guardians do?

"They see their superlatively accomplished and eminent physician, Dr. Reid, estimating his younger brother's services at from £40 to £50 a year, as affording him ample remuneration for all the toil, study, and pecuniary outlay he has expended in acquiring his diplomas—in qualifying himself—in fact, to be installed as a fully qualified professional gentleman, and as such Dr. Reid's equal. Then comes in Dr. McGee, and he tries to mend his hand—he will strike a mean—he thinks £40 too low, while £50 will not please 'the economists at the Board'—so he fixes on £45, after the example of the sage who fixed St. Patrick's birth day.

"Now, when we find medical gentlemen, who, from their position, experience, and influence ought naturally to be looked to as the persons to uphold the honour and dignity of the profession—when we find them the first to make little of their own profession, and award it the paltriest of remuneration, how can we censure laymen if they imbibe their ideas of professional value from them? We cannot. We would be at once met by the palpable fact that the very utmost value Drs. Reid and McGee placed on the services of a properly qualified physician and apothecary for the Belfast Union was £50 a year—modified to £45!

"It is an 'ill bird that fouls its own nest,' and, we regret to say it, the medical nest has been sadly fouled by the old birds. Had the heads of the profession—the colleges with their influences—upheld the rights of the profession, instead of looking after selfish interests, there would be a different tale to be told now."

¹ [Dublin Medical Press, 1865, September 27, p310.]

We cannot look upon the course adopted by Drs. Reid and McGee with as favourable an eye as the journal we have just quoted.

We cannot believe that the ex-doctors, both of whom have occupied responsible offices in the profession, did not know the value of work to be done or of the responsibility to be incurred, and we must assume that they wished for the good opinion of cheeseparing ratepayers, who only know that they don't like to pay, and who care nothing what the object is, or how it is carried out. The good will of this class is more valuable to Dr. Reid and Dr. McGee than the approval of their professional brethren or the public approbation of honourable men, and they are welcome to the exchange.

The resolution come to by the Ulster Medical Society, which will be found in our advertising columns, shows that they have forfeited the former, and even their own colleagues cannot in their hearts accord the latter. We only wish that these gentlemen could as easily dispense with the titles which identify them with the profession as they have abandoned the *esprit de corps* which should bind them to its interests.

General Hospital
October 7th, 1865
Sixth Meeting

Present, the President, Drs. Patterson, Stewart, Whitaker, Ross.

The President shewed a fatty tumour which had been removed from the hip.

James Moore M.D.

General Hospital
November 4th
Seventh Meeting

Present, the President, Drs. Stewart, John Moore, David Moore, Whitaker, McCrea, Patterson. Dr. Ross read a paper on the fevers of Ireland.

Dr. John Moore would wish to know what opinion Dr. Ross entertained of the value of Tartaric Emetic in fever. The cases which he had observed in the ship of seaboard where he had been lately were brought from Belfast.

Dr. Ross could classify under some one of the three heads Typhus, Typhoid, and Relapsing Fever every case of fever that he had met with. He would never use Tartaric Emetic except in cases of violent delirium in strong people.

Dr. D. Moore would give large doses of Tartaric Emetic in the cases mentioned—say two grains every three hours.

The President referred to the great mortality after forty years of life.

James Moore M.D.

November 18th, 1865

Eighth Meeting

Present, the President (in the chair), Drs. Stewart, Wheeler, Patterson, H. P. Rea, D. Moore.

The President brought forward an account of 4 cases of Nævi, upon which he had operated during the last few weeks. He detailed the steps of the operation, the difficulty which he had met within one of cases and the uniformly successful results of the operation.

James Moore M.D.

469 Notice of meeting on 5th August 1865

The Ninth Meeting of the Society will be held in the General Hospital, on Saturday, the 2nd of December, at Three o'clock, P.M.

Business

The President will give an account of a case of Gun-shot Wound.

Drs. Patterson and Ross will give an account of a case of Tubercular Meningitis.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John M'Crea, M.D.
Secretary.

Belfast, 1st December, 1865.

December 2nd, 1865

Ninth Meeting

Present, the President, Drs. Stewart, Patterson, John Moore, Cuming, W. MacCormac, McCrea, Ross.

Dr. Patterson exhibited a brain which had undergone tubercular meningitis. Dr. Ross read some notes of the case.

Dr. J. Moore made some observations on the infrequency of the disease in adult life, and the suddenness with which effusion may occur.

Dr. Cuming said that a peculiarity of this case was that the granulations appeared to four or five observers to be grey. He had thought himself that there was a yellow tinge in them.

Dr. Patterson mentioned that the lips had been convulsively drawn up so as to expose the gum. This was on the same side as the squint and large tubercular deposit.

The President gave an account of case of gunshot wound of the right hand, in which amputation of the

hand had been successfully performed, and the fore-finger and thumb had been saved. Age 65 years.

James Moore M.D.

December 16th

Tenth Meeting

Present, the President, Drs. Stewart, J. Moore, W. MacCormac, McCrea.

Dr. McCrea resigned the secretaryship.

Dr. Stewart moved and Dr. MacCormac seconded that Dr. J. Moore be requested to act as Secretary pro tempore until a permanent Secretary should be appointed. The motion was carried.

James Moore M.D.

470 Notice of meeting on 13th January 1866

The Eleventh Meeting of the Society will be held in the General Hospital, on Saturday, the 13th of January, at Three o'clock, P.M.

Business

The President will give an account of a case of Gun-shot Wound.

Drs. Patterson and Ross will give an account of a case of Tubercular Meningitis.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John S. Moore, M.D.

Hon. Sec., pro. tem.

Belfast, 11th January, 1866.

13th January, 1866

Eleventh Meeting

Present, the President, Drs. Cuming, Drennan, David Moore, Nevin Moore, W. MacCormac, Patterson, Reade, John Moore and Whitaker.

It was proposed by Dr. Thomas Reade and seconded by Professor Cuming that Dr. John Moore be appointed Secretary to the Society. Carried unanimously.

Dr. Drennan exhibited the liver of a boy aged 16 years who had died from cirrhosis, and read a detailed statement of the history of the case and its treatment.

The President exhibited a leg which he had amputated some days ago, which had been crushed by a railway carriage passing over it.

Dr. David Moore presented a child 10 months old suffering from constricted anus.

James Moore M.D.

471 Notice of meeting on 27th January 1866

The Twelfth Meeting of the Society will be held in the General Hospital, on Saturday, the 27th of January, at Three o'clock, P.M.

Business

The President will bring forward a case of Amputation of part of the Hand.

The President will show a Large Tumor removed from the neighbourhood of the Parotid Gland; also, a Fatty Tumor removed from the Shoulder.

The President will show a large Tumor of the Breast.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John S. Moore, M.D.

Hon. Sec.

Belfast, 25th January, 1866.

27th January, 1866

Twelfth Meeting

Present, the President, Dr. Stewart, Dr. W. MacCormac, and Dr. John Moore

The President in absence of Dr. Browne brought forward two cases of his of amputation near the shoulder joint.

He also exhibited a fatty tumour which he had removed from a lady's shoulder and also a case of partial amputation of the hand.

February 10th, 1866

Thirteenth Meeting

Dr. Moore, President in the chair. Members present Drs. Reade, Stewart, Patterson, Whitaker, McCrea and John Moore.

The President exhibited an enormous fatty tumour which he had successfully removed from a lady's breast. It weighed several pounds. He also shewed one which he had removed from the region of the parotid gland.

472 Notice of meeting on 24th February 1866

The Fourteenth Meeting of the Society will be held in the General Hospital, on Saturday, the 24th of February, at Three o'clock, P.M.

Business.

The President will detail a case of very large Abscess of the Back.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.

Belfast, 22nd February, 1866.

Hon. Sec.

473 Notice of meeting on 10th March 1866

The Fifteenth Meeting of the Society will be held in the General Hospital, on Saturday, the 10th of March, at Three o'clock, P.M.

Business.

The President will show an extra large prepuce.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.

Hon. Sec.

Belfast, 8th March, 1866.

March 10th, 1866

Fifteenth Meeting

Dr. Moore (President in the chair), Drs. Stewart, Patterson, Smith (J. W. T.) and Whitaker.

A case of spina bifida having been introduced in which a tumour the size of an orange was placed over the lumbar vertebra, Dr. Moore (President) would be inclining to pass a double thread through the tumour though he did not think that it would be of much avail. Still it was in his opinion the only chance for the child.

Dr. Smith produced an ovarian tumour which he considered a well marked specimen of schirrhous, removed from a woman who suffered from dyspnoea and who died some 24 hours after admission to hospital from bronchitis. Some other tumours of a cystic character were also found in the abdomen.

The President shewed an elongated prepuce which he had removed and detailed the reasons which led him to remove it and the steps of the operation which was very successful.

Payment of [?'s] account was ordered.

474 Notice of meeting on 24th March 1866

The Sixteenth Meeting of the Society will be held in the General Hospital, on Saturday, the 24th of March, at Three o'clock, P.M.

Business.

Professor Cuming will bring forward notes of a case of Meningitis and show Recent Parts.

Dr. Smith will read notes of a case of Pneumo-Thorax from perforation of Pleura and exhibit Recent Parts.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.

Hon. Sec.

Belfast, 22nd March, 1866.

March 24th, 1866

Sixteenth Meeting

Present, Dr. Patterson (in the chair), Drs. Stewart, Drennan, David Moore, Rea, John Moore, and Professor Cuming.

Professor Cuming brought forward a case of meningitis and exhibited the recent parts.

475 Notice of meeting on 7th April 1866

The Seventeenth Meeting of the Society will be held in the General Hospital, on Saturday, the 7th of April, at Three o'clock, P.M.

Business.

Dr. Smith will read notes of a case of Pneumo-Thorax from perforation of Pleura and exhibit Recent Parts.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.

Hon. Sec.

Belfast, 6th April, 1866.

7th April, 1866

Seventeenth Meeting

Dr. Moore (President in the chair), Drs. Stewart, Patterson, J. W. T. Smith and Rea.

Dr. Smith exhibited the lung of a man who had died of pneumo-thorax and read history of case. No tubercle had been detected in the lung during life but hard tubercular deposits were found on post-mortem examination. The immediate cause of death was congestion of the left lung after the perforation had taken place. The perforation took place from a cavity in right lung which cavity was not detected during life.

476 Notice of meeting on 21st April 1866

The Eighteenth Meeting of the Society will be held in the General Hospital, on Saturday, the 21st of April, at Three o'clock, P.M.

Business.

Dr. Moore will bring forward a case of Amputation of the Arm.

Dr. W. Mac Cormac will give an account of some operations in which he employed Dr. Richardson's method of inducing Local Anæsthesia.

And will also give an account of a successful operation for Strangulated Inguinal Hernia occurring in a man upwards of 80 years of age.

And will exhibit the recent parts in a case of extensive Fracture of the Skull, occurring in a person formerly the subject of Fracture of the Pelvis and Laceration of the Urethra.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.
Hon. Sec.

Belfast, 19th April, 1866.

21st April, 1866

Eighteenth Meeting

Drs. Patterson (in the chair), Drennan, Stewart, William MacCormac and John Moore.

Mr. R. H. Newett was proposed by Dr. Patterson and seconded by Dr. William MacCormac and unanimously elected member of the Society.

Dr. William MacCormac read notes of several cases in which Dr. Richardson's method of inducing local anæsthesia which consists in causing a stream of ether spray to play upon the part [was used.] The first

case was that of a girl on whom an operation for onychia was performed without the slightest suffering on the part of the patient. Similar results were experienced in several other cases of the same kind. Amputation of finger and removal of part of metacarpal bone without any sensation of pain, and equally successful were two other cases of partial amputation of the hands and removal of piles etc.

Dr. MacCormac states that Dr. Richardson can only lay claim to having perfected the instrument as others had previously attempted to do so viz Dr. Hardy of Dublin. Dr. Drennan was of opinion that the anæsthetic effect of ether spray was owing to the sedative action of the medicine rather than to the cold produced, and recommended its application to other cases than operations viz neuralgia etc.

Dr. W. MacCormac gave an account of a successful operation for strangulated hernia occurring in a man upwards of 80 years of age. He also exhibited the recent parts in a case of extensive fracture of the skull occurring in a person formerly the subject of fracture of the pelvis and laceration of the urethra.

John S. Drennan M.D.

477 Notice of meeting on 5th May 1866

The Nineteenth Meeting of the Society will be held in the General Hospital, on Saturday, the 5th of May, at Three o'clock, P.M.

Business.

Election of Office-Bearers for ensuing year.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.
Hon. Sec.

Belfast, 3rd May, 1866.

May 5th, 1866

Nineteenth [Annual] Meeting

Dr. Moore (President in the chair), Drs. David Moore, McWilliam, Stewart, Patterson, Whitaker, Cuming, McCrea and Mr. Newett.

The accounts were audited by Drs. Whitaker and Patterson.

Dr. Drennan was unanimously elected President.

Drs. Ferguson and William MacCormac Vice Presidents.

Drs. Greeves and Scott Country Vice Presidents.

Drs. Stewart, Patterson, McCrea, Whitaker, Murney and H. P. Rea were elected Members of the Council.

It was moved by Dr. Patterson and seconded by Dr. Cuming and unanimously resolved that Dr. John Moore and Mr. Newett be elected Joint Secretaries for the ensuing year.

It was moved by Dr. Stewart and seconded by Dr. Whitaker that Dr. Cuming be requested to continue as Treasurer.

Dr. McCrea gave notice of his intention to propose that Dr. Manley be elected a member.

Dr. James Moore, President for the past year, delivered his address on vacating the Presidency. The address was published in the local papers.

Paper.¹ Dr. Moore then addressed the meeting before resigning the chair, when he shortly reviewed some of the more salient occurrences during his year of office, observing that at the fortnightly meetings of the Society there were always most interesting pathological specimens and cases brought forward, which underwent the fullest and freest discussion; nor could such be over-estimated in a practical point of view, and this not only to the members themselves, but especially so to the medical students who had the privilege of being present at those discussions, and so afforded the benefit of the matured skill and judgment of their seniors.

He then referred to the great value of the circulation of the several medical periodicals of the day amongst the members, which was one of the many advantages of their body, and which it was so desirable should be carried on with the strictest attention and regularity, their due circulation being, in point of fact, the back-bone, he might say, of the Society.

The subject of "increase of wages" was then touched upon. All skilled and unskilled classes in the community were now, he observed, demanding and obtaining increased remuneration for their time and skill, but the hardest worked and most expensive and responsible of all professions and callings, as theirs confessedly was, continued to be the worst remunerated as usual. But what must be considered a most serious injustice to their junior medical brethren, and also to the rate-payers themselves, was the well-known fact of tradesmen and mechanics, earning from two to three pounds a week, obtaining for their wives and families advice and medicine from the dispensaries, who were well able to pay for both. The Dispensary Medical men and Board of Guardians should resolutely set their faces against the continuance of so great an abuse as this palpably was, the time having fully come for their doing so.

The office of coroner for the Belfast district, so legitimately belonging to their profession, he stated, had since their last annual meeting become vacant, upon which a special meeting of their Society had been called by him to consider the propriety of supporting one of

their brethren to fill it, and which had been unanimously resolved upon; but subsequently it was discovered that the Town Council had in their own hands the power of appointing a Coroner for the borough of Belfast exclusively, and who had appointed a most excellent and judicious one in the person of Dr. Dill. Dr. Campbell of Lisburn, another equally deserving and well-qualified practitioner, having been elected by the Parliamentary voters for the other portion of the district, so that thus two of their body were now exercising that important office in this locality, which was a great point gained for their profession.

During the past year two of their Society, he sincerely regretted to say, had been removed by death from amongst them—Professor Ferguson and Dr. Hunter—both gentlemen in the truest sense of the term, and of highly cultivated intellects, and both deeply mourned for as men and as brethren for their always honourable and exemplary conduct and great ability as medical practitioners. He might also name Dr. Catherwood of Donaghadee, who had lately paid the last debt of nature, and who was a truly Christian and worthy man.

Two of their Society had during the year taken their leave of Belfast, and removed to practise elsewhere—he alluded to Drs. Strong and Hanna, the former to Dublin, and the latter to one of the distant colonies.

The "Royal Medical Benevolent Fund Society of Ireland" was then brought under notice, with the view of impressing the obligation which devolved upon each member of the profession of subscribing to it, so as to enable its disinterested managers to accomplish the largest amount of good possible, but which could not be done unless each and all gave that most excellent Society their countenance and best support, and of which it was so eminently deserving.

The President, after referring to some other matters of detail, concluded his very appropriate and well-received address by observing that, in relinquishing the chair he then occupied, it was with the greatest gratification he handed it over to Dr. Drennan, who not being present, he might the more freely speak of his exalted worth both as a citizen and a member of their profession, deeply learned, and of the most sterling principles; and also to make the passing remark that the new president's father, the celebrated Dr. Drennan, obtained for Belfast the title of the "Athens of Ireland" by reason of his distinguished literary attainments.

Their president, then, for the ensuing year might truly be said to be "the worthy son of a most worthy sire."

One more remark he had to make which was his being enabled to announce that during the ensuing year a large infusion of new blood might be expected into the Society, several of their younger brethren having recently intimated to him their intention of joining it.

¹ [Dublin Medical Press, 1866, May 16, p526.]

Ulster Medical Society
Session 1865-1866
President James Moore

On the motion of Dr. Cuming, Dr. Stewart took the second chair.

Dr. Cuming referred to the pleasure he had in listening to the excellent address with which they had been favoured by the outgoing President. He begged to move "That the best thanks of the meeting be given to their late President for the able and zealous manner in which he had fulfilled his official duties, and his readiness at all times to advance the Society's best interests."

Dr. Patterson had much pleasure in seconding Professor Cuming's motion. The motion was put from the Chair and carried by acclamation.

John S. Drennan, President

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

ULSTER MEDICAL SOCIETY

SESSION 1866–67

478 Notice of meeting on 2nd June 1866

The Twentieth Meeting of the Society will be held in the General Hospital, on Saturday, the 2nd of June, at Three o'clock, P.M.

Business.

A Special Report on the state of the Library.

Certain matters connected with the future interests of the Society.

Dr. Mac Cormac will give an account of a case in which Tracheotomy was performed for the removal of a pickle of Indian Corn.

Also of an amputation at the Knee Joint for a Gun-shot Wound of the Leg.

Also of an amputation of the Arm close to the Shoulder Joint. He will exhibit the parts removed in each case.

John Moore, M.D.
Hon. Sec.

Belfast, 3rd May, 1866.

June 2nd, 1866

Members present, Dr. Drennan (President in the chair), Drs. Stewart, William MacCormac, John Moore and Newett.

The President briefly expressed his thanks for the honour the Society had done him by electing him as its President.

A report from the Librarian was read pointing out the present inefficient arrangements with regard to the distribution of the periodicals, and other matters connected with the library.

Dr. Stewart moved and Dr. MacCormac seconded the following Resolution "That the President together with Drs. Cuming, Murney, Newett and John Moore be appointed a Committee to take charge of all matters connected with the management of the library and to report concerning them from time to time to the Society as they may consider necessary."

Dr. Newett brought under the notice of the Society the present state of the wax casts belonging to the Society, and suggested that they should be renovated.

Dr. Newett proposed and Dr. John Moore seconded that Dr. Manley be elected a member of the Society.

Dr. John Moore proposed and Mr. Newett seconded that Dr. Wales be elected a member.

Dr. John MacCormac proposed and Dr. Stewart seconded that Mr. H. Johnston, Surgeon, be elected a member.

John S. Drennan, President

479 Notice of meeting on 5th July 1866

President.

Dr. Drennan.

Vice-Presidents.

Dr. W. Mac Cormac.

Dr. Scott, Aughnacloy.

Dr. H. S. Ferguson.

Dr. Greaves, Cookstown.

Members of Council.

Dr. Stewart.

Dr. Whitaker.

Dr. Patterson.

Dr. Rea.

Dr. Murney.

Dr. M'Crea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore.

Mr. R. H. Newett.

The Second Meeting of the Present Session will be held in the General Hospital, on Saturday, the 7th of July, at Three o'clock, P.M.

Business

To ballot for:

Mr. T. J. Cantrell.

Dr. A. Dunlop.

Mr. H. M. Johnston.

Dr. H. C. Manley.

Dr. Angus Porter.

Dr. H. S. Purdon.

Dr. G. F. Wales.

Dr. Cuming will give an account of a case of Fibrinous Concretion of Heart, and exhibit recent parts.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 5th July, 1866.

Second Meeting

July 7th, 1866

The President in the chair. Members present, Drs. Thomas Reade, Whitaker, Patterson, H. P. Rea, John Moore, MacCormac, Murney, Dr. Nevin Moore, Stewart, Professor Cuming, McCrea, Messrs. Gribbin and Newett.

The following gentleman were elected members, Mr. T. J. Cantrell, Dr. Dunlop, Holywood, Mr. H. M. Johnston, Dr. H. C. Manley, Dr. Angus Porter, Dr. H. S. Purdon, Dr. Wales.

It was moved by Dr. Patterson and seconded, that the Council should take immediate steps regarding the furniture in the new rooms.

Report from Council was read stating that the hours of attendance of the Librarian were from

10a.m. till 1p.m. and recommending that the books be still kept in the present library, and that the periodicals be placed on the table in the new rooms for a month after their issue.

Dr. Thompson of Bangor was proposed by Dr. Cuming and seconded by Dr. Whitaker.

Dr. McDonnell was proposed by Dr. W. MacCormac and seconded by Dr. D. N. Moore.

John S. Drennan

480 Notice of meeting on 4th August 1866

President.

Dr. Drennan.

Ex-President.

Dr. James Moore.

Vice-Presidents.

Dr. H. S. Ferguson.

Dr. Scott, Aughnacloy.

Dr. W. MacCormac.

Dr. Graves, Cookstown.

Members of Council.

Dr. Stewart.

Dr. Whitaker.

Dr. Patterson.

Dr. Murney.

Dr. M'Crea.

Dr. Rea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore.

Mr. R. H. Newett.

The Third Meeting of the Present Session will be held in the General Hospital, on Saturday, the 4th of August, at Three o'clock, P.M.

Member to be Proposed:

Alexander H. H. M'Murtry, M.D., Q.U.I., Belfast.

Members to be Ballotted for:

Henry Thomson, M.R.C.S. Eng., Bangor.

Dr. McDonnell, Belfast.

Morbid Specimens.

Dr. Cuming will exhibit specimen of Fibrinous Concretion of Heart.

Dr. Cuming will read case of Pericarditis, with unusual Cerebral Symptoms, and exhibit recent parts.

Case to be Read.

Dr. J. W. T. Smith will read notes of case of unusual local Spasmodic Affection.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore, R. H. Newett,
Secs.

Belfast, 2nd August, 1866.

Third Meeting

August 4, 1866

Present, the President in the chair, Professors Reade and Cuming, Drs. Patterson, McWilliam, Manley, Messrs. Thompson, Cantrell and Newett, Dr. John Moore.

Dr. Alexander H. H. McMurtry was proposed by Dr. Cuming.

Dr. Henry Thompson, Bangor, was elected unanimously.

Dr. Cuming exhibited a specimen of fibrinous concretion of the heart, and read a paper on a case of pericarditis with unusual cerebral symptoms and exhibited the recent parts.

John S. Drennan

481 Notice of meeting on 1st September 1866

The Fourth Meeting of the Present Session will be held in the General Hospital, on Saturday, the 1st of September, at Three o'clock, P.M.

Members to be Proposed:

Henry Talbot Higginson, M.D., Edin., Lisburn.

Henry Brown, L.R.C.P., & L.R.C.S, Edin., Belfast.

Alexander H. H. M'Murtry, M.D., Q.U.I., Belfast.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 2nd August, 1866.

Fourth Meeting

September 1, 1866

Present, the President in the chair, Drs. MacCormac, Whitaker, Thompson Bangor, and Mr. Newett.

Dr. H. H. McMurtry was unanimously elected a member of the Society.

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

The Secretary was directed to publish in the next notice-sheet, that the meeting of the Society would, for the first time, be held in the new rooms in the Charters Wing of the hospital, and to request a large attendance of the members.

Dr. Whitaker proposed and Mr. Newett seconded that Henry Brown Esquire L.R.C.P. and L.R.C.S. Edinburgh be elected a member of the Society.

Dr. MacCormac proposed and Dr. Thompson seconded that Dr. Henry Talbot Higginson of Lisburn be elected a member of the Society.

John S. Drennan

482 Notice of meeting on 6th October 1866
The Fifth Meeting of the Present Session will be held in the General Hospital, on Saturday, the 6th of October, at Three o'clock, P.M.

Business.

Member to be Proposed:

Josias W. Patrick, L.R.C.P., & L.R.C.S. Edin., Carrickfergus.

Members to be Ballotted for:

Henry Talbot Higginson, M.D., Edin., Lisburn.

Henry Brown, L.R.C.P., & L.R.C.S. Edin., Belfast.

Papers to be Read.

Dr. J. W. T. Smith will read notes of a case in which there was a peculiar Spasmodic Affection.

Dr. Seaton Reid will read a paper on the recent Cholera cases in Belfast.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 4th October, 1866.

Fifth Meeting

October 6, 1866

Present, the President in the chair, Drs. Whitaker, Patterson, Dill, McMurtry, John Moore, Professors Reid and Cuming, Drs. McWilliam, H. P. Rea, Brice Smyth, S. H. [sic] Purdon, and Messrs. Johnston and Newett.

Henry Talbot Higginson M.D. Edinburgh and Henry Brown L.R.C.P. and L.R.C.S. Edinburgh were un-animously elected members.

Dr. Cuming proposed and Mr. Newett seconded Josias Wilson Patrick L.R.C.P. and L.R.C.S. Edinburgh for membership.

Dr. Reid read his paper on the recent cholera cases in Belfast:

Paper:¹ Mr. President and Gentlemen,—You are aware that several medical men have agreed with me in stating that cases of Asiatic cholera had been seen by us in Belfast, and I have thought my placing before you some information regarding these cases might be interesting, the more especially as one of them had struggled successfully against the disease in my hospital, and thus afforded an opportunity of noting particularly the course of his disease. I shall notice the cases in the order of their occurrence, premising that the three first cases resided very near each other, but that no intercourse could be traced:—

Case 1.—On the morning of the 10th of August I was requested by Dr. Murray, of Ballymacarrett, to see a dispensary patient, called Thomas O'Neill, aged 45, who had left Huddersfield on the 6th, in which town another Irish labourer, called Heard, died of cholera on the 12th. O'Neill spent the greater part of the 6th in Liverpool, where cholera was epidemic, arrived in Belfast on the 7th, but made no complaint of illness till diarrhœa set in at right p.m. of the 9th, followed by vomiting at two a.m. of the 10th, and by cramps at four. I saw him at nine; his eyes were sunken; the pupils half dilated, with a dark areola around the lids; his tongue cold, and voice husky and feeble; the hands were cold, blue, dry and shrivelled, as were also his feet; his pulse was barely perceptible, and the respirations hurried and noisy. The evacuations had all been thrown out.

We saw him again about one in the afternoon. He was then pulseless, less sensible, colder, and more livid, unable to open his mouth perfectly; there had been no more vomiting or purging, and the catheter found no urine. He died at two, about eighteen hours after he took ill.

The body was interred immediately, the house whitewashed, and the clothing destroyed.

Case 2.—On the morning of the 12th, Dr. Murray asked me to see Edward McGowan, aged 40, living in Keenan's-court, a few yards from the house near Quinn's-entry, in which O'Neill had died. This man was attacked with diarrhœa at ten p.m. on the 11th of August, followed by vomiting at two a.m. of the 12th, and by cramps at four, and Dr. Murray found him in a state of collapse at five. I saw him between seven and eight o'clock, when he was very blue, cold and pulseless, and he died about nine. All the evacuations had been thrown away in this case also.

¹ [Medical Press and Circular, 1866, October 31, p432.]

Case 3 When Dr. Murray was returning from McGowan's he was asked to see James McGowan, aged 27, living in No. 71, Short Strand-street, and believing him to be ill with cholera, requested future evacuations to be preserved. It happened that when I was looking for Edward McGowan's residence, I was taken to James' house, who was not related to Edward. James' bowels had acted at nine a.m. and four p.m. of the 11th, and he felt nauseated in the afternoon. He had taken during the day only one glass of whisky. He went to bed at nine, began to vomit about one a.m. of the 12th, and diarrhœa set in at once with profuse and very frequent evacuations. No urine was passed after three o'clock, and the cramps set in about eight. Through Dr. Murray's foresight, I was enabled to see an evacuation, which was almost colourless and distinctly "rice-water" in appearance. He consented to enter the cholera ward of my hospital, and was removed there in the recumbent posture about nine o'clock.

On admission his pulse was 120 and feeble; his nose and tongue were cold; his voice husky and feeble, and his hands, limbs, and scrotum livid and cold; his eyes sunken and surrounded by a dark areola, and his pupils half dilated.

He was placed in a warm bath for twenty minutes at 103 F., which gave him great relief, and was well rubbed with hot towels on leaving it; then clothed in a long flannel shirt, and had his arms enclosed in long ribbed woollen gauntlets, vessels of hot water placed in his bed, and large sinapisms applied along the entire spine and over his epigastrium. He expressed himself often as being greatly relieved by the warm bath, which also improved the temperature of his body and tongue, and gave volume to his pulse.

He got at once ten grains of calomel and three of opium, and was directed to take ten grains of calomel every hour for four doses.

Positive orders were given that in addition to the calomel, he was to be allowed to take nothing into his stomach except a tablespoonful of water every half hour, because I had so repeatedly found such directions beneficial in allaying the vomiting of English cholera, and of the Relapsing Synocha fever, that I invariably endeavour to enforce them when treating Asiatic cholera.

My wishes were most efficiently carried out by my assistants, Drs. Farelle and Lindsay, and the patient willingly co-operated.

No vomiting took place till four in the afternoon, so that the medicine had remained on an absorbing surface for seven hours.

A report of his condition was taken every two hours during the day and night by my very intelligent assistants. I shall not trespass on your time by reading them in detail, but confine myself to placing before you a condensed summary of them as entered by myself in my morning and evening reports:—

I learned at nine in the evening that he had vomited a greenish fluid repeatedly between four and six o'clock, that at the latter hour his pulse was barely perceptible, and his hands cold and livid. These symptoms of increased collapse appeared to have been benefited by the use of small quantities of hot whisky punch, for I found his pulse 126, and of fair strength, his nose, tongue, feet, and hands warm and dry. The bowels had not acted since admission; he had passed no urine, and the catheter found none. He complained much of thirst and of his continued restlessness, and had suffered much from cramps.

He had now taken six of the ten-grain doses of calomel. He was directed to take ten grains every two hours for two doses, and then every four hours; to have large sinapisms over the epigastrium and the entire length of the spine, and to take half an ounce of whisky in an ounce of milk every two hours, and if restless at one in the morning, to get two grains of opium.

At nine in the morning of the 13th his pulse was 126, feeble; his tongue, nose, and body warm and dry; his lower gums were coming under the influence of the mercury; he had vomited ten times during the previous twelve hours; had passed no urine, nor had his bowels acted.

The calomel powders were continued every four hours, and a drachm of blue ointment rubbed every four hours into each arm-pit, and iced whey given in small quantities as a drink.

At noon the bowels had acted three times, and there was bile in the evacuations. At six in the evening his pulse was weaker: his hands and feet cold and livid; he had vomited repeatedly a bright green fluid of acid reaction, and he was very listless and tossing much about.

At nine in the evening his pulse was 122, and feebler than in the morning; the bowels had not acted since noon; he had passed no urine, and the catheter again got none.

A blister was applied over the epigastrium, and he got some calcined magnesia in mint water; the inunction was continued, and a drachm of blue ointment, rubbed up with two ounces of olive oil, was injected into the rectum. The calomel, of which he had now taken 120 grains, was discontinued.

On the morning of the 14th his pulse was 114, feeble; and his hands, feet, and body colder, although his tongue and face were warmer; the bowels had not acted again, nor had he passed any urine; he had vomited a yellow fluid eight or ten times during the night; he was more drowsy, though still intelligent; his gums more under the influence of mercury, and his voice still choleraic.

At noon I found his pulse fuller and stronger, and his colour improved; he had only vomited twice; the bowels had not acted, nor had he passed any urine, although asked to do so. Every precaution had been

taken to obtain any that passed when the bowels were acting, or at other times.

Believing that reaction had now really set in and that everything depended on a restoration of the urinary secretion, he was directed to take two drachms of the very efficient diuretic mixture of the hospital every half hour in iced whey, and to have a large sinapism over his loins. I need not say how gratified we all were to find at nine in the evening that after a suppression of the secretion of urine for eighty-four hours, he had passed one ounce about an hour before, having then used about eight ounces of the diuretic mixture. The urine was coagulable by heat and nitric acid, and became a dark or purplish colour on the addition of the acid. Professor Parkes states that this peculiar pigimentary discoloration on the addition of acids, the nature of which is not yet decided, is present with the first urine passed in all cases of Asiatic cholera, and that, in fact, it is the best diagnostic mark of the existence of the disease in doubtful cases.

His bowels had acted twice; he had vomited a yellow fluid five times; his pulse was 110, and feeble.

The inunction was continued, and the mercurial enema repeated; a large sinapism kept on the loins till the skin was returned, and the body well rubbed with dry cloths every two hours.

On the morning of the 15th the pulse had fallen to 80, and was full and strong, and the temperature everywhere good; the respirations were now counted for the first time, and found to be 14; he had vomited eleven times, and had hiccup for several hours. The mercurial enema was returned without any fæces, and he was unable to pass any urine.

A pint of tepid water was thrown into the rectum, where it remained for half an hour, and then passed off with fully a pint more of semi-fluid bilious matter, but unaccompanied with any urine.

At nine in the evening his pulse and respirations were the same, and his temperature everywhere good; he had slept much during the day and was very drowsy; he had vomited eight times, but retained several spoonfuls of bread and milk; the bowels had acted twice, and at half-past five he passed two ounces of urine of a sp. gr. of 1.015, acid, and slightly coagulable.

In the hope of re-establishing thoroughly the renal secretions, four ounces of whisky and eight ounces of the diuretic mixture were directed to be taken during the next twelve hours in a quart of iced whey, and some lemon juice given after his magnesia mixture, in the hope of checking the vomiting.

On the morning of the 16th his pulse was 84, full and strong, and the respirations 16; his tongue dry, his gums sorer; he had vomited nine times; taken his diuretic mixture, and retained a fair amount of his bread and milk; he had passed 13 oz. of urine during the night, neutral in its reaction, and of sp. gr. 1.014, slightly coagulable, and foetid when heated. The bowels

had acted twice, evacuations viscid bile and some blood. Being still much oppressed, a blister ten by four was applied to the nape of the neck for four hours, and followed by a hot poultice.

At nine in the evening his pulse was 88, and respirations 16; the bowels had acted three times, first evacuation pure blood, the second composed of bile and blood, and the third less bloody. He had secreted seven oz. of urine, which was alkaline, sp. gr. 1.015, and with a trace of albumen. Believing that the blood indicated a congested condition of the intestinal tract, he was directed to take half an ounce of castor oil during the night.

On the morning of the 17th his pulse was 90, and respirations 18; the evacuations from the bowels were bloody and scanty, but he had passed 30 oz. of urine during the night, which was alkaline, sp. gr. 1.015, and free from albumen, but fearfully foetid on being heated. On this day the vomiting ceased and did not return, and the evacuations from the bowels ceased to be bloody.

On the 18th I found that, notwithstanding the secretion of 63 oz. of urine during the previous twenty-four hours, his pulse was only 86, and his respirations barely 16. He had passed one yellow evacuation free from blood, and complained of being drowsy; his pupils were dilated and there was some muttering delirium.

A blister was applied over the forehead, and he was directed to take twelve forced inspirations every half hour, with the object of dilating the lungs to their fullest extent, and thereby purifying the blood. I decided also on establishing a freer secretion from the intestinal surface by the daily administration of castor oil.

On the 19th his pulse was 88, his respirations 16. The bowels had acted five times, without any blood, and he secreted 105 oz. of urine during the previous twenty-four hours, acid, of sp. gr. 1.010, and not coagulable. He was more sensible; his memory improved, and he was free from delirium; his tongue moister and cleaner. The blister rose well, and Professor Cuming very kindly ascertained for me that the serum of the blistered surface contained a larger proportion of urea than recent experiments have shown to be always present in the blood. The forced inspirations, castor oil, and diuretic mixture were continued, and he had fowl broth, with a large amount of parsley in it.

On the 20th his pulse was 86; the respirations 18; the bowels had acted five times, evacuations fluid and bilious; he had passed 95 oz. of urine in twenty-four hours, acid, and of sp. gr. 1.010, and faintly coagulable; but his tongue had again become dry, and there was some delirium. In addition to the other treatment he was now directed to take 2 oz. of green tea during the next twenty-four hours, infused in a quart of water.

On the 21st his pulse was 80, and the respirations 18; the bowels had acted five times, and the evacuations were very yellow; he had passed 111 oz. of urine

during twenty-four hours, sp. gr. 1.014, acid. There was no delirium; he felt better, and his intelligence was improved. His castor oil, green tea, diuretic mixture, and forced inspirations, were continued.

On the 22nd the pulse was 84, the respirations 19; the bowels had acted four times; he had passed 120 oz. of urine during the previous twenty-four hours, acid, and sp. gr. 1.010. Same treatment continued.

On the 23rd his pulse was 89, respirations 16; bowels had acted four times; the urine amounted to 102½ oz., acid, sp. gr. 1.013; his intelligence had improved much, and his tongue was clean and moist all over. No change in treatment, except that he was allowed to leave bed.

On the 24th his pulse and respirations were about the same; his bowels had acted six times, and he had passed 126 oz. of urine, and was declared convalescent.

Case 4.—This patient was a female, called Sinclair, aged 38, who was admitted into hospital from Hudson's-entry, at seven p.m. of the 17th August. She stated that she had been attacked with diarrhœa at five A.M. of the 15th, followed by vomiting at nine, and that cramps were associated with these symptoms on the forenoon of the 17th. She had been seen by the dispensary medical officer, Dr. Rea, about two, who directed her removal to hospital. On arrival she said that her bowels had been very loose during the day till about five o'clock, that she had vomited four times, and had the toes separated from each other by the cramps. She was pulseless at the wrists, her tongue was cold, her nose cold and livid, and her voice feeble. Her eyes were sunken and surrounded by a dark areola, and the pupils rather dilated.

She was placed in a warm bath, which for a time improved the heat of the body, and made her tongue warm. On leaving the bath she got ten grains of calomel and three of opium; had sinapisms applied along the entire spine and over the epigastrium, and was clothed in a long flannel chemise, and ribbed woollen gauntlets over her arms, dry friction applied to the extremities, and pans filled with hot water placed in her bed.

At nine p.m. she was still pulseless; the hands, arms, body, and feet were warmer, but the face, the nose, the tongue, and the breath were cold; she had retained three ten-grain doses of calomel, the two last of course without opium; she had not vomited, nor had the bowels acted. Ten grains of calomel were directed to be given every four hours, and a teaspoonful of whisky with a tablespoonful of iced whey every half hour.

At eleven p.m. she passed a scanty evacuation, of the consistency of gruel and a pale drab colour, but no urine.

On the 18th she remained pulseless, with her hands cold, livid, shrunken, and sodden, and her feet warm. Her tongue and breath were cold; she had neither vomited nor passed urine since admission, nor did the catheter get any; the pupils were rather contracted; her

intelligence perfect; the areola continued around the eyelids, and she had suffered severely from cramps in her legs during the night. The treatment was continued.

At noon she was still pulseless, but less intelligent; she had a slight convulsion before her death, which took place about four. This patient was seen in the hospital by Drs. Murney and Johnstone, who agreed with me that it was a case of Asiatic cholera.

Case 5.—I was requested by Dr. Porter to visit one of his dispensary patients about noon on the 11th of September, whom he believed to be suffering under Asiatic cholera. He lived at No. 6, Bow-street, Belfast, was called Patrick Wilson, and aged 50. I learned from the very accurate and minute notes taken by Dr. Porter, that he had been attacked with diarrhœa at two in the morning, followed by vomiting at eight, and soon afterwards by cramps. When I saw him his voice was husky and feeble; his tongue and breath cold; pulse barely perceptible, and his eyes sunken, with a dark areola around the lids; his hands were cold, blue, and shrivelled, and the cramps very severe.

I had no hesitation in agreeing with Drs. Porter and Henry Johnstone that this man was suffering under Asiatic cholera. I recommended his removal to hospital, as he was lying on straw in the corner of a room in which there was no fire. He consented to go; but when his friends saw the kind of conveyance sent to remove him in, they would not allow him to enter it.

Dr. Porter attended to him most sedulously, and did everything in his power to promote his recovery. Various attempts at rallying took place, but in the evening he was found pulseless, colder and more livid, and less sensible; and he died about one in the morning of the 12th, twenty-three hours after he took ill. At one of Dr. Porter's visits he saw a distinct "rice-water" evacuation. He passed no urine after eleven a.m. of the 11th. Nine hours after death Dr. Porter found his hands, wrists, and face of a bluish colour: his ankles and parts of his legs purple, with some blue spots on his toes, and his chest still warm.

Case 6.—Since the foregoing histories were read before the Medical Society, a woman called Rose M'Cullough, aged 40, was admitted to hospital at 7 p.m. of the 9th October; she had been drinking for several days before the 5th, when diarrhœa and vomiting commenced. On admission her skin was cold, as also her tongue, eyes sunken, with a dark areola, pulse 126. She stated that she had felt pains in the calves of her legs and hands; but as she did not call them cramps, and the symptoms being less intense than in other cases, I did not pronounce her at first to have Asiatic cholera, and after giving her a warm bath, I administered the medicines used in Case 3, but less frequently. The bowels had become quiet, but the vomiting was very frequent.

The catheter obtained half a drachm of urine, which on being examined on the morning of the 10th was found to be acid, not coagulable, but gave with heat and

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

nitric acid a distinct brownish colour. This discoloration alarmed me, as Parkes' opinion of its diagnostic value, already quoted, had been supported by Case 3.

I shall not detail the reports taken every two hours, but limit my notice of this case to stating that the symptoms became gradually more intense, till she died in unmistakable collapse at one o'clock of the 11th. Rigor mortis occurred in fifty minutes. The vomiting had continued most distressing. The bowels acted only three times after admission, and then scantily. The secretion of urine was also very scanty, the catheter never obtaining more than three drachms, which was found coagulable on every occasion but the first, acid in its reactions, and gave always a dark or purplish discoloration with nitric acid and heat.

I am so impressed with the importance of this discoloration of the urine, that I trespass on your space with a very brief notice of some other cases, which corroborate the opinions of Professor Parkes and Dr. Warburton Begbie of its diagnostic value.

Case 7.—A boy called Peter Carty, aged 8, was admitted into my hospital at midnight of the 14th October, from the same locality in which McCullough had lived, but no intercourse was traced. I saw him about an hour after admission, and found him pulseless, cold, livid, and with all the symptoms of collapse, after sixteen hours' vomiting, diarrhœa, and cramps. The catheter got no urine till about noon of the 15th, when a few drops were obtained, which being placed on white paper was found acid, and gave a distinct purple colour with nitric acid. He passed into the stage of consecutive fever. The urine was tested on every occasion it was obtained by the catheter, or passed by himself, and was invariably found coagulable and giving discolorations varying from pink to dark purple. The urinary secretion was restored to the extent of eight ounces daily, and a profuse discharge also of bile; still he became gradually less sensible and died.

Anne Downey, aged 54, who had suffered from renal dropsy, was sent into hospital in consequence of having had vomiting and diarrhœa for two days, without cramps, but with great failure of the heart's action; ultimately becoming pulseless and cold, death taking place twenty-nine hours after admission.

Dr. Warburton Begbie, in his paper in the *Edinburgh Journal of Medicine* for November, 1849, states, "that he had examined the urine in cases of diarrhœa, and so-called choleroïd diarrhœa, and had never found albumen, epithelium, and bile in such cases," bile being at that time considered to be the cause of this discoloration of the urine.

In Downey's case her urine was examined, and found acid, albuminous; but no discoloration followed the tests applied in the other cases. This case was not returned as one of Asiatic cholera, as I believe that renal disease was the cause of her death. Rigor mortis had not commenced at the end of two hours.

[After] which an interesting discussion followed.

John S. Drennan

483 Notice of meeting on 3rd November 1866

President.

Dr. Drennan.

Ex-President.

Dr. James Moore.

Vice-Presidents.

Dr. H. S. Ferguson.

Dr. Scott, Aghnacloy.

Dr. W. Mac Cormac.

Dr. Graves, Cookstown.

Members of Council.

Dr. Stewart.

Dr. Whitaker.

Dr. Patterson.

Dr. Murney.

Dr. M'Crea.

Dr. Rea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore.

Mr. R. H. Newett.

The Sixth Meeting of the Present Session will be held in the General Hospital, on Saturday, the 3rd of November, at Three o'clock, P.M.

Business.

Member to be Ballotted for:

Josias W. Patrick, L.R.C.P., & L.R.C.S, Edin., Carrickfergus.

The President's Address, it being the commencement of the Winter Session.

To make arrangements for the Annual Dinner.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 1st November, 1866.

November 3rd 1866

Present, the President in the chair, Drs. Pirrie, James Moore, A. Dunlop, Cuming, Patterson, Browne, Thomas Reade, McCrea, B. Smith, John Moore, J. S. Reid, H. P. Rea, McWilliam, Wales, Whitaker, Stewart, MacCormac, Surgeons Gribbin, McCleery, Johnson and Newett.

Josiah Wilson Patrick L.R.C.P.E. and L.R.C.S.E. was unanimously elected a member.

The President read his address which was listened to with attention and elicited the applause of the Society.

Paper:¹ Gentlemen,—In conformity with a custom which has been generally, if not invariably observed, I proceed to address to you a few remarks at the commencement of our Winter Session. Whilst by no means affecting originality, or aspiring to the dignity of an Inaugural Discourse, these may serve to direct the attention of our more recently elected members to the principal objects of this Society, and the best means of effecting them.

I have already taken the earliest opportunity of expressing my sense of obligation for the honour of being appointed your President for the current year, and I need now merely repeat that it was an honour quite unsolicited on my part, but only the more prized for its being spontaneously bestowed. I should have sincerely rejoiced if some more distinguished member of the profession had been at this time selected for the office—not only for the increased dignity to have been thereby reflected upon it, but for the substantial benefits which talent and influence installed in this chair might have conferred on our Association at a somewhat critical period of its existence.

You are aware, gentlemen, that this society, judging from the decrease in the number of its subscribers and the diminished attendance at its meetings, has fallen off somewhat of late from the position it formerly held, and which, from its designation as the “Ulster Medical,” it would even seem called on to assume. On the causes of this declension I shall not enter, if for no other reason than because I am really very imperfectly informed as to their nature and extent. Amongst them, undoubtedly, cannot be reckoned any want of ability or energy on the part of my predecessors in this chair, or the other official members of the Society. Nor can I for a moment suppose that there has been, at any time, a lack of inclination amongst the practitioners of this locality to maintain an institution so capable of diffusing professional information, and advancing their own claims to confidence and respect.

Let us conclude then that our society has been merely suffering of late from a little temporary “Asthenia”, indicative of no serious organic disease or senile debility, and easily removable by some simple measures for imparting additional warmth to its members and increasing the force of its cerebral circulation. The copious supply of new blood infused into it during the present year will doubtless contribute much to its convalescence, whilst we have already had proof, in the proceedings of our Summer Session, that there is no decline whatever in the vitality of the old.

Amongst those who formerly co-operated with us, we have to lament the recent death of a respected associate in the person of Dr. Halliday. He died comparatively young, and the arduous duties of Dispensary Medical Attendant, which he so sedulously discharged, and which had latterly pressed very heavily upon his strength and spirits, hastened in all probability his passage to the grave. He filled for several years the office of Treasurer to the Clinico-Pathological Society, and took a frequent part in its discussions, and those of the older “Medical.” In token of respect for his memory the members of this Society attended his funeral, and his professional and personal worth was still more vividly attested by the thronging together of his poorer friends, as the earthly remains of their kind “District Doctor” were carried to the tomb.

With the exception of this loss on our part, and some others less recent, we meet here to-day under circumstances specially propitious. The room, which by the kindness of the Hospital Committee, had been for many years devoted to our exclusive use, has been of late partially applied to other purposes. For this restriction, however, we have received in the convenient and capacious apartments in which we this day assemble for the first time a much more than equivalent return. In them we possess not only a large, well lighted, and commodious place of meeting and reading-room, but space sufficient for the suitable arrangement of our collection of pathological portraits, casts, and specimens. Whether it may be advisable hereafter to transfer our library also hither must depend on circumstances, and will be a question for future consideration. The Society must feel truly grateful, and will, I presume, express its acknowledgements to those to whom we are indebted for this very valuable endowment. To Mr. Charters, the munificent donor of this wing of the hospital, to the Hospital Committee, who have conceded this portion of it to our use, and to our worthy Vice-President, Dr. William MacCormac, at whose suggestion and by whose intercession it was mainly obtained—to each and all of these we are certainly deeply indebted, and owe the expression of our warmest thanks.

Among the other valuable results of this seasonable acquisition, we have now that portion of our revenue, recently expended on the rent of hired rooms, at our disposal for other purposes. Of these there is surely none more eligible, none more urgent, than the improvement of our defective library, by the addition to it of books of sterling professional value. One of the primary objects of the Society, as stated in its fundamental rules, is “to afford its members increased facilities of consulting the best medical works and periodicals,” but in consequence of restricted resources, that object has been of late very imperfectly accomplished. A substitute for the purchase of new works was attempted by the hiring of them from a lending library. But however a means of this kind may answer as a supplement

¹ [Dublin Medical Press, 1866, November 22, p528.]

tary one, or for the procuring of publications of comparatively trivial interest and the lighter literature of the day, it affords very inadequate facilities for the serious study of elaborate treatises, and none whatever for the consulting of voluminous and systematic works. For such purposes a permanent and progressive library is absolutely necessary, and most of us can only hope to enjoy such a possession by holding it in common. At no time more than the present has there been required on the part of every member of our profession, who wishes to promote its advancement or uphold his own credit, an acquaintance with its scientific history and actual progress. The spirit of free inquiry, that motive spirit of the age, is acting in no field more energetically than that of medicine. Deny or deprecate the fact as we may, medical theory and medical practice, too, are at present in a state of transition. No doctrine, however venerable, no statement, however often attested, but must submit now to fresh scrutiny, and to the confirming, destroying, or emendatory hand of the strictest criticism, armed with new instruments of research. The number of able and ardent inquirers in every department of our art was never before so great, and the press teems with the results of their investigations. He who ignores these results, who in the midst of all this sifting of old opinions and seeking for new truths, rests satisfied with the traditionary formulas of medical faith, will soon find he is behind the time, and has forfeited his claims to consideration even as a "practical man." His shallow dogmatism may impose upon others yet more ignorant than himself, but he will be held in no esteem by the only real judges—the well-instructed members of his own profession. I say, then, that were this Society merely an economical instrument for communicating through books and periodicals the accessions to medical knowledge that are continually being made, and the course of the ever-flowing currents of medical philosophy, it would be amply deserving of our support. We have here a comfortable reading-room open at convenient hours; we have secured the services of a competent librarian, at hand most of the day for the receiving and giving out of books; a complete catalogue has been lately drawn up, and a more satisfactory mode of circulating the journals adopted. In short, for the formation and maintenance of a useful and creditable medical library, we want nothing now but sufficient funds and their judicious expenditure.

But this Society was not intended to be merely a Book-Club. It has important objects besides that of furnishing us with other men's opinions, however valuable these may be. It is meant for the expression, discussion, and diffusion of our own. The comparatively short period of time to which our meetings are limited is an obstacle to the introduction of theoretical questions requiring lengthened exposition or prolonged argument, but has been found quite sufficient for the reporting of interesting cases, for the exhibition of patholo-

gical specimens, and for instructive commentaries on both.

Medical experience is constantly presenting, if not absolutely new subjects for notice, though such not unfrequently occur, at least novel relations of, and inferences from, the old. Every busy practitioner meets with striking and suggestive cases, with points in pathology, or with results of treatment worthy of record and subsequent reflection. To determine the true worth and bearing of such incidental facts nothing can more effectually contribute than the submitting of them to minds of kindred pursuits, whilst at the same time free from the bias which so often unconsciously attaches to the original observer. "Truth, like a torch, the more it's shook it shines." Its flame gathers strength, and its light flashes farther for the motion, whilst in its swift passage from mind to mind it throws off the adventitious particles which at first obscured its lustre, and becomes at length a pure effulgence—a lumen siccum never afterwards to be extinguished.

An acute, though unpremeditated question, an apt analogy or a pertinent counter-instance, may often aid effectually in defining a dubious fact or dissipating a nebulous hypothesis. Nor is the utility of our discussions to be measured by their more immediate or obvious results, or the length to which they are carried. Short suggestions may be thrown out in the course of them to be afterwards worked upon and tested, tacit assumptions may be quietly corrected, or a new importance suddenly imparted to some half-forgotten observation or train of thought. In a word, the simultaneous action of different minds on the same subject is often the shortest, simplest, and most decisive means of ascertaining its real import and value. As a criterion it operates "tuto et cito," and here, at least, we will anticipate always also "jucundé." The differences and the concurrence of the inquirers alike aid in the discovery and development of truth. The one stimulates the desire, the other strengthens the capacity for attaining it, whilst the very seeking of it in common augments the sense of its importance. On disputed points of theory or practice, a society like ours has, of course, no pretensions to be considered an ultimate tribunal. As a court of opinion, however, we may sometimes properly assume the functions of a grand jury, and quash the bills submitted to our scrutiny, or remit for further trial. Perhaps an occasional interchange of single papers or collected transactions between ourselves and other kindred societies might prove conducive to the common objects of both.

On questions of professional etiquette and personal difference—should such unfortunately occur—our council might, I think, advantageously continue to occupy the place filled by that of a former society, and act as a court medical for their amicable arrangement. All who have the dignity of the profession at heart would certainly prefer a reference to some such friendly arbitra-

tion to exposing their personal grievances or dissensions before an indifferent public. On this subject, I may observe that the code of medical ethics drawn up by the Belfast Medical Society is still extant, and worthy, I think, of adoption by our own.

In the relations of our profession with the public at large such a Society as this might, it appears to me, render material service to both parties, and occupy a higher position than ours has yet held. Whilst, gentlemen, no other body of citizens, I assert, confer such an amount of public benefit in so liberal and self-denying a spirit, we medical men are undoubtedly deficient in some of the chief elements of popular consideration. Very few of us are affluent—most of us of comparatively small means, and this “*res angusta*” must tend to impair the social estimation in which we are held, especially in a community where wealth is not only the general object of exertion, but too apt to be esteemed its highest reward and the prime standard of value. Nor can we boast of imposing titles, or corporate political influence. In short, we want all the coarser elements of power, and it is therefore not surprising if we be sometimes treated as the weak. Now, the mere associating of ourselves together, be it only for scientific objects, must strengthen at least our moral claims to consideration by exalting our character as a class. But it may do more than this: By cultivating among ourselves a certain laudable “*esprit de corps*,” and common methods of action, it will enable us, on the good old principle of “*vis unita fortior*,” more effectually to maintain our professional status and defend our professional rights, should either become the object of depreciation or attack.

I by no means wish to convert the Society into a trades’ union for the maintenance or advance of wages—though trades’ unions themselves have their strong points of justification. I would not even desire much of our time to be spent in discussions on the subject of fees. But even here, inasmuch as we are all, I presume, quite willing, individually, to accept such offerings, it might not, I think, be anywise inconsistent with professional delicacy if, as a united body, we should come to some understanding as to their suitable amount. There is an unpleasant ambiguity about that polite Latin word, “*Honorarium*,” and an occasional disagreeably close translation of it by our patients, which an authoritative definition of the term by ourselves might help to amend. Our junior brethren at least might find it not unfrequently desirable to be able to refer for an ample meaning to a recognised medical dictionary.

On matters of public hygiene and medical police, this Society might, I conceive, sometimes originate valuable suggestions, or at least offer valuable advice when consulted by our municipal or other local authorities. As a sort of standing counsel on such questions, its services if required would, I am sure, be always gladly rendered. That there is no indisposition to allow its due weight to professional opinion on matters regarded as

within its province, I may refer to a late occasion where an important point in the administration of the adjacent hospital was mainly determined by an appeal to medical authority.

It is quite true that on some subjects in sanitary science—as, for instance, the preventive and curative management of the formidable epidemic now within our boundaries—we may fail to be unanimous, and our deliberations may thence yield in their result but an uncertain sound. But we should not, in my opinion, fear to let such discordance be known. “*Doctors differ*,” no doubt; it is only theologians and lawyers who always agree—but we seldom differ for difference sake, but simply because the subjects on which we are called on to pronounce are often of a kind in which positive knowledge is at present unattainable. On such matters difference of opinion amongst “*experts*” implies serious grounds for hesitation, and the proper inference to be drawn from it is the propriety of caution in action. The warning thus conveyed may be in itself most salutary, if only by discrediting the more presumptuous counsels of the sciolist and the charlatan. With regard to quackery itself, whether public or private, I do not believe it can ever be extinguished, or even materially repressed by legislative enactments. It is a necessary consequence of the imperfections of our art—a natural expression of impatience with them. Health is a jewel of such inestimable value—in such universal request—that when the mine of knowledge proves unable to furnish it, the gutters of ignorance and imposture will ever continue to be raked in the futile hope of finding it there. The best, if not the only means, in my opinion, of discountenancing the unprincipled empiric, is to maintain and try to elevate still further our own character, individually and collectively, for candour, philanthropy, and science. Those, however, who may wish to enforce the law against unqualified practitioners, will find facilities for doing so in the Medical Protective Society, which is amalgamated with our own.

I have now, gentlemen, sketched feebly, and, I fear, tediously, the nature and purposes of our Society, as I conceive they are or might become. I had intended a discourse of another kind, and haply of more general interest; but on reflection it seemed that, at this particular juncture in the lifetime of our association, it might be expedient to recall the objects of its existence, and attempt to impress them afresh on the attention of its godfathers and guardians. Certainly without a lively sense of these, and a steady conviction of its capacity for effecting them, we are little likely to secure for the “*Ulster Medical Society*” length of days or energy of action. But *possunt qui posse videntur* and worked and wielded with a will we shall make of it, I feel assured, a powerful instrument for advancing knowledge, promoting friendly feeling, and maintaining professional credit. Even in aiming at such ends, we shall not only merit the support of our own body, but become

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

entitled to the esteem and countenance of the general public.

Dr. James Moore on behalf of the Society returned thanks to the President. Dr. Patterson proposed that the address be published, Dr. Cuming suggested the propriety of its publication in the local papers. Dr. Dill was opposed to the publication of such addresses in the news-papers. Drs. Thomas Reade and MacCormac spoke in favour of Dr. Cuming's suggestion.

Dr. James Moore moved and Surgeon Gribbin seconded that the President's address be given by the council to the news-papers for publication which was agreed to.

Dr. John Moore proposed a vote of thanks through Dr. Wales to the donor of some pathological paintings, lately presented through Dr. Wales. Professor Reid seconded this and it was unanimously adopted.

Dr. James Moore expressed his intention of presenting to the Society a bust of the late Dr. McDonnell.

Surgeon Gribbin addressed the meeting on the subject of a grievance under which he considered himself to suffer by his having been brought to an inquest at which he was not examined and for his attendance at which he received no fee. This matter was referred to the council to [assess?].

Dr. McCrea presented a copy of a memorial sent by Dr. Rea to the authorities of Dublin Castle complaining of a fee of £1.1.0 having been tendered to him for 4 days attendance at the court of Quarter Session. This was referred to the council also.

John S. Drennan

484 Notice of meeting on 17th November 1866

President.

Dr. Drennan.

Ex-President.

Dr. James Moore.

Vice-Presidents.

Dr. H. S. Ferguson.

Dr. Scott, Aghnacloy.

Dr. W. Mac Cormac.

Dr. Graves, Cookstown.

Members of Council.

Dr. Stewart.

Dr. Whitaker.

Dr. Patterson.

Dr. Murney.

Dr. M'Crea.

Dr. Rea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore.

Mr. R. H. Newett.

The Seventh Meeting of the Present Session will be held in the General Hospital, on Saturday, the 17th of November, at Three o'clock, P.M.

Business.

Member to be Proposed:

John Martin, L.R.C.S.I.

Paper to be Read. by Dr. Browne

On a Case of Injury to the Liver and Kidney, with fatal termination, caused by a vehicle accident.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 15th November, 1866.

November 17, 1866

Present, the President in the chair, Drs. Stewart, Browne, Patterson, John Moore, Wales, William MacCormac, Mr. Newett, McCrea and D. N. Moore.

The minutes of the former meeting were read and confirmed.

The minutes of the last meeting of Council held on the 15th inst were also read and which stated that the members of the Council were perfectly satisfied with the explanation given by Dr. Dill in reference to a complaint made by Mr. Gribbin and were further of opinion that Dr. Dill's conduct in his official position as Coroner was not a subject which came within their jurisdiction. The subject of medical fees for attendance at Quarter Sessions Court was also brought under notice, it having been fixed by the Authorities at Dublin Castle at £1.1.0 per day.

Dr. Browne read an interesting paper on the case of a boy who had met with an accident from a cart passing over him, by which both the right kidney and liver were lacerated. The boy survived this serious accident from October 4th to November 7th and ultimately sank from abscess involving the injured kidney and destruction of the surrounding parts.

The Secretaries were directed to summon a meeting of Council for Wednesday next the 21st inst.

Proposed by Dr. Patterson that John Martin L.R.C.S.I. be elected a member of the Society.

John S. Drennan M.D.

Dr. H. S. Ferguson. Dr. Scott, Aughnacloy.
Dr. W. Mac Cormac. Dr. Graves, Cookstown.

Members of Council.

Dr. Stewart. Dr. Whitaker.
Dr. Patterson. Dr. Murney.
Dr. M'Crea. Dr. Rea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore. Mr. R. H. Newett.

The Eighth Meeting of the Present Session will be held in the General Hospital, on Saturday, the 1st December, at Three o'clock, P.M.

Business.

Member to be Ballotted for:

John Martin, L.R.C.S.I.

Pathological Specimen.

Mr. H. M. Johnston will exhibit specimen of Cancer of the Uterus.

Cases to be Read.

Dr. H. S. Purdon will read case of Tertiary Syphilis, and exhibit portion of Diseased Bone.

Dr. John Moore will read case of Inversion of the Bladder.

Recommendation from the Council.

That the Medical Journals lie on the tables in the New Rooms of the Society for a fortnight after receipt.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 28th November, 1866.

1st December, 1866

Members present, the President Dr. Drennan in the chair, Dr. Cuming, H. Brown, Dill, W. MacCormac, McWilliam, Moore, John Moore, Patterson and Stewart, Messrs. Johnston and Newett. Staff Surgeon Major Crocker was also present.

The minutes of former meeting were read and con-

firmed.

The recommendation of Council "that the journals be permitted to lie on the tables in the new rooms of the Society for a fortnight after receipt", was taken into consideration and referred again to the Council for further consideration, and a special meeting of the Society was directed to be called, the day of meeting being left to the Council to determine.

It was proposed by Dr. Patterson and seconded by Dr. John Moore that Mr. John Martin L.R.C.S.I. L.A.H. be elected a member of the Society. Elected unanimously.

Mr. H. M. Johnston exhibited a specimen of malignant disease of the uterus.

Dr. Dill considered that the case had not been malignant in the first instance but had become so.

Dr. Reade suggested that the specimen be submitted to microscopic examination which Professor Cuming undertook to do.

Dr. John Moore read a case of inversion of the bladder. Mr. H. M. Johnston related a similar one which occurred in his practice some years ago. Dr. W. MacCormac referred to the extreme rarity of such cases especially in adults, the few cases on record nearly all occurred in children. Dr. Patterson had seen one case which had been under Dr. Simpson's care in Edinburgh.

W. MacCormac V.P, Chairman
December 15th, 1866

524 Notice of meeting on 11th December 1866

President.

11th December, 1866

Special Meeting of Society

Members present, Dr. Drennan (President in the chair), Drs. Stewart, Patterson, William MacCormac, Moore, Pirrie, Murney, H. Thompson, Stephenson, Whitaker, D. N. Moore, John Moore, McCrea and Mr. Newett.

The President explained the object of the present meeting of the Society which had been called for the purpose of making such arrangements as would facilitate the members having access to the journals and to appoint a deputation to wait upon the Hospital Committee to ascertain the exact position of the Society with regard to the new rooms which have been set apart for the Society's use.

Dr. Patterson moved that rule 24 with reference to the journals be carried out. Dr. Stewart seconded it.

Dr. Murney suggested that the Society should allow the periodicals to remain on the table of the present library and to use it has a reading room to which he believed the Hospital Committee had not the slightest objection.

Drs. William MacCormac, Pirrie and Murney (joint Trustees with Mr. Girdwood for the erection of the new Wing to the hospital, the donation of Mr. Charters) were present and concurred in stating that both rooms in the basement of the wing had been specially prepared, and were intended for, the Society's use: all the expenses of preparation having been defrayed out of a supplementary grant of £500 from Mr. Charters. Under the circumstances this statement being considered quite satisfactory, the intention of applying to the Hospital Committee as to the Society's tenure of the Rooms was abandoned.¹

Dr. Stephenson stated that the elliptical table at present in the library was a gift of the late Mr. John Aicken to the Society and Dr. Patterson stated that he had purchased on behalf of the Society the seats which match the table together with six chairs which

¹ [Item 488 has the same date and almost identical wording to this paragraph, and so has not been separately transcribed.]

are still the Society's property.

John S. Drennan

525 Notice of meeting on 15th December 1866

President.

Dr. Drennan.

Ex-President.

Dr. James Moore.

Vice-Presidents.

Dr. H. S. Ferguson.

Dr. Scott, Aghnacloy.

Dr. W. Mac Cormac.

Dr. Graves, Cookstown.

Members of Council.

Dr. Whitaker.

Dr. Patterson.

Dr. Murney.

Dr. M'Crea.

Dr. Rea.

Treasurer.

Dr. Cuming.

Secretaries.

Dr. John Moore.

Mr. R. H. Newett.

The Ninth Meeting of the Present Session will be held in the Society's Rooms, at the General Hospital, on Saturday next, the 15th December, at three o'clock, P.M.

Business.

Pathological Specimen.

Dr. Smith will exhibit a Brain, the subject of recent and extensive hæmorrhage.

Case to be Read.

Dr. Murney will give the particulars of a case in which he performed Pirogoff's Amputation, and show the parts removed.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Society's Rooms

22nd December, 1866

Members present, Dr. Drennan (President in the chair), Drs. Cuming, Dill, Moore, D. N. Moore, John Moore, Patterson, William MacCormac, Stewart and Mr. Newett.

The minutes of former meeting were read and confirmed.

Dr. William MacCormac stated that he had submitted the minutes of former meeting which referred to the Society's tenure of its new rooms, to Drs. Murney and Pirrie in writing and both these gentleman agreed with him that it was correct.

The Treasurer then laid before the Society a statement of its Receipts and Expenditure for the year.

John S. Drennan

486 Notice of meeting on 5th January 1867

President.

Dr. Drennan.

Ex-President.

Dr. James Moore.

Vice-Presidents.

Dr. H. S. Ferguson.
Dr. W. Mac Cormac.

Dr. Scott, Aughnacloy.

The Tenth Meeting of the Society will be held in their Rooms, at the General Hospital, on Saturday next, the 5th January, at Three o'clock, P.M.

Business.

Mr. H. M. Johnston will read a case of Strangulated Hernia in which he operated, and which terminated fatally. He will also exhibit the strangulated portion of bowel.

Dr. Smith will read a case of Uremic Poisoning, and exhibit the recent parts.

Dr. W. Mac Cormac will give an account of a case of Dislocation of the Humerus, in which he effected reduction after eleven weeks, and will exhibit the patient.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore,
R. H. Newett,
Secs.

Belfast, 3rd January, 1867.

5th January, 1867

Members present, Dr. Drennan (President in the chair), Drs. Reade, Murney, Smith, William MacCormac, H. Brown, Whitaker, David Moore, Cuming, John Moore, Messrs. Martin, Gribbin and Newett.

Dr. William MacCormac presented a patient to the Society and read the details of his case in which he had affected reduction of a dislocation of the humerus eleven weeks after the accident had happened.

[Paper: See page 1524.]

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

451 **Letter from Mr. Henry Greer**

31 High Street Belfast
January 5th 1867

Dear Sir

I enclose a prospectus of the Belfast Athenaeum which I propose directing myself and expect to get into the new rooms 22 Castle Place early next week.

In connection with this I respectfully request that you will make the following proposition to the Ulster Medical Society.

“If the members of this Society to the number of fifty subscribe 31/6 each annually I offer them all the privileges of the institution in so far as the Reading room and Smoking room exist or may exist and I may mention that it may never be in my power to make this offer again as there are several other societies which have promised to use the Rooms when ready if I can accommodate them. I give you therefore the first offer”

H.G.

January 19, 1867

Present, the President Dr. Drennan in the chair, Drs. Stewart, Patterson, Croker, and Messrs. Gribbin and Newett.

The minutes of last meeting were read and confirmed.

The Council reported that it was not advisable to entertain Mr. Greer's proposal concerning the Athenaeum.

There was no further business transacted.

John S. Drennan

February 2nd, 1867

Present, Dr. Drennan (President in the chair), Drs. Stewart, Patterson, Murney, Wales, Smith, H. Brown, John Moore and Mr. Newett.

Dr. Smith read the history of a case of cirrhosis of the liver, in which the operation of tapping had been performed several times in order to remove the fluid which had accumulated in the abdomen. On the last occasion that operation had been performed by Dr. Murney at Dr. Smith's request. Towards the end of the operation a considerable amount of blood flowed through the cannula and notwithstanding every effort to arrest the flow, by passing a needle deeply through the walls of the abdominal parietes and twisting a ligature round it, it was evident that internal hæmorrhage was still progressing and the patient sank a few hours afterwards.

A post-mortem examination was obtained which shewed that in the operation which proceeded that which terminated so unfortunately, a portion of peritoneum had been injured, and a circumscribed point of adhesion not larger than the cannula, had taken place between it and the abdominal parietes where

the trocar had entered. As the same point was again selected for aspiration a vein was wounded, and from this unique accident the fatal hæmorrhage took place.

Dr. Murney had not been able to find the record of any similar case in all the journals to which he had access.

Dr. Moore stated that his father who had great experience in tapping seldom selected the same spot for a second operation. Should such a case occur in his practice he would pass a [joile?] needle deeply and twist a ligature round it.

Dr. Murney presented a patient in whom he had performed Pirogoff's amputation of the foot sometime ago and from which an excellent stump resulted.

John S. Drennan, President

16th February, 1867

Members present, Dr. Drennan (President in the chair), Drs. Reade, Cuming, Stewart, Moore, W. Mac-Cormac, H. Browne, McMurtry, John Moore and Mr. Newett.

A telegraphic message having been received from Dr. Porter regretting his unavoidable absence, the reading of his paper was consequently deferred to next meeting.

No other business was transacted.

John S. Drennan

Belfast, 28th February, 1867.

2nd March, 1867

Members present, Dr. Drennan (President in the chair), Drs. Reade, Stewart, Cuming, W. MacCormac, Whitaker, McMurtry, Moore.

Dr. Porter read a case of Phagedænic Chancre of Dorsum Penis followed by Sclerotitis and Keratitis.

Paper:¹ *On the 16th of last December, A. C. M., a married mechanic, was brought to me for a sloughing sore on the dorsum of his penis, which he first noticed as a small abrasion a fortnight before. On examining, I found it to be about the size of a florin, the surface an ashy grey, discharging a greenish ichor; the edges ragged and high, and the base flabby, nonindurated. The cellular tissue of the prepuce was infiltrated to a great extent, but the dorsal lymphatics did not appear in the least implicated, nor had he at this time any sign of bubo in either groin.*

On questioning him as to his habits and health he told me he occasionally drank freely, was exposed to heats and colds, had a variable appetite, and was not accustomed to very good food. The bowels were regular. He was not aware of suffering from any complaint but the one for which he wished me to treat him, and was not aware of ever having had venereal disease before. He was in a painfully nervous state, and this he attributed to loss of sleep. He had been poulticing the sore on his own responsibility for several days, and had also drugged himself with senna and salts; his pulse was quick and thready, his tongue creamy, and his complexion sallow.

With the assistance of his companion, I put him slightly under the influence of chloroform, and freely cauterized the chancre with strong nitric acid; applied a piece of lint dipped in a mixture of glycerine and water, over this oiled silk, and a small, light bandage, in which I included the swollen foreskin; ordered him to

keep a poultice of linseed meal to the sore during the night, and renew it next day; to support the yard on his abdomen by means of handkerchiefs; and get to bed as soon as practicable. I gave him twenty grains of Dover's powder to be taken at eight o'clock, and prescribed five-grain doses of Plummer's pill, night and morning. On his leaving he appeared much more tranquil, the pain of the operation having almost passed away.

On Tuesday, the 18th ultimo, according to arrangement, he called with me; had of necessity been at his work the preceding day, but had not suffered much pain: had slept well during the night, and did not appear in the least agitated or nervous; his bowels had been freely opened in the morning; the ulcer was now deeper than the skin, and discharging thin yellow pus; the edges were high and the margin inflamed. Into the centre of the ulcer I dropped a little of the red oxyde of mercury, and having smeared the intact skin with a mixture of collodion and glycerine, applied a weak lotion of nitric acid, and bandaged up the penis against his abdomen. Prescribed the compound decoction of sarsaparilla, in one ounce doses, three times daily. Before he left, I found on enquiry a large bubo had appeared in his right groin—the side corresponding to the larger half of the chancre on the dorsum penis. I recommended a poultice of linseed meal to be kept to it, and the weak nitric acid lotion to be renewed to the chancre when required.

On Thursday, the 20th ultimo, the ulcer presented a red granulating surface, with healthy pus; the edges were less inflamed, and level with the sound skin. Ordered frequent applications of black-wash; the bubo was large and painful; I opened it, and obtained a good quantity of curdy matter, very dark coloured; he experienced great relief from this; I then painted the skin over and about with tincture of iodine; I stopped giving him the compound calomel pill, as he had now taken in all half a drachm of it, leaving him on the compound decoction of sarsaparilla as his only medicine.

Christmas day, the 25th ultimo, the ulcer was healing rapidly; his general health was good; he had been living more generously for the previous four or five days, and taking his food with relish; had slept well, and did not appear to suffer from febrile excitement.

On the 27th ultimo the new skin had begun to form from the edges, the bowels kept regular, and the appetite and spirits good; I painted the bubo with tincture of iodine; it had almost disappeared, as had the swelling of the prepuce.

On the 28th ultimo the ulcer was nearly healed, there being but the size of a groat of granular surface.

On the 29th ultimo the ulcer was covered with new skin, except a very minute patch; no traces of the bubo remained, save a little hardness. On this date he discontinued the compound decoction of sarsaparilla as recommended. He now left me, thinking he was cured.

¹ [Medical Press and Circular, 1867, p310.]

On the fourth day of this month (January), he came back to me complaining of a sore throat; he thought he had caught cold, and evidently had.

On examining his throat I found the uvula full and congested, with a similar condition of the right tonsil, and diffuse erythema of the fauces, but could not detect ulceration of any kind. He was feverish and nervous, and seemed to apprehend something unpleasant.

Recommended frequent alum water gargles, and gave him a powder composed of two grains of calomel with twenty grains of Dover's powder, to be followed in the morning by a dose of salts; his bowels had not been acting for two days, and this condition seemed to aggravate his symptoms. Before leaving, he directed my notice to the smarting of his eyes, and congestion of the conjunctivæ, which, however, was very slight

On the 5th inst. the chancre was quite healed; the throat was slightly better, but the conjunctiva of the right eye was greatly inflamed, that of the left eye less so; I touched the palpebral portions of the membrane with the stick nitrate of silver; gave twenty grains of Dover's powder; ordered two leeches to the temple, and dreading the possibility of syphilitic poison having something to do with this acute attack, immediately put him on the bichloride of mercury, prescribed in the following form:

℞ Hyd. bichlor. gr. ii.

Tr. hyoscyam. zii.

Vin. colchici.

Vin. ipecac. aa. ℥ss.

Infus. gent. co. ad ℥iv. M. ft. mist.

A teaspoonful to be taken in a glass of water three times daily as directed; recommended as nourishing food as his means would permit of, warm clothing, and, as far as possible, avoidance of exposure.

He had to leave off work on this date, owing to the intense pain; his nervousness was excessive, and the application of the caustic seemed to excite him very much.

On the 7th inst., he came to me in great alarm, saying his eye was much worse; he was suffering extreme pain in the brow and temple, which at times he referred to the deeper structures of the ball; he had most marked photophobia of the right eye; the tears ran from both on examination, but principally from the right one, the left conjunctival membrane seemed much improved, and the congestion greatly lessened, but on the right side the inflammation had extended, and the subjacent tunic become involved, as indicated by the straight pink coloured vessels to the inner side of the cornea, which were visible for a limited extent, running from the margin of the blueish white ring, and terminating in the capillary net work of the conjunctiva; the pupil was at this time dilated.

The soreness of the throat had passed away; his bowels were regular, but his appearance was haggard and worn from want of sleep. Ordered two leeches to

his temple, and twenty grains of Dover's powder to be taken at bed time; the bichloride of mercury mixture he was taking regularly.

On the 8th inst. the inflammatory action of the left eye had disappeared, while in the right eye it had decreased in the conjunctiva, but increased and extended in the sclerotic to the inner side of the cornea, round which the blueish white ring had become more opaque; the cornea itself was still clear, with the pupil contracted. He had great dimness of vision; intolerance of light, and profuse flow of tears, supra-orbital pain, and severe headache, accompanied by a good deal of febrile excitement. Recommended a full dose of Dover's powder, and hot fomentations to the eye, the other treatment being strictly pursued.

The following day (9th inst.) he returned in a state of distraction, more, however, from the dread of evil results than any pain he suffered. On raising the lid I found the whole cornea had become opaque, completely obscuring the pupil, he could not see at all with this eye. The pink coloured vessels of the sclerotic were very distinct to the inner side, while very little congestion remained in the capillaries of the conjunctiva. Prescribed ten drops of the tincture of perchloride of iron every hour, the bichloride of mercury being continued as before, and as a collyrium:

Ext. Belladon. gr. xx

Zinci Sulph. gr. xl.

Aquæ distill. ℥iv. M.

The full of a small syringe to be injected under the lids four times daily, while with me I used some of this to his eye, and though painful at the time, he experienced great relief after it, accompanied by intense itching. Recommended a blister behind his right ear, and gave him a Dover's powder to take at bed time.

I did not see him on the 10th inst., but visited him at his own house on the 11th; his friends had refused to give him his medicines, or otherwise carry out my instructions. I then found it necessary to tell his wife the previous history of his case, in order that she might afterwards permit him to go by my advice.

On exposing the eye, considerable congestion of the conjunctival capillaries, more diffuse and extensive inflammation of the sclerotic membrane on all sides, less opacity of the cornea, and a more dilated pupil, were the appearances observed; though the pupil was now apparent he could not in the least degree distinguish light from shade. The treatment was now resumed, and the blister applied.

On the 12th inst. I learned that all directions had been strictly attended to, the changes presented by the eye were more general redness of the conjunctiva, and deeper colour in the radiating capillaries of the sclerotic, the condition of the cornea remaining unaltered; his pulse was sixty in the minute, steady and full; his tongue clean; appetite good; and nervous excitement much less; his throat he did not now complain of, nor

did it present an unhealthy state; on this occasion some extract of Belladonna was smeared round the orbit of his affected eye.

The 13th inst., the conjunctival congestion was less, and confined to the inner side of the membrane, there was less opacity of the cornea, and greatly diminished vascularity of the sclerotic; the pupil was more dilated; the tongue was clean; pulse 65, regular; his throat was rather inflamed-looking; he appeared in excellent spirits; had a good appetite, and was now, as recommended, taking two bottles of porter in the day; ordered a cathartic pill to relieve constipation.

On the 14th inst. the inflammatory action of the membranes was rapidly decreasing, the sclerotic vascularity remained round the margin of the cornea, but the colour of the vessels was much lighter; the cornea itself had begun, to regain its transparency, the pupil was large, his general health and spirits kept good, his bowels had been freely moved, and his throat seemed better: he now stated he could discern light and shade with the diseased eye.

On the 16th inst. the improvement in the eye was marvellous: the cornea was almost quite clear again, the pupil was widely dilated, the redness of the conjunctiva was very slight and confined to the neighbourhood of the inner canthus; the radiating vessels of the sclerotic were still visible, but less distinct; his health and spirits continued excellent, he had a keen appetite, his tongue was clean, and his throat much better.

On the 17th inst. the improvement developed in the eye within the space of twenty-four hours was such that he could again distinguish objects; the opacity of the cornea had become absorbed, and it had almost returned to its normal state; a lingering inflammatory blush still remained in the sclerotic; the neighbourhood of the inner canthus seemed to have a little more redness than on the preceding day, but it appeared he had gone out into the cold air, and this may have accounted for the latter symptom.

On the 18th inst. he could see quite as well with his right eye as with the unaffected one, but the weakness which still remained prevented his looking at any object for more than a minute at a time. The sclerotic vessels still imparted a pink hue to the white of the eye; all conjunctival redness was gone. The blueish-white ring which encircled the cornea had greatly diminished. The bichloride of mercury was finished.

On the 19th inst. the cornea was quite transparent, but considerable vascularity remained in the sclerotic. His health kept good, and he had commenced to take cod liver oil. Did not renew the corrosive sublimate, of which he had taken, in all, two grains.

On the 21st inst. the eye was much stronger, and the sclerotic vascularity greatly lessened; the bowels had been freely moved. The cod liver oil seemed to agree with his stomach. The right tonsil was inflamed, and caused him some uneasiness in swallowing.

He was at his work the following day; he felt his eye getting stronger, and his throat better; he had applied a mustard and linseed poultice externally to it during the night, and received great relief from it.

On the 25th inst. every trace of inflammatory action had left, and the eye presented a normal appearance. He could now see almost as well as ever he had done. His throat being still a little troublesome, was cauterized with a strong solution of nitrate of silver. He kept in excellent health, and found the cod liver oil agreed well with him, as did the tincture of perchloride of iron, of which he was now taking fifteen drops three times daily.

The next day his throat, though better, was again cauterized. His eye was being strengthened by douches of cold water applied night and morning.

On the 28th inst. his throat was cauterized, and appeared greatly improved. He did not find any injurious effects from being at his work.

On the 30th instant his throat was much improved, and he could swallow without pain. I recommended him a mixture of chlorate of potass and tr. of steel, with infus. of quassia. I now considered him free from the malady for which he originally came to me, and discontinued my visits, believing the throat affection to be due merely to simple congestion of the mucous tract.

In reviewing the history of the case, some peculiarities may be observed, while the treatment adopted is perhaps deserving of a little consideration.

Mr. Henry Lee has described four varieties of chancre viz., the Hunterian or true, the non-indurated or soft, the phagedænic, and the gangrenous or sloughing chancre; the third is most like the form presented in the foregoing report, but yet materially different. Mr. Lee in speaking of it says—"It produces suppuration, generally of one inguinal gland only, which yields an inoculable secretion. It is not followed by constitutional syphilis, and may be treated by local means."

In this patient it has been seen that one inguinal gland only suppurated, but that constitutional symptoms ensued, and these—neither preceded nor accompanied by any eruption of the skin—were confined to the right side of the body, and supervened on the healing of the primary sore; that there was no induration, and the chancre exhibited the process of ulcerative inflammation (vide "A System of Surgery," edited by T. Holmes, M.A., &c., vol. i., p. 461). It was seen that the right tonsil and uvula were congested and swollen, while no ulcers could be detected on any portion of the mucous membrane of the mouth or throat. These facts, together with the nature and course of the diseases which attacked the eye, do, I think, give an uncommon aspect to the whole case.

As noticed, the treatment pursued was successful, and throughout unattended by ptyalism, or other indications of mercurialization, which were carefully watched for, in order that the use of mercury might be

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

suspended or stopped should such arise. From the first, the strength was supported by a nourishing diet, and the irritation allayed by full doses of Dover's powder. A small amount of Plummer's pill was administered at the early stage, but merely with the object of acting on the skin, liver, and bowels, not as a prophylactic. The cauterization with strong nitric acid, and the subsequent local applications, having been attended by good results, and unaccompanied by any considerable amount of inflammation or constitutional disturbance, give sufficient evidence in their own favour. When the eye affections became apparent and the mercurial treatment was indicated, a mixture containing corrosive sublimate, in combination with henbane, colchicum, and ipecacuanha, as already observed, was adopted, the blood being at the same time strengthened by tincture of steel, in large and frequent doses, and this supplemented by cod-liver oil. The speedy resolution of the inflamed membranes, and the improvement which took place in the general health, may be spoken of as consequent on the treatment to which the system was subjected.

Professor Cuming complemented Dr. Porter on this his first paper presented to the Society and characterised it as being especially well written, but was of opinion that the eye affection which followed was not a consequence of the syphilitic disease but a mere coincidence.

Dr. William McCrea coincided in opinion with Dr. Cuming and looked upon the inflammation of the eye as not syphilitic.

Dr. Reade thought there might be some connection between the two ailments and considered the case as one worthy of further observations.¹

Robert Stewart, Chairman,
16th March, 1867

528 Notice of meeting on 16th March 1867

President.

Dr. Drennan.

Belfast, 14th March, 1867.

16th March, 1867

Members present, Drs. Stewart (in the chair), Drs. Reade, Patterson, Dill, Cuming, William MacCormac, McWilliam, Wales, John Moore, Mr. Newett, Dr. Smith, Porter, H. Brown.

Minutes of former meeting read and confirmed.

Dr. William MacCormac gave an account of three cases of hæmorrhoids on which he had operated by the clamp and the actual cautery, and also gave the particulars of a case of strangulated femoral hernia successfully operated on.

The operation for piles was illustrated by a well-executed drawing of the diseased parts.

The first case operated on was J.E. æt. 43. Had suffered from the complaint for twelve years, at times it amounted to agony. Exhausting hæmorrhages took place and his general health was broken down.

The bowel having been emptied by an enema, the patient was placed on his left side, and the pile taken hold of by a pair of forceps with which it was drawn downwards.

Its base was then partially snipped through with a pair of scissors and the remainder enclosed in the clamp. The pile having been then removed with the scissors, the actual cautery was then applied, and the bowel returned to its place.[$\frac{3}{4}$ grs?] of opium with [3 grs?] of Tannin were ordered every third hour.

¹ [See further remarks on page 1086.]

After the first hour all pain and uneasiness subsided. The fourth day after the operation a draught of castor oil followed by a tepid water injection caused the bowels to be opened without suffering. He was discharged twelve days after the operation quite cured and most thankful.

The other cases did not differ materially from the foregoing.

Drs. Dill and Reade made some observations on the cases.

John S. Drennan, President

March 30th, 1867

Present, the President in the chair, Drs. Cuming, Patterson, Stewart, Reade, Moore, Dill, Wales, Henry Browne, Porter and Mr. Newett.

The President read papers on a case of tubercle of the brain and on a case of abscess of the liver. Preparations were exhibited and a discussion ensued.

John S. Drennan

April 13th, 1867

Members present, Dr. Drennan (President in the chair), Drs. Stewart, Patterson, Moore, H. Brown, William MacCormac, H. Purdon, Dill, John Moore and Mr. Newett. Dr. Croker, Staff Surgeon, was also present.

Minutes of former meeting read and confirmed.

Dr. Moore exhibited an elongated prepuce which he had removed by circumcision from a gentleman who was about to get married, and to the duties consequent on such a state, the encumbrance would have presented a serious obstacle to their proper performance.

He also exhibited a diseased testicle which he had removed. The subject of the operation received a blow from an Aunt Sally stick on the testicle sometime previously. This was followed by severe inflammation and a swelling which never entirely disappeared.

Ulceration at length took place and an amount of disorganisation to such an extent as required removal of the diseased organ.

Dr. William MacCormac read a case of inguinal hernia which occurred in a woman and on which he had operated. The subject was a domestic servant age 52 years. The rupture had existed from childhood. On the 3rd inst. strangulation of the bowel took place and for a time she concealed the nature of her ailment. Stercoraceous vomiting occurred when the case was seen by Dr. Pirrie. Not being able to reduce the strangulated bowel, he sent for Dr. MacCormac and it was agreed to place the patient under chloroform and should the taxis not prove successful, to proceed at once to divide the stricture. Not succeeding, the operation was undertaken and on opening the sac the portion of bowel forming the rupture was found to be the cæcum with the vermiform appendix. Consider-

able difficulty was experienced in returning the bowel which was at length accomplished. This was followed by great relief and all the urgent symptoms subsided. For the first twenty-four hours she continued to progress most satisfactorily but afterward unfavourable symptoms appeared. The wound shewed no tendency to heal but it was not till the 7th, four days after the operation that alarming signs presented themselves when rapid sinking came on and she died at 8 p.m. on that day.

A P.M. was obtained which failed to throw much light on the cause of death. The bowels were distended with air but there were no signs of general peritonitis. There was some lymph at the constricted portion of the bowel but no perforation and Dr. MacCormac was still unable satisfactorily to account for the cause of death in this case. He considered it his duty to bring the case forward as from such as terminate unfavourably more may often be learned than from those which end well.

Dr. Moore, Dr. Cuming and the President made some observations on the case.

John S. Drennan, President

26th April 1867

Members present, the President in the chair, Drs. Reade, Stewart, Patterson, Cuming, H. Brown, John Moore and Mr. Newett.

Minutes of last meeting read and confirmed.

Dr. Cuming proposed and Dr. Patterson seconded that Dr. Fagan be elected a member of the Society. Elected unanimously.

The Secretaries were directed to summon a Special Meeting of Council for Thursday 2nd May at 12 o'clock to prepare the Annual Report for the Society and to transact such other business as may be brought before it.

Dr. Patterson proposed and Dr. Stewart seconded that Drs. Whitaker and H. Brown be appointed Auditors for the ensuing year. Carried unanimously.

James Patterson, Chairman
1st June 1867

Annual Report of Council

The Council has much pleasure in submitting to the members of the Society their Report for the year just terminated.

Twenty meetings have been held at which the following instructive papers were read, pathological specimens exhibited, and interesting cases presented.

Papers by Professor Cuming on pericarditis with unusual cerebral symptoms.

Professor Seaton Reid on recent cholera cases in Belfast.

Dr. John Moore on a case of inversion of the bladder.

Ulster Medical Society
Session 1866–1867
President John Swanwick Drennan

Dr. J. W. T. Smith on a case of unusual local spasmodic affection, on uræmic poisoning, and on cirrhosis of liver where fatal hæmorrhage followed tapping, performed at his request by Dr. Murney.

Dr. Porter on phagedenic chancre of dorsum penis followed by sclerotitis and keratitis.

Dr. William MacCormac on cases of hæmorrhoids operated on by the clamp and actual cautery, and on cases of hernia operated on by him.

Pathological specimens exhibited by Professor Cuming of fibrinous concretion of the heart.

Dr. Browne a ruptured liver and kidney resulting from a wagon passing over the body of a boy.

By Dr. James Smith a brain the subject of recent and extensive hæmorrhage.

Dr. James Moore an elongated prepuce and a diseased testicle which he had removed.

Patients were presented by Dr. William MacCormac where reduction of the humerus had been effected eleven weeks after the accident.

Dr. Murney where he had performed Pirogoff's amputation of the foot.

Fourteen members joined the Society during the year, Drs. Drennan and Wheeler becoming life members. The Society has lost by death one of its oldest and most respected members, Dr. McMechan of Whitehouse.

One case of misunderstanding between two members of the Society was referred to the Council and amicably arranged.

The following is the attendance of members at meetings of Council: Dr. Drennan 15, Dr. James Moore 7, H. S. Ferguson 0, William MacCormac 14, Scott 0, Graves 0, Stewart 12, Patterson 10, McCrea 1, Whitaker 3, Murney 3, H. P. Rea 1, Cuming 8, John Moore 15, Mr. Newett 19.

On the 6th October the Society entered into possession of the new Rooms which have been set apart for its use and on the 11th December a Special Meeting of the Society was held when the following minute was entered on the records of the Society: Drs. William MacCormac, Pirrie and Murney, joint Trustees with Mr. Girdwood for the erection of the New Wing of the hospital, the donation of Mr. Chartres were present and concurred in stating that both rooms in the basement of the Wing had been specially prepared and were intended for the Society's use all the expense of preparation having been defrayed out of a supplementary grant of £500 from Mr. Chartres.

The Council regret to state that though they have given their best attention to the circulation of the periodicals they have been unable to make as satisfactory arrangements as they would desire.

It would further desire to call the Society's attention to the fact that the Library Room of the Society being now so occupied by the Committee of the General Hospital as to render it unavailable to the mem-

bers as a reading room for which purpose it was originally set apart; the Council are of opinion that their claims upon it should be laid before the Committee and a distinct undertaking arrived at in the subject.

John Moore M.D., Secretary
1st May 1868 R. Stewart, Chairman

Society's Rooms

4th May, 1867

Annual Meeting

The President in the chair, members present, Drs. Thomas Reade, Stewart, Patterson, Cuming, William MacCormac, Whitaker, H. Brown, T. H. Purdon, James Smith, Brice Smyth, John Moore, Messrs. Newett and Martin.

Dr. Monck of Holywood was elected a member of the Society having been proposed by Dr. James Moore and seconded by Dr. Patterson.¹

The minutes of last Annual Meeting were read and confirmed.

The Report of the Council for the past year was read. It was then moved by Dr. Drennan and seconded by Dr. William MacCormac that the Report just read be adopted and entered on the minutes of the meeting. Carried unanimously.

The Treasurer then laid before the Society a statement of its accounts for the past year.

The members then proceeded to the election of a President and Office Bearers for the ensuing year.

Dr. Seaton Reid was unanimously elected President of the Society. Drs. Thomas Reade and James Smith, Vice Presidents for Town, Drs. Kelso of Lisburn and H. Thompson of Bangor, Vice Presidents for Country.

The following were elected Members of Council, Drs. Patterson, Stewart, William MacCormac, T. H. Purdon, Whitaker, Brice Smyth.

Dr. Cuming was requested to continue as Treasurer and Dr. John Moore as Secretary to the Society, which both consented to do.

Dr. Thomas Reade proposed that the best thanks of the meeting be given to Dr. Drennan, the retiring President, for the admirable address which he had delivered (and which at the Society's request has been published), for his constant attendance at the meetings of the Society, and for the uniformly kind and efficient manners in which he had discharged the duties of his office which has been such as to give entire satisfaction to every member of the Society: and he only regretted that the Rules of the Society were such as to preclude his re-election, a proposition which he believed would have met with the unanimous wish of the members. Dr. Patterson seconded the proposition which was carried by acclamation.

¹ [This seems to be Charles Edward Beresford Monck.]

Dr. Drennan replied and expressed the pleasure he would at all times feel in affording to the Society all the aid which was in his power to bestow.

Dr. Stewart moved and Dr. Thomas Reade seconded that a vote of thanks be tendered to Mr. Newett for the valuable services which he has rendered as joint Secretary to the Society, and from which post he now reluctantly retires owing to the pressure of his other engagements.

489 Newspaper Clipping—Report of Annual Meeting.

Ulster Medical Society.—The annual meeting of this society was held at their rooms, in the General Hospital, on Saturday last, when the council's report for the past year was laid before the members. Twenty meetings of the society had been held, at which instructive papers were read, pathological specimens exhibited, and interesting cases presented. Fourteen new members joined the society since last annual meeting; and the council regrets to record the loss of one of its oldest and most esteemed members, Dr. M'Mechan, of Whitehouse. Dr. Seaton Reid was unanimously elected president for the ensuing year; Drs. Thos. Reade, J. W. Smith, Kelso (Lisburn), and Thompson (Bangor), vice-presidents.

The following were elected members of council Drs. Patterson, Stewart, William MacCormac, H. S. Purdon, Whitaker, and Brice Smyth. Professor Cuming was requested to continue as treasurer, and Dr. John Moore as secretary, to the society. Dr. Thomas Reade moved a vote of thanks to Dr. Drennan, the retiring president, for the admirable inaugural address which he had delivered, for his constant attendance at the meetings of the society, and for the uniformly kind and efficient manner in which he had discharged the duties of his office, which was seconded by Dr. Patterson, and carried by acclamation. A vote of thanks was proposed by Dr. Stewart, seconded by Dr. Reade, and passed unanimously, to Mr. Newett for the valuable services he had rendered as joint-secretary to the society, and from which office, owing to the pressure of his other engagements, he now retires.

493 Notice of meeting on 1st June 1867

The First Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Saturday next, the 1st June, at Three o'clock, P.M.

Business.

Specially to consider a recommendation of Council to change the day and hour of the Society's Meetings.

Paper to be Read:

Dr. H. Brown will read a Paper on the New Edition of the British Pharmacopœia.

Members in arrear are requested to forward their Subscriptions to the Treasurer.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries of Council not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.
Belfast, 29th May, 1867.

494 *Funeral of Dr. Thomas Thompson*

Undated.

The Members of the Society are requested to attend the Funeral of the late Dr. Thomas Thompson, whose remains will be removed from Elmwood Church, on Saturday Morning next,¹ at Nine o'clock, for interment in the New Burying-Ground.

John Moore, M.D.
Secretary

First Meeting Society's Rooms, 1st June, 1867

Present, Dr. Patterson in the chair, Drs. H. Brown, Whitaker, McMurtry, Fagan, McCrea, Wales, Dill, William MacCormac, Monck, Stewart, David Moore, Nevin Moore, John Moore, Messrs. Newett and Gribbin.

Minutes of last ordinary meeting read and confirmed.

The circular summoning the meeting was read and also a minute of Council Meeting in which it was recommended to change the day and hour of Society's meetings from Saturday at 3 o'clock p.m. to Friday at 7.30p.m. This recommendation was proposed as a resolution by Dr. William MacCormac and seconded by Dr. Dill. It was carried unanimously.

The Secretary was directed to have placed on the circular summoning next meeting, the day and hour to which the meeting had been changed, and notice of confirmation of resolution making such change.

The Secretary stated that as authorised by the Council he had engaged a man to distribute the journals and deliver the circulars at a remuneration of three shillings a week.

It was unanimously agreed to, that a letter of condolence be addressed to Miss Thompson on the death of her Father, one of the oldest members of the Society, and that the Secretary be instructed to write it.

Dr. H. Brown read part of an elaborate and most carefully written paper on the new edition of the British Pharmacopœia in which he brought before the members the omissions, the changes and the additions which have been made in the Pharmacopœia. He will conclude his paper at next meeting of Society.

J. Seaton Reid, Chairman

Second Meeting Society's Rooms, 6th July, 1867

Present, the President (in the chair), Drs. James Moore, Thomas Read, Patterson, Wales, H. Brown and John Moore.

Dr. James Moore exhibited a large tumour which he considered to be of a malignant nature, and which he removed from the right mamma of a lady on the 30th ult. The tumour was of about five months growth and had attained an enormous size, it was comparatively painless and the constitution had not suffered much. Several surgeons had been consulted and different opinions expressed both as to the nature of the tumour and the propriety of its removal. As the tumour was perfectly free and moveable, and the weight of the mass a source of great discomfort, it was at length decided to remove it which was done accordingly.

The hæmorrhage attending the operation was not nearly so great as might have been anticipated and was easily controlled. The patient has since progressed most favourably and the wound is healing kindly.

Mr. James Moore further detailed the history of a case of nevus in a child in which he had operated by means of passing a current of electricity through the tumour. He thought this was the first case in which this method had been tried in this country.

The following gentleman were proposed as members of the Society by the Secretary and seconded by Dr. Patterson: Dr. Hayes, Dr. H. Hanna, Mr. H. Moore, Mr. Berry.

J. Seaton Reid, Chairman

496 *Notice of meeting on 2nd August 1867*

The Third Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 2nd of August, at Half-past Seven o'clock.

Business.

Members to be Balloted for.

Dr. Hayes.

Mr. H. Moore.

Dr. H. Hanna.

Mr. Berry.

Professor Cuming will exhibit Patient, the subject of "Addison's Disease."

Pathological Specimen.

Mr. H. M. Johnston will exhibit a very remarkable case of Ruptured Uterus, in which adhesion had taken place between its fundus and the inferior surface of the liver.

Paper to be Read:

Dr. M'William will read notes of a remarkable case of Intercostal Paralysis.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

¹ [Probably 1 June but cemetery records say buried 30 May.]

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 31st July, 1867.

Third Meeting Society's Rooms, 2nd August, 1867, 7.30p.m.

The President in the chair. Members present, Professor Cuming, Drs. H. Brown, Dill, Fagan, William MacCormac, D. Moore, John Moore, Patterson, H. S. Purdon, H. P. Rea, Wales and Whitaker, Messrs. H. M. Johnston, Martin and Newett.

Minutes of former meeting read and confirmed.

Dr. Wales requested permission to introduce a patient, who was in waiting, and who was suffering from an unusual form of paralysis especially of the muscles of the pharynx, and which gave rise at times to great debility from her inability to swallow. He was anxious to ascertain the opinion of the members of the Society in reference to her case and any plan of treatment they might suggest.

Professor Cuming, Dr. Dill and others were of opinion that the case was one of hysteria, and that the remedies usually applied for that disorder might be found beneficial in this case.

Professor Cuming detailed the history of a case of Addison's disease and introduced the patient whose skin presented a very peculiar mottled appearance, some portions of the skin presenting an appearance whiter than natural and others the darkened appearance peculiar to this disease. He did not consider that the connection between the disease of the suprarenal capsules, and the bronzed skin had been yet established, but inclined to the view that is now held by most pathologists, that it depends upon an alteration of the blood discs which become broken up and this pigmentary matter becoming deposited in the skin.

Mr. H. M. Johnston laid before the Society the uterus and liver of a patient who had died in the Union Workhouse from rupture of the former during labour. She had been an inmate of the hospital for some time and her abdomen was so large that her confinement was looked forward to with some degree of apprehension. When labour set in it was weak and powerless, during the first 24 hours the pains were few and feeble but the os began to dilate and the fundus descended. The breech presented. Little progress was made during the next 24 hours, the woman being able to walk about the ward; there being no urgent symptoms present to demand interference, and pulsation of the cord having ceased it was deemed

better to wait in hopes that expulsive pains would come on and delivery be effected by natural means. About 48 hours after the commencement of labour he received a note from the Resident Surgeon requesting his attendance when he found on his arrival that she had suddenly expired a few minutes before. It was evident that rupture of the uterus had taken place, as the child had been dead for some time and the patient in a ward surrounded by others no interference was then attempted.

A post-mortem examination was made next morning when a large rupture of the uterus was found to exist from which the breech and lower extremities of the child had escaped into the abdomen. But the most remarkable point was that the liver was found enormously enlarged and diseased and that between the fundus of the uterus and the inferior surface of the liver close, firm and extensive adhesions had been formed preventing all expulsive efforts of the uterus and causing the fatal termination of the case. An interesting discussion followed in which nearly all the members present took part and the case was considered one of the most remarkable on record.

Dr. Dill was of opinion that earlier interference and delivery might have given the patient a better chance than the delay which had taken place. Dr. D. Moore and others were of a contrary opinion and believed it would only have hastened what in any case must have terminated fatally. Dr. H. Brown had examined the liver microscopically and found the disease to be malignant.

As the above case fully occupied the time of the Society Meeting on the motion of Dr. Patterson was unanimously resolved that an adjournment meeting be held on Friday evening the 16th inst. to hear Dr. H. Brown's paper on the new British Pharmacopœia which was on today's circular for this evening.

The following gentleman having been balloted for were elected unanimously members of the Society: Drs. H. Hanna and Hayes, Messrs. Berry and H. Moore. Dr. Smith proposed and Dr. John Moore seconded Dr. Thompson of Donaghadee as a member of the Society.

J. Seaton Reid

500 Notice of meeting on 16th August 1867

An Adjourned Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 16th instant, at Half-past Seven o'clock.

Business.

Paper to be Read:

Dr. H. Brown will read the concluding part of his paper on the New British Pharmacopœia. Subject,—“The Additions.” Specimens of the most important will be exhibited.

Ulster Medical Society
Session 1867–1868
President James Seaton Reid

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 14th August, 1867.

Third Adjourned Meeting Society's Rooms, 16th August, 1867

An adjourned meeting of the Society held this evening, present Professor Cuming in the chair, Drs. H. Brown, Fagan, D. Moore, James Moore, Wales and Whitaker, Messrs. Berry, Martin and Newett.

Dr. H. Brown read the concluding portion of his paper of the new edition of the Pharmacopœia.

495 Notice of meeting on 6th September 1867
The Fourth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 6th instant, at Half-past Seven o'clock.

Business.

Recommendation from Council.

That the Members of the Profession attending the Social Science Congress be entertained by the Society.

Pathological Specimens to be Exhibited.

Professor Cuming will exhibit recent parts in case of Abscess of Lung.

Dr. W. Mac Cormac will exhibit parts removed in case of Fracture of Spine; and will also exhibit parts removed in a case of Fracture of the Skull.

Dr. Smith will exhibit specimen of Cirrhosis of Liver.

Paper to be Read:

Dr. M'William will read notes of a remarkable case of Intercostal Paralysis.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 4th September, 1867.

497 Letter to the members.

10 Carlisle Terrace
Belfast, 9th September, 1867

Sir

I have been directed by the Council, to inform you that the Society, at its meeting on Friday last, resolved to entertain such of the Members of the Profession as may visit Belfast at the approaching Congress of the Social Science Association.

The form of Entertainment was referred to the Council, who decided that it should be a Dinner, and I have to request your assistance and co-operation in this manner.

An answer, not later than the 12th instant, will oblige,

Your obedient Servant,
John Moore,
Secretary.

Fourth Meeting Society's Rooms, September 1867

No minutes recorded.

499 Letter to the members.

10 Carlisle Terrace,
20th September, 1867.

Sir

I beg to inform you that the Annual Dinner of the Society, to which the Members of the Profession visiting Belfast in connexion with the Social Science Congress have been invited, will take place on Wednesday next, the 25th instant, in The Rooms of the Church of England Young Men's Association, Clarence Place, at Six o'clock.

John Moore, M.D.
Honorary Secretary

498 List of toasts at the Annual Dinner

"THE QUEEN."

"THE ARMY AND NAVY MEDICAL DEPARTMENTS."

The Vice-President.

Staff-Surgeon Major Fjennell.

Dr. M'Gee.

"THE PRESIDENT OF THE HEALTH SECTION OF THE SOCIAL SCIENCE CONGRESS."

The President.

Sir James Y. Simpson.

"SANITARY SCIENCE."

Dr. Samuel Browne, R.N.

Dr. Elliott.

Dr. Mapother

“THE PRESIDENT OF THE ULSTER MEDICAL SOCIETY.”

Sir James Y. Simpson.

“Medical Coroners”

Dr. Stephenson.

Dr. Lankester.

Dr. Davy.

“THE HUMANE TREATMENT OF THE
INSANE AND IMBECILE.”

Dr. Mac Cormac.

Dr. Skae.

Dr. Kidd.

515 Newspaper Clipping—Annual Dinner

Yesterday, the members of the medical profession attending the Social Science Congress in Belfast were entertained by the above society in the Clarence Buildings, Clarence Place. The following is the list of those present:—

Sir James Simpson, Edinburgh; Sir Robert Kane, Cork; Sir James Murray, Dublin; Drs. Lankester, London; Macadam, Edinburgh; Skae, Edinburgh; Mapother, Dublin; Aveling, Sheffield; Elliott, Carlisle; Beveridge, Aberdeen; Down, Earlswood; Hardwick, London; Robinson, J.P., Fintona, Tyrone; Stewart, Lucan; Kidd, Dublin; Mackesey, Waterford; Surgeon-Major Crocker, 3d Buffs; Assistant-Surgeon Crisp, 3d Buffs; Drs. Ffennell, Shaw, Madras Army; Duncan, Trench, Liverpool; Baylis, Birkenhead; Leeper, Robinson, Leeds; S. S. Bartley, Morris, Baltimore, U.S.; Davys, Curgenvin, London; Holden, Glenarm; Martin, Seaton Reid, Drennan, William MacCormac, Cuming, James Moore, Whitaker, S. Browne, R.N.; Fagan, M'Williams, Wales, Stewart, Wheeler, Higginson, Lisburn; Kelso, Lisburn; Gordon, MacCormac; M'Gee; John Moore, Patterson, Browne, Murney, Mulholland, Pirrie, Thompson, Donaghadee; Dill, Dunlop, Holywood; Harkin, Thomas Reade, Johnstone, Porter, and H. S. Ferguson; Messrs. Berry, Pring, and Martin.

The chair was occupied by Dr. Seaton Reid, President of the society.

Dinner having been partaken of,

The Chairman said—Before the more formal business of the evening commences I may state that it is the wish of the council of our society that as far as possible the list of toasts entered on the programme should be adhered to, and the duty of placing the first of these before you now devolves upon myself. Sir James Simpson, guests, and members of the Ulster Medical Society, knowing that I am surrounded by a number of educated gentlemen, all of whom belong to the medical profession, I feel that it would be quite superfluous in me to make many preparatory remarks respecting the toast I have now to place before you, because I am aware that there is no class in the community more competent to appreciate the eminent virtues displayed by the Sover-

eign of these realms than the medical profession, and certainly none who more fully admit the beneficial influence her example has exercised over all classes of the community. Who among us has not heard of the intellectual dignity with which she presides over the deliberations of her Privy Council, of the unceasing anxiety she there exhibits that even-handed justice should be dealt out to all classes and grades of her subjects, of the scrupulous jealousy with which she has guarded the honour and interests of the nation, and, above all, of the unparalleled wisdom she always displayed in the numerous political crises of our country? or need I recall to your recollection how often she has manifested the most intense sympathy for those families into which some sudden calamity or affliction had gained access, whether such was found in the family of the President of a powerful nation or in the humbler cottage of a suffocated miner? Have we not known her on all such occasions manifest the liveliest sympathies of a woman when necessity required it—the generosity of a Queen; or if I ask you to remember what must have been one of the most magnificent sights ever witnessed by the inhabitants of this country, when our Queen did not deem it beneath her dignity to receive in her park her maimed and emaciated soldiers returning to their homes after fighting the battles of their country, and when, addressing some kind words of sympathy to each, she placed, with Queenly grace, around their necks those badges of honour, to become heir-looms in their families, and tell of the deeds of valour they had performed. Now, when such have been the virtues and the graces of our Queen, has she not proved herself worthy to reign over an Empire on which the sun never sets? Gentlemen, I will not insult you by asking you to be loyal to such a Sovereign, because I know right well that there does not exist in the breast of one of you an atom of disloyalty, and I do feel a deep gratification when, on behalf of the medical profession of Ireland, I am able to tell these eminent guests who are here from other parts of this Kingdom that, with the wave of disloyalty which so recently swept over a portion of this island, there was not found associated the name of one single member of the medical profession. (Cheers.) Gentlemen, we were not loyal because we were wealthy, and had property to lose in the conflict, but we were loyal because the virtues of our Queen had enshrined her in our hearts. Knowing all this, I feel certain that, when I ask you to join me in wishing long life and happiness to the illustrious lady who wields the sceptre of these realms, I shall receive in return from you all a righty hearty response. Gentlemen, the toast is, “Her Majesty the Queen.” (Applause.)

The toast having been drunk,

Dr. THOMAS READE proposed “The Army and Navy Medical Departments.”

Staff Surgeon-Major Fennell responded on behalf of the army, and Dr. M'Gee, J.P., on behalf of the navy.

Ulster Medical Society
Session 1867–1868
President James Seaton Reid

Chairman—Gentlemen, the next toast that I have been requested to submit is that of Sir James Simpson, President of the Health Section of the Social Science Congress, to which high office he was elected on account of his great intellectual attainments; and the anxiety he has always shown to promote the happiness of his fellow-men. No one could have heard or read the eloquent and beautiful address he delivered at the Congress yesterday without being convinced, from the masterly manner in which he dealt with the various topics he referred to, that the Society had only honoured itself by placing him in the eminent position he was in. The biographers of all great men almost invariably inform us that their hero had in early life displayed some mental peculiarity, or trait of character, which foreshadowed his future greatness. As I do not know anything of the early life of Sir James Simpson, I am unable to tell if he had shown any of those peculiarities; but, be this as it may, I am certain you will all agree with me when I say, that from the moment he came before the medical world, whether as an author or a teacher, he evinced an originality of thought and invention, associated with the will and the power for the practical application of his discoveries, that placed him at once amongst the most eminent men of his day. It was, no doubt, this originality of his genius that led him to apply chloroform as an anæsthetic, and which placed at the disposal of his professional brethren the most efficient means of relieving pain; thus conferring on mankind one of the greatest boons they had ever received, and clothing himself with imperishable fame. But, not content with the laurels he had thus acquired in the department of science with which he was more immediately connected, his power of invention led him to invade the domain of practical surgery, and to place at the feet of the operative surgeon a means of restraining hæmorrhage superior to any within his reach; for I believe I speak the mind of every impartial surgeon who has tried acupressure, that it is in all respects equal, and some respects superior, to the ligature. Nor did his versatility of genius and originality of thought allow him to remain content with the pre-eminent position thus acquired in both medicine and surgery, but they led him into the field of archæology, and here again his high mental endowments have enabled him to make discoveries that have placed him on an equality with our countryman, Petrie. And, gentlemen, I believe that I speak the mind of every member of the medical profession when I say that, when the annals of medicine for the present century shall have been written, no name shall stand out more prominently on the page of history than that of Sir James Simpson, both for originality of invention and the practical application of his discoveries. But, Sir James, we trust it will be many long years before you become food for the historian; and that you may be long spared that vigour of mind and body which have enabled you, among the toils of a most fatiguing

department of practice, to carry on those researches which have made you a benefactor of mankind. Gentlemen, the toast is, "Sir James Simpson, President of the Health Section of the Social Science Congress." (Loud cheers.)

Sir JAMES SIMPSON was received with loud applause and cheers. He said he was glad he had been induced to come to Belfast to meet the Ulster Medical Society. It was a great thing to grasp the hands of many men who had been his dearest friends, and of other men amongst them—Sir James Murray—whom he had long known, but had never seen till then. It was not to be expected he would make a long speech. He came to Belfast suffering from the effects of a horrible tempest. He had spoken about air and the necessity of it, but he could tell them he had had a great deal too much of it. (Laughter.) Sometimes a doctor got too much of his own medicine, and he had, indeed, got too much of his. It had been said by the chairman that he did not know anything about his early history. They had a Member of Parliament for Edinburgh, Mr. Maclaren, and many years ago, he was almost ashamed to think how many, when he (Sir James Simpson) became a candidate for the chair of midwifery, which he now occupied, he was opposed by Mr. Kennedy, of Dublin; and he could give them his word for it, if he had had a vote he would have given it to Mr. Kennedy, for he deserved it better than he did. (Laughter.) Mr. Maclaren came one day to him (Sir J. Y. Simpson) and asked him had he any certificates as to qualification for the chair. He told him he thought the best certificate would be his early history, and that ten years ago he was driving his own father's breadcart. (Loud applause.) He did not think that discreditable. (Renewed applause.) The chairman had alluded to some of the things he had done; but when he looked back he thought he might have worked at many things better, and many things more important; and he would just say one thing, and that was, that he was sure the gentlemen there would ever find that the study of his profession was the greatest rest possible. (Applause.) He had known very little of their sanitary matters, but he had gained a great deal of information from Dr. Browne's paper, and a great deal from the discussion that followed it. He had heard more of sanitary matters than he ever knew in his life before—(laughter)—a poor person to be president of the section—a scholar, and not a master of the subject. He had learned from the paper that here they executed two men every day by the bad state of their sewers. He had no doubt the day would come when they would not turn all their sewerage into the bay of Belfast. The day is coming when all that filth would be turned into human food. They did not know until they looked at it how much tillage and agriculture would do. He had read of a little very badly-tasted root that grew in Chili, and which still grew there wild upon the mountains, which under cultivation had come to be converted into a building of Irishmen. (Laughter.) It is

literally true; for the potato had become converted into millions of Irishmen who steamed over the country away to the west, to which their aspirations were; and when they thought of that little Peruvian root and what it had done, they might well think that the filth of such towns as Edinburgh and Belfast would yet become the food for thousands and millions more. He thanked the chairman for the manner in which he proposed the toast. He had great pleasure in meeting the members of that society, and he would remember that night as one of the bright and white nights of his life. (Applause.)

Dr. M'GEE, in a brief speech, gave the toast of "The Health of the Medical Coroners," coupled with the names of Drs. Lankester and Dill.

Dr. Lankester rose, and was received with loud applause. It gave him great pleasure to be present that night to meet the members of the Ulster Medical Society. He was glad the holiday he had taken had brought him to Belfast, and brought him to meet his friends that evening, and he was much obliged for the kind manner in which they had associated his name with the toast of "The Medical Coroners." This subject was one of great importance. None but medical men should occupy the office of coroner, and he believed they were indebted to Mr. Buckley, the editor of the *Lancet*, for having first advocated this matter. He was the first man who devoted himself to showing that medical men were the men for the office, and there could be no doubt of the truth of the statement at all. The great mass of evidence brought before coroners' courts was of such a kind as could only be understood by men instructed in medical science, and in which justice must be defeated where the coroner has no knowledge of the evidence. He remembered one of his friends told him if he carried out the principle that coroners were to be instructed in medical knowledge, it would just be the same with regard to the Judge—he ought to be medical also. Well, he (Dr. Lankester) would not hesitate to pick up the gauntlet thus thrown down, and say it was most important that the Judge should be instructed in the science of medicine. He thought the education of the Judges was deficient; and, until they got what was called a medical education, they were not properly qualified for the bench. It was impossible for a coroner properly to discharge the duties of his office without being a medical man, and their present relation to the Coroner's Court was not so much that the medical profession should be appointed coroners as that the general community should know more about the natural laws which govern the world. The education of our lawyers is in mathematics, Greek, and Latin, but these give no idea as to the cause of death. The question was coming up very strongly at the present time whether or not the coroner should be educated in those natural laws by which our lives are governed. The medical professors should band themselves together more strongly than they did, and let it be seen that it was the future

well-being of mankind they were considering. The fact was that in many cases a coroner who did not possess medical knowledge was often misled, and a great amount of crime had been passed by the incompetency of the ordinary legal coroner to weigh the value of the medical evidence presented. Dr. Lankester very urgently demanded that this question should be thoroughly ventilated, as it was one of the greatest importance, and sat down amid loud applause.

Dr. Dill having spoken, Dr. Browne, R.N., proposed the toast of "Sanitary Science," coupling with it the names of Dr. Mapother, Dublin, and Dr. Morris, Baltimore, to which those gentlemen responded.

Dr. MACCORMAC then gave the "Humane treatment of the insane and imbecile," to which were coupled the names of Dr. Skae and Dr. Kidd.

Dr. KIDD, Editor of the *Dublin Quarterly Journal* having acknowledged the toast,

Sir J. Y. SIMPSON proposed "The health of the President, Dr. Seaton Reid."

The President having responded, the proceedings were brought to a conclusion.

Fifth Meeting, 5th October, 1867

Present, Dr. Thomas Reade in the chair, Professor Cuming, Drs. Stewart, William MacCormac, H. Brown, Porter, H. S. Purdon, McWilliam, John Moore, Messrs. Martin and Newett.

Dr. H. Brown introduced a patient labouring under progressive locomotor ataxy and read notes of the case.

Paper:¹ Mr. M. J., aged twenty-eight, single, well-made, and about six feet in height, consulted me in August last. After a very careful examination, I considered him labouring under locomotor ataxy, or Duchenne's disease; but, as I had never seen a case before, I thought it advisable to consult some of my medical friends, and he was seen by Dr. W. MacCormac and Professor Cuming, both of whom considered the case one of locomotor ataxy. The symptoms first began about ten years ago; but for the last four years they have greatly increased, during which time he has been under treatment (at one time or another) of various kinds, without receiving benefit.

His attention was directed to his feet at a very early stage of the affection, and he found that in walking, a constant watch was absolutely necessary to enable him to progress with any degree of satisfaction. The habit of walking with his head in a downward direction he could not account for; but he was certain that up till his eighteenth year he had not noticed anything peculiar in his gait, and was not in the habit of "hanging his head." At present, when walking, he resembles a person under the influence of liquor, throwing his feet out without

¹ [*Dublin Quarterly Journal of Medical Science*, 1868, v45, p480.]

any precision, and they fall heavily upon the ground. His feet, even to himself, seem to fall “all of a piece,” and when they come in contact with the ground a sensation is conveyed to him, so that he imagines it possesses no firmness, and he is obliged to use a staff to prevent himself from falling. Under no circumstances could he walk in a straight line.

In damp weather every bone seems dislocated, and the muscles of the legs are much more beyond control than in dry bracing weather. He dreads this relaxation much, for it is with the utmost difficulty he can at all progress. The limbs seem to be well nourished. No diminution in the sensibility of the cutaneous surface can be observed. The points of compasses or other sharp-pointed instrument, can be perceived with exactness; and I took care that the eyes were obscured during this examination. He can flex and extend the legs with great force. When the leg was extended, neither Professor Cuming nor I could flex it. When seated and requested to raise a leg into the horizontal position, he can do so without any assistance; but his eyes are steadily fixed upon the limb during this movement. He cannot stand upon one leg, nor can he stand when his feet are close together, without the aid of a staff, and then only with difficulty. He cannot bring the feet into close approximation without considerable shuffling; and, if he be requested to close the eyes when standing with his feet together, he is seized with a sensation of dread lest he fall, and he opens the eyes after momentary closure with delight at finding himself still standing upon terra firma.

The upper extremities are well nourished. For some time he has been very much troubled with “a burning” of the hands, which causes great annoyance; and, as he is a book-keeper, he requires to bathe the hands frequently in cold water to ease this painful sensation, which is always attended with profuse sweating. He can write with his wonted facility, except in the morning, when the right hand is rather tremulous, but this usually disappears in half an hour or an hour after commencing business. There is no paralysis of the upper extremity. In order to test his strength I got him to lift a bale of tow—weighing one hundred and a quarter—and this he could have carried upon his back, but for a tendency to fall which he experienced, owing to the want of control over his lower members. He told me he could lift even more than the above weight, and that his strength in this respect was as good as could be.

In the lumbar region an acute burning pain is sometimes felt, which often continues for an indefinite time, and a painful spot can frequently be pointed out, but not always. Percussion, however, causes not the slightest pain; and the spinous processes may be pressed upon without eliciting pain. When pressing the lumbar spines on one occasion, however, pain was felt, and he expressed it—as if burned with a heated sharp-pointed iron.

This is the region of greatest weakness, and he is obliged to wear a bandage and stays to afford support, else he could not walk. To use his own words—“without the stays he would fall in two.”

Over the frontal region a dull heavy pain is almost a constant companion, and, at times, confusion of ideas accompanies it. Noise in the head troubles him very much, and is greatest after rising in the morning. This noise he compares to water heard falling from a considerable distance. In order to remove a feeling of stupor he is obliged to wash his face in the coldest water obtainable, every morning, at least three or four times, and this process is repeated several times during the course of the day.

When exposed, during the transaction of business, to the open air, and then confined to office work, the stupor becomes most unpleasant, and ablution is the only relief he can obtain. There is constant singing in the ears, and the sense of hearing has become blunted of late. The pupils contract perfectly upon the stimulus of light; they are larger than usual, but there is no impairment of vision, nor does he complain of visionary spectra.

The senses of taste and smell are unaffected.

When spoken to in a loud or commanding manner he loses all control; and he has frequently been nearly run over on the street from his inability to move when shouted at. At night, it is with great difficulty he can cross from one side of the street to the other, and his gait is much more unsteady, for an obvious reason. His digestion is excellent, and the bowels are never confined. There is no paralysis of the rectum. The bladder possesses its tonicity, and the urine is voided with ease, but he requires to wait a little before the process of emptying commences. This process requires no straining, however.

Sleep is disturbed by frightful dreams, and he invariably awakes at three o'clock in the morning. Seminal emissions occur at least three or four times in the week, and exhaustion is very great after these. There is no incontinence of urine at night. I have inquired whether he has had any of the shooting pains which “come on and go off with the rapidity of lightning, or of the electric spark,” and find at no time have they been observed. I have observed his articulation, and consider it slightly muffled of late, but it is distinct. He confesses it is not so good as it formerly was.

He has never been guilty of excess of any kind.

His father is alive, and has attained the age of sixty-seven. His mother died a short time ago at the age of sixty-two. For the last two months of her life she was unconscious, or nearly so; and is supposed to have died of some heart affection. This is all the information I can obtain in reference to her death. She was very healthy previously to an attack of rheumatism, from which she never got quite well. His brother, who is a few years younger than the patient, is a healthy young man.

As regards treatment, various remedies have been employed from time to time, by others and by myself, without any appreciable benefit. He has taken strychnia, phosphorus, iron in various forms, iodide of potassium, and tonics in every shape and form, without any good result. Liniment of iodine was applied to his back previously to consulting me, electricity, and no end of other means proving quite impotent to remove, or even slightly benefit his condition. His affection was considered to be paralytic by some who saw him early, and others thought it was inflammation of the spinal cord or its membranes.

More benefit has been obtained from cod liver oil, and a good wholesome diet, with a liberal use of sweet milk, than from all other means combined. I advised nightly ablutions of the genitals with cold water, and great good has resulted from this practice.

Under the use of some lauded remedies the patient lost ground; iodide of potassium increased the debility, although he got only a grain and a half twice daily. An occasional bottle of porter, with the generous diet, have caused an increase in his weight of several pounds within a very short time.

At present (19th March, 1868,) the condition of the patient is much the same as when seen by the members of the Ulster Medical Society in October. He is getting a pair of spring stays made, and he hopes to be able to walk with greater ease. The generous diet is still continued, and the patient considers his condition "at a stand-still." I can observe no change myself; but he is decidedly stouter than when I first examined him.

—October 16, 1867.

Dr. McWilliam read the notes of an unusual case of paralysis of the intercostal muscles.

Dr. Porter read remarks on the termination of a case of phagedænic chancre, notes of which were read before the Society at a former meeting.¹

Paper:² When criticising the former portion of my paper on this case, some members of the society expressed the opinion that the absence of any cutaneous eruption rather disproved a connection to exist between the morbid conditions of the eye and the primary sore.

Mr. Henry Lee (in his letter to the editor of the MEDICAL PRESS AND CIRCULAR, of April 17th, 1867), attributed the eye affections to debility of the system. On the 6th of last March, the missing link was supplied by the development of a tuberculous eruption, disseminate in character, and located as follows:—Three spots on the forehead, three under the hair of the head, one on the chest, a number between the shoulders, one behind the right thigh, and two in a semi-ulcerated condition, to the left side of the nose; there were also four irregular spots on the chin. Some of these patches were sore,

¹ [See page 1070.]

² [Medical Press and Circular, 1867, October 30, p401.]

others of them intensely itchy. His ears were very painful, and discharging a scanty quantity of serum; both tonsils were deeply ulcerated; his tongue was slightly furred, but his appetite was good, and his bowels were regular. The throat was thoroughly cauterized with the stick nitrate of silver. He was still taking cod liver oil. Recommended a renewal of the corrosive sublimate (the use of which had been suspended), also twenty drops of tr. of steel, to be taken three times daily, and occasionally a full dose of Dover's powder at night, to be followed by Gregory's mixture next morning.

On the 10th of March the spots had begun to wither up; their colour also had altered from a bright-red to a copper hue. No fresh ones had appeared. From the left ear a black fœtid discharge, and from his right ear a white starchy matter oozed freely; the ulcers on his tonsils were less unhealthy looking, but were again cauterized, and ten grains of chlorate of potass was ordered to be taken each morning before breakfast.

On the 10th of March no new spots had appeared, and the old crop seemed to be dying away. His throat was considerably better; his complexion was very dusky, and his spirits were dull. He suffered a good deal by his ears, the discharge from which was much lessened, and frequently became concreted. On May the 10th, Dr. W. MacCormac kindly accompanied me to visit the patient, at which time his general appearance was better. Dr. MacCormac then agreed with me in considering the case one of true constitutional syphilis. The eruption on this occasion had died away to a considerable extent, but slight ulceration of the tonsils still remained. His ears were much better. Some of the concatenating glands were enlarged, as they had been for a few weeks previously.

Since then I have seen the subject of this paper, and am happy to state not a trace of the old disease remains, and that he now enjoys perfect health.

Dr. William MacCormac exhibited parts removed in a case of fracture of the spine.

R. Stewart, Chairman
22nd November, 1867

516¹ Notice of meeting on 1st November 1867

President.

Dr. Seaton Reid.

Ex-President.

Dr. Drennan.

Vice-Presidents.

Dr. Thomas Reade.

Dr. Kelso, Lisburn.

Dr. James W. T. Smith.

Members of Council.

Dr. Patterson.

Dr. Whitaker.

Dr. Stewart.

Dr. Bryce Smyth.

Dr. W. Mac Cormac.

Dr. H. S. Purdon.

¹ [Also Item 501.]

Ulster Medical Society
Session 1867–1868
President James Seaton Reid

Treasurer.

Dr. Cuming.

Secretary.

Dr. John Moore.

The Sixth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 1st of November, at Half-past Seven o'clock.

Business.

Pathological Specimen

Mr. H. M. Johnston will exhibit a Specimen of Ulceration of Cartilages of Knee Joint, and one illustrating Intra-capsular Fracture of Neck of Femur.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 30th October, 1867.

Sixth Meeting, 1st November, 1867

Dr. Samuel Browne in the chair, members present, Drs. H. Brown, Fagan, Porter and John Moore.

In absence of Mr. H. M. Johnston who was to have exhibited a specimen of ulceration of cartilage etc., no business was transacted.

502 Notice of meeting on 22nd November 1867

The Seventh Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 22nd instant, at Half-past Seven o'clock.

Business.

Members to be Proposed.

Dr. Hill and Dr. David Johnston.

Pathological Specimen

Dr. James Moore will exhibit a Penis which he amputated.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order, John Moore, M.D., Secretary.

Belfast, 21st November, 1867.

Seventh Meeting, 22nd November, 1867

Dr. Stewart in the chair, Drs. Samuel Browne, Dill, Whitaker, H. Brown, and John Moore.

Dr. S. Browne read a communication from Dr. Curgenven Secretary of a newly formed Society for the Prevention of Venereal Diseases and requesting the assistance and cooperation of the Ulster Medical Society. The communication was referred to the Council.

Dr. Hill was proposed by Dr. Whitaker and seconded by Dr. Dill and Dr. David Johnston was proposed by Dr. Dill and seconded by Dr. Whitaker.

503 Notice of meeting on 6th December 1867

The Eighth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 6th instant, at Half-past Seven o'clock.

Business.

Members to be Balloted for.

Dr. Hill and Dr. David Johnston.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 4th December, 1867.

Eighth Meeting, Friday 6th December, 1867

Dr. Patterson in the chair, members present Professor Cuming, Drs. Stewart, James Moore and John Moore.

Drs. Hill and David Johnston having been duly proposed and seconded at former meeting of Society were balloted for and unanimously elected members of the Society. The Secretary was directed to receive in future the weekly periodicals direct and issue them without delay to the members of the Society.

James Patterson, Chairman

504 Notice of meeting on 20th December 1867

The Ninth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 20th instant, at Half-past Seven o'clock.

Business.

Dr. James Moore will exhibit a Cancerous Penis which he amputated.

Dr. James Moore will give an account of his recent visit to Arcachon, Gironde, France, a new favourite resort for invalids suffering from chest affections.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 18th December, 1867.

Ninth Meeting, Friday 20th December, 1867

Dr. Patterson in the chair. Members present, Drs. Stewart, James Moore, H. Brown, Fagan, Wales.

Dr. James Moore exhibited a cancerous penis which he had amputated and narrated the history of the case.

He also gave an interesting account of a recent visit to Arcachon, Gironde, France, a new favourite resort for invalids suffering from chest affections.

505 Notice of meeting on 3rd January 1868

The Tenth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 3rd instant, at Half-past Seven o'clock.

Business.

Recommendation of Council.

That the Transactions of the Society be published in The Dublin Quarterly Journal of Medicine, and that the papers intended for publication be furnished to the Secretary.

Pathological Specimens.

Dr. Drennan will exhibit Kidneys with diseased Supra-Renal Capsules, and read notes of case of simulate Abdominal Aneurism.

Professor Cuming will read notes of a remarkable case of Empyema.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 1st January, 1868.

Tenth Meeting, 3rd January, 1868

The President in the chair. Members present, Professor Cuming, Drs. Stewart, Wales, David Johnston, Hill, Fagan, James Moore, Messrs. Newett, Patterson and John Moore.

Dr. Drennan sent for exhibition kidneys with diseased super-renal capsules:

Paper:¹ Dr. Cuming exhibited the supra-renal capsules of a patient who had been in hospital under the care of Dr. Drennan. The capsules were greatly enlarged, and contained large cheesy masses, having the characters of tubercle. The lymphatic glands in the neighbourhood were also tuberculous. There was no discolouration of the skin or of the mucous membranes. The patient had suffered principally from abdominal pain and gastric irritability.

Dr. James Moore exhibited a fibrous tumour which he had removed from a patient's breast.

Professor Cuming read notes of a remarkable case of empyema.

Paper:² The following case is, I think, of sufficient interest, in a diagnostic point of view, to make it desirable that it should be recorded.³

Neal Kennedy, aged thirty-five, unmarried, labourer, was admitted into the General Hospital July 30th, 1867.

History.—Several members of his family died of tubercular diseases. Seven years ago he had been a patient in this hospital, the only record of his case to be found being the name of the disease for which he was admitted—"Hydro-pneumothorax"—and the period during which he was an inmate—namely, fourteen days. From this illness he states that he completely recovered. Two years ago he passed through an attack of typhus fever, for which he was treated in the Union Hospital of this town. With these exceptions his health has been always good; habits regular and temperate. He is a well-built man, pale, slightly bald, with an intelligent countenance, and rather prominent eyes.

About six months ago he began to suffer from pain in the left side, which he describes as having been of a catching character, lie continued to be able to work for some months after the commencement of the pain. His strength and appetite, however, gradually failed, and his breathing became oppressed. He placed himself under medical treatment, and was blistered and purged without any benefit.

At present he complains principally of weakness; he has some diarrhoea; no pain in side; very little cough, and the dyspnea is not at all considerable. His appetite is tolerably good; decubitus on back or left side; he sleeps pretty well.

Physical examination.—The left side of the thorax is observed to be dilated, its intercostal depressions ef-

¹ [Dublin Quarterly Journal of Medical Science, 1868, v45, p483.]

² [Dublin Quarterly Journal of Medical Science, 1868, v45, p44.]

³ Reported by Mr. Robert S. Hudson, clinical clerk.

faced anteriorly, and no respiratory movements visible. A soft, painless, inelastic tumour is observed external to the left nipple; its diameter at the base is about two inches, and it covers portions of the seventh, eighth, and ninth ribs; the skin covering the tumour is not discoloured, nor is there any pulsation in it.

The impulse of the heart is visible on the right side, below, and rather external to the nipple. On palpation no vocal fremitus is to be felt in the left side, except close to the spine posteriorly. The circumference of the left side, on the level of a line passing from the spinous process of the seventh dorsal vertebra over the nipple, is $21\frac{1}{2}$ inches; that of the right 19 inches.

On percussion absolute dulness is found to extend over the entire left side, and for about an inch beyond right margin of sternum. No respiratory sounds are audible, except in the neighbourhood of the spine; no vocal resonance. Respiration puerile on right side. There is distinct bulging in the epigastric and hypochondriac regions, owing evidently to displacement downwards of the diaphragm and of some of the abdominal viscera. Some tenderness on pressure is complained of in the left hypochondrium, where the depressed and resistant diaphragm can be readily recognized by the finger.

Pulse 72; in the right wrist tolerably full and soft, in the left very small—a fact to which my attention was first drawn by one of the students who surrounded the bed. A similar difference, but not so marked, was observed in the carotids. No murmur with the action of the heart; sounds normal. Pupils equal.

After consultation it was determined that the thorax should be tapped, as there could be no doubt of the existence of pus in the cavity of the pleura. Before the period arranged for the operation, however, he began to bring up by coughing considerable quantities of pus, and I hoped that in this way the entire contents of the pleural sac might be evacuated. During two days and nights the matter continued to be expectorated; the entire quantity got rid of in this way amounting to fifty-six fluid ounces. The impulse of the heart was now visible at a point higher than before by about an intercostal space, and the circumference of the left side had diminished by three-quarters of an inch, being now $20\frac{3}{4}$ inches. The amount of the expectoration was, however, diminishing a good deal, and the constant efforts to bring it up had become very distressing to the patient. He was totally unable, from this cause, to lie down or get any sleep. The pulse rose to 116, the difference in the two sides being still considerable; but it was thought rather less marked than it had been previously, and an inflammatory flush had appeared in the left hypochondrium, where tenderness had been previously noticed on pressure, pointing to the probable danger of perforation of the diaphragm in that situation. Under these circumstances I thought it would be unwise to delay any longer the puncture of the thorax.

The operation was performed by my friend and colleague, Dr. William MacCormac, the opening being made through the tumour and in the eighth intercostal space. At the time of the operation, and during the two subsequent days, 173 fluid ounces of good pus, devoid of odour, flowed from the opening. The operation was followed by considerable relief of the general symptoms; the patient was able to lie down and get some sleep. The intercostal depressions became now manifest; the heart passed over to the left of the sternum; the left radial and carotid pulses acquired fulness, and by the end of the third day no difference could be any longer observed in them. Indeed, more than one of the various medical men who had kindly examined the patient with me at different times, before the paracentesis, and while the inequality existed, on being asked to compare the pulses in the two wrists, were inclined to consider that the left was now rather the fuller and stronger. The discharge gradually diminished to about two ounces daily; the appetite and strength improved rapidly.

Without entering into details of the progressive changes which ensued, I may now give an account of the physical examination of the chest a fortnight after the chest had been tapped. The girth of both sides had diminished—that of the right side being now $18\frac{1}{4}$ inches, that of the left $18\frac{5}{8}$ inches. Taking the level of a line passing from the spinous process of the eighth dorsal vertebra through a point an inch below the nipple, we find that above this line the left side is resonant on percussion—duller than the right—but still moderately resonant. Within the same space vocal resonance and fremitus are distinctly recognizable, and the sounds of respiration are audible, being somewhat weaker and more harsh than those of the opposite side. There is no trace of r le of any kind, nor is there any friction sound.

Below the line mentioned vocal resonance and fremitus are altogether absent; 110 respiratory sound whatever is audible. On percussion we find amphoric resonance in front when the patient lies on his back, and some dulness at the most dependent part posteriorly. The situation of the resonance and dulness changes with any change in the position of the patient, but does not reach a higher level than that of the line above mentioned. Pus flows pretty freely from the wound when the patient leans well forward, and a probe introduced through the wound can be moved freely in a large cavity. It was now evident that the lung had expanded considerably, but not sufficiently to fill the entire side, and that it had become adherent to the thoracic parietes, leaving between its base and the superior surface of the diaphragm a loculus filled with air and matter. The heart's sounds were quite normal, and unaccompanied by any echo or splashing.

With the diminished circumference of the upper part of the thorax, the bulging at and below the base became more noticeable, and a curious phenomenon

became observable—namely, a depression of the prominent portion of the epigastrium and hypochondria, during inspiration, and an elevation during expiration; both these movements being the opposite of those observed during health. This depression was more evident when a somewhat forcible inspiration was made, and was much more marked on the left side, but even on the right side it was distinctly observable both by inspection and palpation. The amount of discharge was now about one fluid ounce daily. There was scarcely any cough; respiration free; appetite good, and strength fair. The patient remained up the entire day, and walked a good deal about the ward in which he was. From this period until he left hospital there was little change in the symptoms. The bulging diminished gradually, but the abnormal condition of the respiratory movements continued, although no longer recognizable, except when the hand was placed on the surface of the epigastrium or hypochondria. He continued to improve steadily, with the exception of some inflammation of the lymphatics of the right leg, which yielded readily to rest, and the application of the flannel bandage recommended by Sir Dominic Corrigan. He was able to remain some hours daily out of doors, and left hospital at his own request at the end of September.

About the end of October I visited him, at his own request, at his mother's house, in a filthy little street in one of the oldest and most neglected parts of the town. I found that he had been for some time getting worse; he had not been able to get nutritive food, and he had ceased to take the cod-liver oil which had been prescribed for him. The discharge had increased and become very offensive in smell, and diarrhoea had set in, with a good deal of irritability of stomach. There was scarcely any cough; no expectoration; and the condition of the chest was very little changed. I advised him to go to hospital again, which he wished to do. However, about a fortnight after I learned that he was dead.

I have not entered into any account of the treatment, as there was nothing worthy of remark in the measures employed. Tonics—a moderate amount of stimulants and cod-liver oil forming the staple of the treatment.

Remarks.—All observers agree as to the fact of the pulse remaining unaffected in cases of empyema. A case by Larrey, in which extreme feebleness of the pulse in the large arteries coincided with cardiac displacement, is quoted by Walshe,¹ who is not inclined to consider that there was any mutual dependence between the two circumstances. Murmurs with the sounds of the heart have been observed, probably dependent on torsion of the aorta, in cases of great cardiac displacement, and an instance² is given of empyema of the left side, in which an aortic bruit, the result no doubt of pressure, was audible from the last rib upwards along

the left side of the spine for about five inches. I am not aware, however, of any case being on record in which a difference in the pulses was noticed. In a recent and excellent work¹ on diseases of the lungs, the equality of the radial pulses is referred to as a diagnostic mark which may be relied on in cases of doubt as excluding the idea of empyema. Had the empyema been a pulsating one, as in the well-known cases reported by Dr. M'Donnell,² the diagnosis might have become very embarrassing. It would be easy to suggest modes by which this phenomenon may be caused. My own opinion inclines towards seeking for the explanation in some narrowing of the arteries by torsion or otherwise, inasmuch as the absence of any evidence of venous congestion puts the idea of its having been caused by direct pressure of the fluid out of the question. Whatever be the explanation, however, the possibility of the existence of an inequality of the radial pulses in a case of empyema, the inequality disappearing after the evacuation of the fluid, is a fact of some clinical importance.

The alteration in shape and movements observed at the base of the thorax and at the upper part of the abdomen evidently depended on the condition of the diaphragm. The paralysed and probably degenerated condition of this muscle, caused by the long-continued pressure, and probably, also, by the effect of the inflamed state of the pleura, prevented the action which is normally exerted on the base of the thorax by the fibres which arise from the ensiform cartilage, and from the cartilages of the lower ribs—an action which is antagonistic to any forward movement of that region. Besides, the depression of the diaphragm, as well as of the upper abdominal viscera in contact with it, owing to the great mechanical pressure exerted by the superincumbent mass of fluid, would tend powerfully in the same direction. It was very remarkable, however, that the bulging should have continued after the removal of the great bulk of the fluid. This can only, I think, be accounted for by supposing that the diaphragm had contracted some adhesions with the parts with which it had been brought into contact during the continuance of the pressure. Duchenne,³ criticising Dr. Stokes' observations⁴ on the condition of the diaphragm in some cases of empyema, observes, with justice, that paralysis of this muscle must, of necessity, be followed by an increase of its natural convexity, and by its becoming more elevated in the cavity of the thorax, owing to the action of the abdominal muscles. Some cause must accordingly have been in operation to retain the muscle in its anomalous position.

The explanation of the reversal of the usual respiratory movements is also to be looked for in the passive

condition of the diaphragm, allowing it to yield to the action of atmospheric pressure when a partial vacuum was formed in the chest by the action of the other respiratory muscles during inspiration, and the elevation during expiration to the pressure exerted by the lungs then acted on by the elasticity of the thoracic parietes.

Duchenne¹ suggests that valuable indications may be drawn in cases of empyema from a deficiency of isochronism in the movements of the thoracic and abdominal walls during inspiration and expiration, and gives some cases of empyema observed by Racle and others, as well as by himself, in which the hands placed one on each hypochondrium were moved in contrary directions during respiration—that placed on the sound side being elevated during inspiration and depressed during expiration, while that placed on the side where copious effusion existed was moved in the contrary direction. When this phenomenon is observed, he thinks that the diagnosis of paralysis of one-half of the diaphragm may be made, and that a probability is established, as had, indeed, been suggested by Dr. Stokes, of the effusion being the result of an acute inflammatory process, and not a simple hydrothorax. In this case Duchenne's sign did not exist, the action of the diaphragm—although the empyema was single—being null on both sides. At the same time some weight must be attached to the great amount of malposition of the diaphragm, altering completely the direction of its muscular fibres.

James Patterson, Chairman

506 Notice of meeting on 17th January 1868
The Eleventh Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 17th instant, at Half-past Seven o'clock.

Business.

Dr. William Mac Cormac will give an account of a case of Popliteal Aneurism.

Dr. John Moore will read notes of Complicated Cases of Midwifery.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 15th January, 1868.

Eleventh Meeting, 17th January, 1868

Dr. Patterson in the chair, Drs. Stewart, James Moore, McMurtry, Fagan, William MacCormac, Wales and John Moore.

Dr. William MacCormac gave an account of a case of popliteal aneurism treated by compression:

Paper:¹ Daniel Dobbin, a man twenty-seven years of age, pale and thin, of a lymphatic temperament and peevish disposition, was admitted to my wards in the General Hospital, on Sept. 25, 1867. His occupation is to drive a spring-cart, and he states that four months ago he fell off the cart, striking the step in his descent. He felt his leg very painful for some time, but the limb afterwards perfectly recovered.

About six or seven weeks before coming to hospital he noticed a feeling of stiffness in the right ham, followed by the appearance of a small tumour as large as a bean, which rapidly increased in size.

On admission we found an aneurism filling up the right popliteal space, and fully as large as a medium-sized orange. There was a bruit, and strong distensile pulsation, which could be readily controlled by pressure upon the artery in the groin, and whilst the pressure was kept up the sac could be emptied almost completely. The leg was œdematous, the pulse 60, and rather weak, the heart sounds are natural, and the tongue is quite clean.

The treatment at first consisted in gradual compression, and then an attempt at complete, which only proved partially successful.

Carte's compressor was first employed, but the restlessness and fretful disposition of the patient continually disarranged the apparatus, and I found Signoroni's tourniquet more efficient and more manageable, as well as more readily borne by the patient.

On the 7th October, twelve days after admission, compression having been maintained more or less perfectly for about ten hours each day, it is reported that, although perhaps somewhat firmer and smaller, the tumour is but very slightly altered since admission, and for the last five days scarcely any change has taken place. I therefore determined to try the method of complete compression, and effect, if possible, a rapid cure. I ascertained that a pressure of four pounds readily controlled the femoral, and devised the following arrangement, which was simple and efficacious. I suspended directly over the patient's groin a short round bar of iron, 8 lbs. weight, by means of a cord attached to the ceiling, and into this cord was inserted a piece of India-rubber, so arranged as to reduce the pressure of the iron to four pounds, and to steady the apparatus at the same time. A round button, about an inch in diameter, of polished mahogany, was attached to the end of the bar next the skin. All that was necessary was to lay this upon the artery, just below the pubis, and with hardly

¹ Loc. cit., p. 728, et seq.

¹ [Dublin Quarterly Journal of Medical Science, 1868, v45, p484.]

any effort of attention the pulsation in the tumour could be kept completely and absolutely arrested. As it was hopeless to expect a patient such as mine to stand the pain, and exercise the needful restraint for any length of time, I was compelled to keep him slightly under the influence of chloroform during the whole period. At a quarter before five, then on the 7th, the pressure was commenced and maintained perfectly for five hours. A few jets of blood, however, in spite of our efforts, occasionally passed, in consequence of the man's struggles. The pressure was then removed for a few moments to examine the condition of the tumour, when it was still found beating. During all this time Richardson's ether spray was directed at intervals on the tumour for about twenty minutes at a time, thoroughly freezing the skin over it. This was frequently repeated, until it was deemed no longer safe, as vesication, accompanied by considerable congestion of the part, took place. The compression was resumed, with the addition of forcible flexion of the knee.

After seven hours' trial of these combined methods, the tumour still pulsated, but much less strongly, and no pulsation whatever could be detected in the superficial femoral. For eleven hours, in short, almost complete compression was kept up. The tumour, however, still pulsated, but not forcibly. The collateral circulation has sprung up, and the attempt had now to be abandoned.

The next day, the 9th, a very faint pulsation could be felt in the femoral. The pulsation in the tumour is very strong, but it feels much firmer.

On the 13th compression of the common femoral was kept up for about twelve hours by Signoroni's tourniquet, and on removal no pulsation was to be felt in the aneurism, nor did it return for eleven hours. Compression was then re-commenced, and maintained as effectively as possible until the 17th, on which day it was kept up from 8.30 a.m. till 9 p.m. On removing the compressor no pulsation whatever could be felt for one minute, and then it returned faintly. On the 21st the pressure was again applied from 9 a.m., till 5 p.m. On removal the aneurism still faintly pulsated, but during the night the pulsation suddenly and finally ceased, and there was no return so long as he remained in hospital. He discharged himself on the 9th December, and the tumour was then becoming gradually absorbed.

Several cases have been recently published by Drs. Mapother of Dublin, Murray of Newcastle, Vanzetti of Padua, and others, showing the advantages of completely arresting the current of blood through the sac in the treatment of aneurism. The treatment of aneurism by compression, a triumph which we owe to the Dublin School of Surgery, has hitherto been based upon the theory that successive layers of fibrine were deposited in the sac, and that to facilitate the cure a certain diminished current of blood must be allowed to pass through the aneurism. If the views now put forward be correct the obliteration of an aneurism is obtained by

the clotting of the blood contained in it, and its subsequent contraction and organization, procured by complete occlusion of the current, and arrest of all movement in the aneurismal sac, for a longer or shorter period of time. In one case mentioned by Dr. Mapother an ilio-femoral sac was obliterated after pressure for four hours and a half on the common iliac, combined with distal pressure on the superficial femoral. In another case of popliteal aneurism pressure on the femoral proved successful after nine and a half hours. At Newcastle an aneurism of the abdominal aorta underwent the process of consolidation in three quarters of an hour, while in another case some twenty minutes are stated to have effected complete cure. The cases reported by Dr. Vanzetti of Padua are, if possible, more striking. They are a traumatic aneurism of the palmar arch cured in thirty minutes, and an aneurism of the femoral cured in less than ten hours.

This method of treatment seems little short of a revolution of that generally accepted, and so indeed it is. In connexion with this matter I read, with great interest and pleasure, some remarks made by my friend Dr. Geoghegan at the late meeting of the British Medical Association in Dublin. He said he had been extremely intimate with Dr. Bellingham, and had seen nearly all that surgeon's cases treated by compression, and for a long series of years had strenuously contended against the principle that the true mode of curing aneurism consists in the mere diminution of the current of blood flowing through the sac. In the discussion which then took place Mr. Ernest Hart, the author of the article "Aneurism" in Holme's Surgery, stated "that he felt convinced that this method of rapid cure by complete compression was destined to become generally adopted as the mode of treatment, par excellence, of surgical aneurism, and that it was almost as great an improvement upon the slow method of treatment as compression itself was upon the method of the ligature."

In the case just narrated I believe the plan of continuous and complete compression would probably have proved immediately successful had it been more efficiently applied. We had, however, in our patient a very unmanageable person, who resisted our efforts in place of co-operating with them, and in his struggles from time to time a small jet of blood must have gained admission. The only hope of speedy and complete success is in the thorough stoppage of the flow of blood to the aneurismal sac. As it was, I believe a partial clot formed, and this, though insufficient at the time permanently to fill up the sac, proved adequate after the lapse of some days, and was the cause of the sudden cessation on the 21st. I believe the very complete manner in which the collateral circulation was established also aided, in a large degree, to protract the cure, as by that means blood was freely supplied to the sac by the distal extremity of the vessel. No direct pressure could prevent this, owing to the situation of the aneurism fill-

ing the popliteal space, and forcible flexion could not be maintained sufficiently long to effect the same object. I should, therefore, in giving this method another trial, effect if possible compression on the efferent vessel, and if that were impracticable, try, in any case, to procure occlusion of the sac without preliminary partial compression, and without affording time for the collateral circulation to supply the sac with blood. The temporary obliteration of the superficial femoral vessel, which never again became restored in size, is an interesting feature in the case. I should mention that the application of the ether spray, which was kept up for a lengthened period each time, seemed to have no other effect than the production of a troublesome superficial slough, which left behind it an ulcer very difficult to heal.

Since writing these remarks I have read a paper by Mr. Samuel A. Cusack, published in the Dublin Quarterly Journal for November, 1859, in which he describes an instrument of simple construction for applying graduated pressure by means of weights to the artery. He mentions that in the first case in which he tried it a cure of a case of popliteal aneurism was effected in twenty-six and a half hours. Although it is not mentioned as such, it is probable that in this instance we find an early example of the effects of complete compression.—January 17, 1868.

Dr. John Moore read the notes of three cases of labour followed by hæmorrhage and two placenta prævia.

507 Notice of meeting on 31st January 1868
The Twelfth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 31st instant, at Half-past Seven o'clock.

Business.

Pathological Specimens.

Professor Cuming will exhibit two specimens of Cardiac Disease, and give an account of a Case presenting some features of Clinical interest.

Mr. H. M. Johnston will exhibit a Gangrenous Leg which he amputated.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 29th January, 1868.

Twelfth Meeting, 31st January, 1868

The President in the chair. Members present, Drs. William MacCormac, Fagan, Wales, McMurtry, Thomas Reade and Johnston, and Mr. H. M. Johnston.

Professor Cuming exhibited two cases of cardiac disease and gave an account of a case presenting some features of clinical interest.

Paper:¹ On Mitral Regurgitation not arising from Organic Disease—The possibility of the occurrence of regurgitation, through the mitral valve, independently of organic disease of any portion of the heart, is a question of great pathological and practical interest. The recognition of the characteristic murmur of mitral regurgitation is generally, and, no doubt, in the great majority of instances, rightly regarded as indicative of serious organic disease. There is reason to believe, however, that inorganic or functional murmurs are of more frequent occurrence than has been hitherto supposed. Functional disturbance of the heart, being usually a remediable affection, there is rarely an opportunity for examining the state of the valve, except in cases in which organic disease has existed. Various observers have, however, been struck by the apparently anomalous circumstance of the left auriculo-ventricular opening and its valve being found, on examination, to be perfectly healthy in cases in which murmur, apparently caused by valvular incompetence, had been heard during life. Such cases can be accounted for only by one of two explanations—either that a mitral murmur may be generated without regurgitation, or that derangement of the valvular function may be brought about by functional causes.

As far as regards the former of these two hypothesis, I have taken for granted that the existence of a systolic bellows-sound, possessing the usual characters of a mitral murmur in respect of situation, maximum intensity, and direction of transmission, necessarily involves regurgitation through the left auriculo-ventricular opening. This, which is the almost universal opinion among physicians who have paid special attention to cardiac diseases, is in opposition to the opinion of no less eminent an observer than the late Dr. Todd. Todd believed that a murmur might be engendered at the mitral valve in consequence of the deposition of lymph on its ventricular surface, the competence of the valve remaining quite unaffected, and, of course, no reflux taking place into the auricle; and even held that this condition of the valve could be distinguished from a condition producing incompetence by a special modification of the auscultatory signs. This opinion of Todd has been regarded with little attention, and has not been adopted, as far as I am aware, by any considerable authority on cardiac disease. Indeed, although it is generally admitted that roughening of the endocardium in the neighbourhood of the arterial orifices may give rise to systolic murmur, it is impossible to conceive how a

¹ [Dublin Quarterly Journal of Medical Science, 1868 vol45, p309.]

mitral murmur can be generated of sufficient intensity to be audible below the scapula, unless a current of blood flows through the imperfectly closed valve.¹

The second hypothesis will be discussed after the account of the subsequent case, which bears upon the question, and has some interest in connexion with it.

CASE I.—R. C., aged thirty-three, was admitted to the General Hospital on July 30th, 1867, suffering from dropsy. She was married, and the mother of three children.

She had been a healthy woman until four months ago, when she was suddenly frightened, she being then advanced in pregnancy; she did not miscarry, but from that time she began to suffer from palpitation, and soon after her confinement œdema of the lower limbs became evident. The heart symptoms and the dropsy had continued since, occasionally much relieved by treatment.

There was considerable anasarca and dyspnea, and she complained much of palpitation. The urine was not albuminous. A systolic bellows murmur was audible on placing the stethoscope over the heart, loudest at the left apex, and distinctly audible at the inferior angle of the left scapula. Its intensity diminished as the stethoscope was removed from the left apex. The heart was very often examined by the clinical class, and no doubt was entertained as to the case being one of well-marked regurgitation through the mitral valve. There was no diastolic murmur nor any bruit in the large vessels. The jugulars were somewhat turgescient, but did not pulsate, and the intensification of the second sound, pointed out by Skoda, was not observed. There was nothing remarkable in the progress of the case. It was necessary occasionally to puncture the legs and thighs to relieve the dropsy. There was much pulmonary congestion, a good deal of severe dyspnea and distress, and she expectorated frequently small quantities of dark blood. The symptoms were ameliorated occasionally for a time, but no permanent improvement took place.

I learned that about three weeks before her admission she had been discharged from hospital after having been an inmate for nearly four weeks. She had been admitted under the care of Dr. Ross for symptoms of a similar kind to those under which she now laboured, but much less in degree. Dr. Ross also regarded her disease as incompetence of the mitral valve.

On October 1st she was transferred to the care of Dr.

Drennan, who took charge of the ward in which she was, according to the system of rotation pursued in the Belfast Hospital, and she remained under his care until her death, on November 1st, 1867. It is to his kindness that I was enabled to obtain the examination after death.

The post mortem was made under circumstances of difficulty, and only the heart could be removed. It was examined carefully; the aorta and the pulmonary and tricuspid valves were found to be perfectly healthy; the mitral valve was well formed, and quite free from any evidence of disease, except a very slight thickening, about the size of a small shot near the free edge of its anterior flap. The circumference of the left auriculo-ventricular opening was found to be three inches and six lines; that of the right, three inches and eleven lines. The cavities seemed quite normal as regards capacity and shape, and the muscular structure of the heart was firm and well coloured. The carnæ columnæ were well developed and firm, and nothing abnormal could be discovered in the chordæ tendinæ. I exhibited the heart, and read the notes of the case, at a meeting of the Ulster Medical Society, and it was carefully examined by several members of considerable experience in pathology and anatomy who were present, and the unanimous opinion was, that there was no evidence of their being anything whatever abnormal in its condition. The heart was specially examined with reference to the suggestion which has been put forward by some observers¹—namely, that atrophy of the muscoli papillares and smallness of the chordæ tendinæ may become important causes of valvular incompetence, but with an entirely negative result.

The appearance of the valve, as well as the symptoms and physical signs, presented a remarkable resemblance to Case I., published in the first of the admirable papers on "Diseases of the Heart," by Dr. M'Dowel.² In Dr. M'Dowel's case, however, great dilatation of the left ventricle, and softening of its muscular tissue, existed, a condition which, as has been insisted on by Dr. Gairdner, may produce regurgitation through the auriculo-ventricular opening without the existence of any disease of the valve. No such change existed, however, in this case.

Observations.—It is of interest to observe that the first symptoms of ill health occurred subsequently to the patient having been frightened, the fright having taken place when she was in the pregnant state, a condition in which the nervous system is probably unusually susceptible of injurious influences of this kind. In chorea, a disease not unfrequently observed in pregnant women, mitral murmurs are occasionally observed, and these are attributed, with much proba-

¹ "If the bellows-sound be purely regurgitant, its position is strictly at the apex; it becomes in a marked way faint as you proceed to the base of the heart, and it is distinctly audible beneath the left scapula; and, in addition, the sign pointed out by Skoda, exists—namely, a marked intensification of the second sound. If the bellows-sound be not regurgitant, you hear it well up to the base of the heart; you hear it only feebly, or not at all, at the left scapula, and there is no intensification of the second sound. I may add that, in this latter case, the heart's disturbance, and the sufferings of the patient, are in a marked manner less than in the former."—Clinical Lectures by Dr. Todd, 2nd ed., p. 77.

¹ Bristowe. Brit. and For. Med.-Chir. Rev., Vol. 20, p. 229. Peacock on some of the Causes and Effects of Valvular Disease of the Heart, 1865, p. 59.

² Dublin Quarterly Journal of Medical Science, Vol. 14, p. 354.

bility,¹ to disordered innervation of the muscular apparatus connected with the valve. The idea naturally suggested itself that the valvular derangement might have been caused by the strong mental impression giving rise to spasmodic action of some of the papillary muscles. The influence of mental emotion in causing spasm of so partial an extent as that which produces strabismus is well known, and there is nothing inconsistent with our knowledge of the very limited and local phenomena which may be engendered by nervous impressions in this supposition. Of course, antecedently, it would be highly improbable that spasmodic action should continue persistently for so considerable a period, and should give rise to phenomena of a character so regular and uniform. Intermissions and irregularity would be much more likely to occur, and for this reason Dr. Bristowe, in an elaborate paper on inorganic mitral murmurs, previously referred to, dismisses somewhat summarily the notion of spasmodic action having any influence in the causation of mitral regurgitation, and attribute the incompetence to the dilatation of the ventricle, and atrophy of the chordæ tendineæ and musculi papillares. Yet it may be reasonably doubted whether we are enabled altogether to exclude such a mode of causation. Instances have been observed both of continuous and of rhythmic spasm,² of a nature quite as extraordinary as would be involved in such a supposition. The constantly recurring irritation of the blood entering the cavity of the ventricle might possibly bring about a constantly recurring spasmodic action. Indeed, an excellent observer has suggested that even the inorganic murmurs which are so frequent at the aortic orifice may be referred to perverted innervation.³

Besides, it is impossible to refer the case which follows, and several of the cases recorded by Dr. Hayden, in a paper to be afterwards referred to, to a dilated condition of the ventricle, unless, indeed, we are prepared to admit that a condition of dilatation, so considerable as to give rise to regurgitation, is capable of being rapidly produced and rapidly removed, a view which is not consonant with pathological or clinical experience. In this case there was certainly no appreciable dilatation. It is, no doubt, difficult to pronounce

definitely on the absolute capacity of a ventricle, but any considerable dilatation would be readily recognized. It is curious, that out of six cases which are adduced by Dr. Bristowe in support of the dilatation theory, two are cases in which the dilated condition of the heart was only inferred and not actually observed at the post mortem examination; and as regards the condition of the musculi papillares and the chordæ tendineæ, in three of the six the actual condition on which so much stress is laid was also not observed.

A point, however, of much greater practical importance is the occurrence in this case of marked pulmonary congestion and of anasarca. In a very able paper, read at the recent meeting of the British Medical Association in Dublin, Dr. Hayden dwells on the absence of pulmonary engorgement as an important element in the diagnosis of inorganic mitral murmurs. It is impossible to comprehend why a regurgitation from functional derangement, of the valve should not be accompanied or followed by the same disturbance of the circulation as would be brought about by a similar amount of regurgitation owing to actual changes in the structure of the valves. Indeed, it would seem more probable that the obstacle to the return of blood from the lungs would be, *cæteris paribus*, greater in some of the former cases, as the incompetence of the valves would be occasionally produced rapidly, and even suddenly, while in a large proportion of cases of organic change the incompetence would be of slow and gradual growth. Nor is there any reason why inorganic regurgitation should not be of very considerable amount. The fact, no doubt, is that the amount of pulmonary congestion, and the date of its appearance, are regulated by the amount of the incompetency, by the state of the ventricle, and by the general condition of the patient. It is very probable that several of Dr. Hayden's cases would have exhibited signs of pulmonary and systemic congestion had the regurgitation not yielded to treatment.

The anasarca and congestion of the lung, which existed in my case, cannot be attributed, I believe, solely, or even mainly, to the condition of the valve. The feeble, ill-nourished, and anemic state of the patient was, no doubt, powerfully instrumental in the production of the dropsical condition. But that there was a difficulty imposed upon the heart was shown by its firm and well-developed character of tissue. Indeed, a condition of what may be called relative hypertrophy seemed to have been induced. The heart might have been reasonably expected to share in the prevailing atrophy and wasting of the body. It was, on the contrary, an organ such as might have belonged to a strong, healthy woman. This points towards a cause having existed which kept up an abnormal stimulation of its nutrition, and renders it probable that had life been much prolonged actual hypertrophy would have been produced.

CASE II.—Mitral Regurgitation of a Temporary Kind.

¹ Walshe. *Diseases of the Heart*, 3rd ed., p. 96.

² *The Nervous System*, by Sir Charles Bell, 1830, Appendix, p. 41 and 42. Parry, quoted by Romberg *Diseases of the Nervous System*. Vol. i. p. 287.

³ "It is certain that, even when spanemia and anemia exist, functional murmur is commonly confined to cases characterized by palpitation—a result of nervous irritability—and that profuse venesection, hemorrhage, and other causes of spanemia, are also productive of palpitation, and of exalted nervous excitability. Therefore, without denying that an anemic and spanemic condition of the blood must necessarily facilitate the production of vibration and murmur, it seems to me probable that these functional murmurs are more closely connected with perverted innervation and disordered contractility of the valves and large vessels than with a mere alteration in the condition of the blood."—Fuller. *Diseases of the Heart and Great Vessels*, p. 47.

A gentleman, aged thirty-three, married for about two months, of strictly moral and temperate habits, and who had always enjoyed excellent health, was seen by me in consultation with Dr. Newett, of Moneyglass. He suffered from great exhaustion, and from a feeling of faintness when he sat up more than a few minutes at a time. He had injudiciously taken purgative medicine with the idea of his illness being the result of biliousness, and, in consequence, the bowels were rather relaxed. There was no evidence of active disease of any kind; the tongue was clean, pulse 80, and very soft, and there was some appetite. On examining the heart a soft bellows-murmur was heard at the left apex, transmitted towards the left axilla, but quite inaudible at the base of the heart, and only faintly audible at the right apex. He had never had any rheumatic affection, nor any symptom of cardiac disease, and he had been examined for life assurance a short time previously by an excellent and careful stethoscopist, who had not detected any abnormal condition of the heart. Under these circumstances, I inclined to the opinion that the murmur was of functional origin, an opinion which was verified by the progress of the case, as under tonic treatment and rest he completely regained his strength, and the murmur gradually subsided. I had an opportunity of examining his heart a few days ago, and found that its action and sounds were perfectly normal, and free from any trace of murmur.

The conclusions to which a consideration of the last two cases and observations lead are—firstly, that mitral regurgitation may be produced without organic disease of any kind, and—secondly, that it may in some instances give rise to the same physical signs and to the same general symptoms as regurgitation from organic causes.

Mr. H. M. Johnston exhibited a gangrenous leg which he had amputated. It had occurred as a sequel of fever.

508 Notice of meeting on 14th February 1868
The Thirteenth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 14th instant, at Half-past Seven o'clock.

Business.

Dr. William Mac Cormac will give a short account of a Case in which he performed an Early Operation for Cleft Palate, and for Hare Lip.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for

Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 12th February, 1868.

Thirteenth Meeting, 14th February, 1868

Present, Professor Cuming, Drs. Fagan and John Moore.

Adjourned the meeting till this day week.

508 Notice of adjourned meeting on 21st February 1868

An Adjourned Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 21st instant, at Half-past Seven o'clock.

Business.

Dr. William Mac Cormac will give a short account of a Case in which he performed an Early Operation for Cleft Palate, and for Hare Lip.

Dr. John Moore will read a Paper on The Influence of Flax-Spinning on the Health of Mill Workers.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 19th February, 1868.

Thirteenth Adjourned Meeting, 21st February

Dr. William MacCormac in the chair. Members present, Drs. Hill, H. S. Purdon, Fagan, McCrea, Johnston and John Moore.

Dr. William MacCormac introduced a patient in whom he had operated for cleft palate and for hare lip nearly two years ago, and gave a description of the case.

He also described a case of operation for hare lip which he performed in a child eight days.

He also exhibited a testicle which he had removed for medullary disease.

Dr. John Moore read a paper on “The Influence of Flax Spinning on the Health of the Mill Workers of Belfast”.

Paper:¹ One of the objects of this Association being “to collect statistical evidence of the relative healthiness of different localities, of different industrial occupa-

¹ [Published in the Transactions of the National Association for the Promotion of Social Science, 1867, p508, having been first read to that society during its meeting in Belfast in 1867.]

tions, and generally of the influence of external circumstances in the production of health or disease," I should regret exceedingly were its Meeting at Belfast to be permitted to separate without any information being laid before it on these important subjects in relation to our local manufactures, which employ so many thousands of hands, and which has raised Belfast to the proud position which it now occupies. I have thought that the experience of one who has medical charge of more than three thousand of our mill workers might not be devoid of interest to those who labour for the improvement of the working classes. So far as my experience goes, and it has been gathered from a wide field of observation, I believe that the manufacture of linen yarn and linen, in relation to the health of those engaged in it, will be found to bear a favourable contrast with that of any other in the kingdom.

The manufacture of linen may be said to begin when the farmer, after "pulling," "watering," and "grassing" the flax, delivers it at the scutch mill to be prepared for market. It is here, namely in the scutch mills, that the greatest danger to life and limb in the whole process of the manufacture is to be found. Scattered here and there in remote rural districts, removed from the eye of any Government Inspector, the revolving machinery, too often without sufficient safeguards, frequently makes sad havoc of the hands and arms of those employed in that department of the linen manufacture. It is, however, with the manufacture of linen yarn and linen, as carried on in the spinning mills and weaving factories of Belfast, that we are at present engaged; and here, as I have stated, that without exposure to the influence of any noxious gases or emanations, without any un-natural or constrained positions, and without excessive muscular exertion, the employment will be found, if not one of the most lucrative, at least one of the most healthy in the whole range of our manufactures.

The first process to which the flax is subjected is that of "roughing," and those who perform that operation are accordingly called "roughers." The process consists in drawing the fibres of the flax across a coarse iron comb. The atmosphere in which they work is certainly not one of the purest, the dust and fine particles of the flax load the air, and consequently a good deal of bronchial irritation results. The floating particles, however, are so unlike, for instance, those to which the grinders of Sheffield are exposed, that they are comparatively harmless. From the roughers the flax is passed to the machine boys, whose task it is to fasten it between two iron plates by means of screws, and pass it across a machine where it is subjected to a further process of combing or dressing.

This, with the exception of the carding, to be afterwards mentioned, is, perhaps, the most dangerous position to which any of the mill-workers are exposed; it is amongst the machine boys that the greater number of

accidents occur, and I am seldom without one or more of them under my care for wounds and laceration, and, too often, mutilation of the fingers and hands. This results, no doubt, to a great extent from the fact that boys will be boys, and that their familiarity with danger breeds contempt, and the carelessness that consequently arises leads to these deplorable results.

The machine boys, like the roughers, are exposed to an atmosphere loaded with dust and floating particles of the flax. The sorters next take up the process, and their occupation closely resembles that of the roughers; their business is to subject the fibre of the flax to a further process of combing, and more care and skill is required on their part, to arrange and sort the different qualities of flax submitted to them.

There is no machinery employed either by the roughers or sorters, the operations of both being performed by hand; they are, consequently, free from those dangers which must always result from being in close proximity with revolving machinery, no matter how securely it may be guarded.

Roughers, sorters, and machine boys are all exposed to an atmosphere which, I believe, might be rendered much purer and more wholesome than it is; a little engineering skill applied in that direction, by directing a current of air so as to carry away the impurities, would certainly be a step in the right direction.

The flax having gone through the hands of the roughers, machine boys, and sorters, is then sent to the preparing room, where it passes through a series of more complicated operations, and receives the first twist into yarn. The toil in all these operations is light, care and attention being what is required on the part of those engaged. So far as my observation extends I have not succeeded in discovering any disease which arises specially from, or can be traced to, the nature of the occupation of those employed in the "preparing room."

Before speaking of spinning properly so called, there is another operation to which that portion of the flax which has been separated by roughing, by machines, and by sorters, and which is called tow, is subjected, namely, carding; this I look upon as the dustiest, most disagreeable, as well as the most unwholesome and most dangerous of all the departments connected with the spinning of flax. Accidents, when they do occur, in connexion with the carding machine, are generally of the most frightful character, and fatal in their results.

The remarks made on the desirableness to improve the atmosphere of the machine-room and the hackling-shop apply with still greater force to the carding-room; fortunately, fewer hands are employed in it than are engaged in any of the other departments of the manufacture.

The process of spinning comes next to claim our attention. And here we find a complete transition of circumstances; passing from a cool dry atmosphere, loaded with floating particles and impurities, we enter

a heated atmosphere charged with vapour—in fact a vapour bath—with a temperature from 80 degrees to 85 of Fahrenheit's thermometer. More than 30 per cent, of the workers are employed in this department of the manufacture.

As it is in the machine-room that little boys are employed, it is in the spinning-rooms that little girls are engaged, and here it is that the tender form of childhood is often in danger of being taxed beyond what it is able to bear. The diseases found to prevail and to spring from employment in the spinning department are anæmia, onychia, and the deformity of the foot—a species of talapis.

Those who have been long in the atmosphere of the spinning-room generally become pale and anæmic, and consequently pre-disposed to those ailments which spring from such a state of the constitution.

Children placed there early and compelled to keep upon their feet the entire day, as the nature of their employment obliges them to do often, suffer from the young and tender bones, which form the arch of the foot, being crushed and flattened.

The onychia of mill-workers prevails to a great extent amongst the spinners. It is a most inveterate disease, and requires for its remedy a most painful operation, either the dissecting out or wrenching out the entire roots of the great toe-nail. It results, I believe, from the custom which is universal here with that class of going barefooted while at work; the water which has filtered through becoming more or less impregnated with the brass and other metal of the machinery, when any accidental knock lights up inflammation, it comes to act as an irritant and poison, and hence results the painful and tedious ulceration around the great toe-nail which requires so severe a remedy.

There is also a form of papular eruption to which the spinners are liable upon the face and arms, caused, I believe, also by the water through which the threads have been drawn. It is one which does not cause any derangement of the general health, and for which a remedy is seldom sought.

I have now to speak of the last process in the manufacture of linen yarn, namely, reeling. It consists in causing to revolve a number of pieces of wood arranged around a central axis, and by means of which the yarn is unwound from the bobbins on which it has been spun, and formed into hanks, which when made into bunches is ready for the market. No machinery is employed in this department, the reels being turned by those employed upon them. In this department more muscular effort is required than in any other, and from the peculiar exertion necessary to keep the reels in motion, I believe that hernia will be found to exist in this class to a considerable extent.

I have thus endeavoured to describe, with the utmost brevity and, as I fear, very imperfectly, the various operations and processes in which the mill-work-

ing population of Belfast is engaged, and to trace, as far as possible, any injurious influences which those operations may exert upon the health and well-being of those engaged in them. Bronchial irritation does result to those employed in several of the departments, but contrasting the number thus affected, with others exposed, as agricultural labourers for instance, to the vicissitudes of the weather, I am of opinion, that as few cases of chest affection will be found amongst the mill-worker as amongst the same number of any other class in the community. I believe, however, there is great room for improvement in purifying the atmosphere of the carding-rooms, machine-rooms, and hackling shops.

From the foregoing statements you are likely to conclude that the mill-working population of Belfast is a remarkably healthy class, but I regret to say that the very opposite of this is the true state of the case. A large amount of sickness prevails amongst them, but its cause must be sought for in other reasons than the nature of the occupation in which they are engaged. I believe we shall not find much difficulty in discovering the root and source of their great bane. Any one who will take the trouble to visit some of our spinning mills at the approach of meal hours, and examine the food which has been brought to sustain them during the day, to look into the tin vessels and see the fluid, which can hardly be called tea, infused frequently from the evening before, allowed to remain all night in metallic vessels, warmed up again not only for breakfast but for the mid-day meal, it becomes at last to resemble tobacco water more than anything else, and from the examination one turns away both sad and sickened. Improvement of the food of the mill workers must underlie all attempts to improve their general health.

An effort has been made in this direction by Dr. M'Cosh and others, and, thanks to the persevering and indefatigable efforts of Mr. T. P. Corry, the experiment has, to a great extent, proved successful. By means of the cooking dépôt which he has built, the working classes are enabled, in the locality in which that dépôt is situated, to obtain good, nutritious, and well-cooked food, on more reasonable terms than they could themselves prepare it. I had hoped that the system might have been extended in Belfast as it has been in Glasgow, and Messrs. Johnson & Carlisle kindly placed a dining-hall at Brookfield Mill, which they suitably fitted up, at our disposal for that purpose; the experiment, as such, was successful, and though difficulties in the details have caused, I regret to say, a suspension of its operations, sufficient was done to show that if placed within reach of the mill workers they would gladly avail themselves of its benefits.

I trust that ere long others will follow the example Mr. Corry has so nobly set, and that in those centres around which our busy hives of industry are clustered, there may be placed institutions similar to that which

he has placed in Dock Street. Another still more important point, and closely connected with the foregoing, is the education of those girls who are to become the wives and mothers of the working classes, in domestic duties. Trained from early youth through hard and constant toil, to spin, to reel, to weave, they are left entirely ignorant of domestic economy, and are expected to be able to practise that which they have never had an opportunity to learn.

I have endeavoured to ascertain as far as possible the actual amount of sickness which does exist amongst our mill population, but the shifting nature of that class, and the frequency with which they leave one establishment for another, render it difficult to arrive at an accurate result. I find that about forty per cent, of those actually engaged apply for medical relief during the year, and that not less than twenty-five per cent, of those who do seek medical aid seek it on account of gastric derangement, clearly traceable to the want of proper food and dietary arrangement; all the meals of a large proportion consisting of tea, resulting from the facility with which it can be prepared, and not from inability to procure more substantial nutriment.

J. Seaton Reid

510 Notice of meeting on 6th March 1868

The Fourteenth Meeting of the Society, for the present Session, will be held in their Rooms, at the General Hospital, on Friday Evening next, the 6th instant, at Half-past Seven o'clock.

Business.

Dr. William Mac Cormac will give an account of Two Cases of Strangulated Femoral Hernia upon which he recently operated.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 4th March, 1868.

Fourteenth Meeting, 6th March, 1868

The President in the chair. Members present, Drs. William MacCormac, Cuming, H. Brown, Fagan, Hill, Wales and John Moore.

Dr. William MacCormac gave an account of two cases of strangulated femoral hernia upon which he recently operated; one terminated fatally and in

which case the portion of strangulated bowel was exhibited.

Paper:¹ In bringing forward the history of these cases I do not expect to advance anything that is novel upon such a subject as hernia, which has so long occupied the attention of the best anatomists and surgeons. I merely wish to record the details of cases in certain respects not unimportant, and add, perhaps, a little to the common stock of knowledge. I would also wish to urge my conviction as strongly as I could that to operate early is to give the patient the best chance of recovery. Now-a-days, no surgeon would, I conceive, make repeated and forcible attempts to reduce a strangulated intestine. After a judicious and reasonably prolonged effort had been made to reduce the protruded part without operation, and had failed, there is hardly anything to justify much further delay. I have never lost a patient, nor seen any untoward symptom follow an operation from its having been performed early, while every surgeon must have reason to deplore the fatal consequences which ensue but too often from the long continuance of strangulation of the intestine.

Besides, if one form of hernia more than another requires the prompt recourse to the knife it is femoral hernia. The anatomical conditions under which it occurs sufficiently explain this fact.

CASE I.—Martha Kelly, a thin delicate woman, about forty-eight years of age, and the mother of seven children, was admitted to hospital under my care on the morning of the 26th October, 1866, shortly after midnight, with strangulated femoral hernia of the left side. The patient told that for the last twenty years she has suffered from her malady, and that it made its appearance in consequence of her lifting a heavy weight just before her confinement. Something, she said, "gave way with a crack," and just as her child was being born she felt a similar sensation; and when she got out of bed afterwards a lump suddenly appeared. The woman states also that an abscess, which required to be opened, formed in the same situation. She had worn a truss, but the swelling often came down. There was no great difficulty at any time in returning the parts to the abdomen—into which led, the patient states, a large opening—until the 24th inst, at 11 p.m., whilst at stool the hernia came down, and the woman could by no effort of her own return it. A medical man was sent for the next day. He tried the taxis, prescribed castor oil, and the application of ice, without success. The castor oil was followed by two evacuations from the bowels, but the swelling remained as before. The taxis was then a second time tried without avail, and the patient recommended to go to hospital. My colleague Dr. Murney was present when she was admitted, and he made an effort at taxis whilst the patient was in a warm bath, but without making any change in the tumour;

¹ [Dublin Quarterly Journal of Medical Science, 1868, vol45, p487. As will be seen, the published paper contains three cases.]

and as the symptoms did not appear very urgent advised an opiate and rest in bed, until I should pay my visit in the morning.

At ten o'clock, when I first saw the case, I found the patient had slept but little, her face wore a sunken, anxious look, tongue much furred, pulse 100, and weak. She had vomited three times some bilious matter. A good deal of pain was felt both in the tumour and abdomen, and the neck of the sac was very sensitive. On examining the left groin I found an oval tumour, the bulk of half a lemon, situated transversely beneath Poupart's ligament. The swelling was not tense, was nodulated, and had the feeling of containing omentum, except at one point, where there seemed to be intestine.

After a consultation, at the suggestion of Professor Gordon, an enema was given, which brought away much flatus, and the ice was reapplied. In the afternoon the patient's condition was not at all improved, and therefore I considered it expedient to operate without further delay, as strangulation had now subsisted about forty hours.

The patient having been first put under chloroform the taxis was tried, but I failed to produce the slightest effect on the bulk of the swelling.

An incision was therefore immediately made, about two and a-half inches long, in the vertical axis of the tumour, but rather to the inner side. The fascial layers were divided in the usual manner, and the sac exposed. On opening this a small quantity of serum flowed away and omentum was seen. The sac was then more freely opened, and on introducing the finger a very tight stricture was felt at the crural ring, beneath which the finger nail was insinuated with trouble.

The constriction was divided with the greatest care, and with much difficulty, cutting upwards and inwards, at the junction of Poupart's and Gimbernat's ligaments. The protrusion, however, could not be returned, and on seeking for the cause it was found that the omentum was attached by old adhesions to the posterior part of the sac. These were separated with care, and another attempt made to return the parts, which proved unsuccessful, until Poupart's ligament was partially divided, the edge of the knife being directed upwards. Three sutures were inserted in the wound, a pad and spica bandage applied, and the patient removed to a warm bed, when a large opiate was administered.

That evening the patient was restless and uncomfortable. She was ordered a grain of opium and a grain of calomel every fourth hour.

The next morning I found she had slept well, and felt easy; pulse 120. She is to have chicken soup, and the pills at longer intervals.

On the fourth day, the 29th, the pulse was 110; bowels had been freely open the night before with great comfort to the patient. She had slept well, and had eaten an egg for breakfast. On dressing the wound it

was found to have healed throughout by immediate union. The patient became rapidly convalescent. She was slightly salivated, having, however, taken in all five pills, each containing only one grain of calomel. The inferior angle of the wound subsequently reopened at one point to discharge a few drops of pus, but otherwise the wound thoroughly and immediately healed. She was discharged from hospital in fair health, better than she had enjoyed for many years, and wearing a light truss.

CASE II. differs from the last case considerably. The notes from which I have extracted the following account were very fully and accurately taken by Mr. Price, one of my clinical clerks. The patient was much older-looking than her real age—sixty years. She was the mother of seven children, and had evidently suffered many hardships. The hernia was of recent date, and was very small. She first noticed a lump in her groin about a month ago, when she had an attack of cramps and vomiting. Since this attack she has but seldom got out of bed, as she suffered much from nausea and constipation, with weakness and loss of appetite. The lump sometimes was felt, and sometimes not, in the groin—probably the patient did not know the importance of the local ailment.

On the 11th February, 1868, at eleven o'clock in the morning, she suddenly took ill with severe cramps in the belly, and vomiting, not being able to retain either food or drink. A medical man was sent for some time after, who employed the taxis without avail, and then she was sent to hospital, where she was admitted under my care at nine a.m., on the 14th. I saw her a few minutes after, and found her in an extremely weak condition, surface cold, face anxious, skin yellow, voice tremulous and feeble, pulse 120 and thready, tongue much coated. Since the first appearance of the symptoms she has vomited almost continuously, even on drinking cold water, and there has been no action of the bowels. In the right groin there is a little hard lump, not much larger than a cob-nut, just beneath Poupart's ligament. Great pain was felt in the part, and also at the umbilicus.

The case appeared to be one that would brook no delay. The tumour was very tense and small, the symptoms were very urgent, and strangulation had subsisted seventy hours. The woman was at once removed to the operating theatre and chloroform administered. No attempt at taxis was thought expedient, and herniotomy directly proceeded with. A vertical incision, commencing just over Poupart's ligament was made, some fascial layers divided on the director, and a lobule of fat about as large as a hazel-nut exposed. This resembled extremely a piece of omentum, and caused much embarrassment in the course of the operation. By careful isolation of the neck of the tumour this fat was shown to be external to the sac, being contained in the fascia propria. The falciform border being exposed it was divided, cutting directly upwards, and an effort made

to return the hernia without opening the sac. In this we entirely failed, and it became necessary to open the sac. This was accomplished with great care and some difficulty. A few drops of dark red serum flowed, and a very small bit of intestine, almost black in colour, and completely adherent to the sac by recent lymph adhesions, was laid bare. The adhesions were cautiously broken through with the finger and the handle of the scalpel. The director was then introduced beneath Poupart's ligament, as the finger or even the nail could not be inserted, and the stricture freed by simply pressing the knife against its edge in a vertical direction. The intestine now receded of its own accord, the thickened sac was cut away, the wound closed by three sutures, and dressed in the usual manner. With regard to the after-treatment, it may be simply comprised in the statement that the patient was let alone. No medicine was given of any kind. Soda water and ice were freely taken to relieve the sickness following the chloroform, and so soon as this had subsided the patient was given some nourishing soup. Next day, the 15th, the pulse had fallen to 90, and the countenance had lost its anxious expression. The abdomen was distended with flatus, but not tender, except in the region of the wound. The sickness and vomiting had quite abated. On the 16th, the patient complaining of much uneasiness in the groin, the dressings were removed, and the wound was found united by the first intention throughout. The skin around had become inflamed, and was of a dark red colour. The sutures were removed, and the cicatrix yielded in the centre to the extent of a line's breadth, giving exit to nearly a tablespoonful of sanious pus.

Next day the patient was found to have been completely relieved. She had slept well, the tongue was cleaning at the edges, and the pulse fallen to 84. The skin was cool, all sickness had disappeared. No pain was felt in the abdomen, which was still, however, much distended with flatus.

On the 20th, the seventh day after operation, the patient's general condition is reported very satisfactory. A small quantity of rather fetid pus was daily discharged from the wound, which was syringed out with carbolic acid lotion with great advantage. The bowels had not been open since the operation, and an enema of soap and water was directed to be given. A plentiful discharge of both feces and flatus followed, to the great relief and comfort of the patient. On the 22nd February the patient was pronounced convalescent. She eats, drinks, and sleeps well. The bowels had been moved naturally, and the wound was secreting a few drops only of healthy pus. Soon after she was discharged from hospital quite cured of her hernia. She was, however, advised to wear a truss.

Case III., extremely interesting in many respects, proved a fatal one, and a post mortem examination was obtained. We have in this instance an illustration of the most forcible kind of the disastrous results of

delay in procuring relief for a strangulated intestine, and an example given where the symptoms merely of disease were treated, and the cause of those symptoms completely overlooked. The account of the case is taken from the very faithful notes of Mr. Chambers, clinical clerk.

Mrs. G., thirty-two years of age, the mother of several children, was admitted under my care on the evening of Friday, February 28th. She had previously enjoyed an immunity from all serious illnesses, but had never been very strong. Between two and three years ago she first noticed a little lump in the left groin, which came and went at intervals, and was occasionally attended by cramps and pain. For three months the menses had disappeared, as she had again become pregnant, and during the 6th, 7th, and 8th of February she suffered from profuse hemorrhage and other symptoms of miscarriage. The bleeding from the vagina continued until within three days before admission, reducing her to a very weakly state.

On Friday, February 21st, whilst washing, and having to make considerable exertion, the lump in the groin suddenly increased in size and became very painful, while shooting pains were felt extending from it through the abdomen. The next day she was much worse, the pain had increased in severity, and assumed a constricting character at the umbilicus. She began to vomit, and from Saturday the 22nd, at 2 p.m., all food and drink was rejected by the stomach. The bowels were constipated, not having been relieved since Friday morning. On Sunday a medical man was called in, who prescribed her a mixture for the purpose, she stated, of checking the vomiting and opening the bowels. Different mixtures were from time to time ordered, also Seidlitz powders, sinapisms, turpentine stupes, and linseed poultices, and all without affording any relief. Matters proceeded from bad to worse until Friday morning, the 28th, when the patient herself called attention to the presence of a tumour in her groin, which on examination proved to be a hernia, and the cause of the symptoms. Shortly afterwards the woman was sent to hospital.

On admission the patient presented the appearance of a person forty-five years of age. Her face was shrunk in all its features, pale, wrinkled, and very anxious, the angles of the mouth drawn down, the surface was quite cold, the extremities clammy, and the hands blue. The respirations were 25 per minute, the pulse was 120, and almost imperceptible. In short, nearly complete collapse had taken place. The intelligence was perfect. There was little or no local or general tenderness on pressure. The woman complained only of deadly sickness. The vomiting has continued without intermission since the commencement of the symptoms, and the matter ejected is now of a most offensive description, being intolerably fetid. The tumour lies below Poupart's ligament, which it slightly

overlaps. Its long axis is transverse, and measures two inches and a-half, while from above downwards it is about one and three-quarter inches. There was no tension, and, as before stated, little or no tenderness evinced on pressure.

My opinion was that the taxis should not be attempted, and that an operation, although the result was hardly doubtful, should be attempted. After some chloroform had been administered an incision, nearly vertical, was made over the tumour, and after dividing several layers of fascia a dark fatty tumour, the size of a walnut, and quite smooth and glistening upon the surface, presented itself. It was extremely difficult to decide as to whether this was a mass of omentum or not. I considered, however, after a careful examination of its appearance and relations, that it was only thickened sac, and proceeded to divide it on the director. Two lines depth of tissue were cautiously divided, and the intestine became visible, completely adherent to the sac by recent lymph. No serum escaped. The adhesions readily gave way before the handle of the scalpel, when the incision into the sac had been enlarged, and a small knuckle of the intestine was exposed, almost black in hue, but it had not lost its resilient appearance or glossy surface.

The stricture was relieved by pressing Sir A. Cooper's knife against some fibrous bands felt with the finger, and dividing them almost directly upwards. The stricture was comparatively superficial and easily divided, and there was no bleeding. The intestine was readily returned. Sutures were now inserted, and the wound dressed.

The patient was then removed to bed, surrounded with warm water jars, and given ice to suck. Next morning the report is that there had been no vomiting since the operation, but the surface was still cold. She has had a continual desire to go to stool, and feels as if she had frequent motions in the bed, no assurance persuading her to the contrary. She has been very restless, constantly tossing about, and throwing the clothes off her. She was ordered to continue the ice, to have four ounces of port wine, a few spoonfuls of soup occasionally, and in addition a grain of opium every third hour. She afterwards got more wine and opium, and in addition hot punch, combined with the warmth externally.

The next day, in spite of all that could be done, the collapsed condition increased, the pulse became slower and slower, and weaker and weaker, till it ceased to be perceptible. The surface became stone cold. The jactitation was excessive, and painful to witness. She complained of no pain, and answered questions slowly but with intelligence. Towards the last there was some muttering delirium. She finally sank some thirty-two hours after the operation. If the fatal result was not retarded, it certainly was not hastened in any way by the surgical proceeding.

A short time afterwards a post mortem examination

was procured. The parts involved in the operation were carefully dissected and the falciform border of the fascia lata exposed. It was then seen that Hey's ligament had been divided for about two lines depth, upwards and very slightly inwards. Neither Poupart's nor Gimbernat's ligaments had been touched. The crural ring barely admitted the forefinger. On laying open the abdominal cavity the small intestine, greatly distended with gas, bulged out. The crural ring was closed by a coil of comparatively healthy gut, whilst the portion which had been strangulated was discovered removed about three inches to the right side of the opening. The whole intestine seemed injected and inflamed, but there was very little effused lymph and no serum contained in the cavity of the abdomen.

About three feet of small intestine were now carefully removed for subsequent examination. Towards the lower portion of the ileum the seat of strangulation was clearly seen. About two-thirds of the circumference of the bowel at its convexity was sacculated, a deep sulcus forming its boundary. The part appeared as if it had been tightly tied by a cord, and afterwards set free. More lymph was seen near this than elsewhere, and the included portion was quite black. There was no sign whatever of extravasation, and in fact none had occurred. The amount of congestion and inflammation of the bowel was much more intense below this point than above it. The intestine was now opened along its mesenteric attachment. At the seat of stricture, for the greater part of its extent, there was a projecting rim caused by the constriction, but through a distance of about half an inch at two places, the mucous and muscular coats had completely ulcerated through, nothing remaining but the serous, which was quite translucent. At one point for a line's breadth the serous coat also had given way, but it must have done so during the process of removal.

In the first of these examples the hernia was of ancient date, the opening through which it came was comparatively large, and the symptoms which followed strangulation were not very acute. It was proved during the operation that there was an impossibility of effecting any good by the taxis, or of reducing the hernia, except en masse, without opening the sac. The patient, too, had most confidently asserted, and, as she had suffered from rupture for twenty years, it might be presumed she ought to know, that the hernial protrusion completely disappeared when she lay in bed, and that she could pass her finger up through a large sized hole into the belly. The adhesions discovered during the operation were old and required a careful and troublesome dissection to liberate the parts. It was only too after a free division of the ligamentous structures composing the crural ring that reduction could be effected without force. It requires but little consideration to arrive at the conclusion that it is better to incise the site of stricture as often and as freely as may be neces-

sary rather than handle the intestine much, or attempt to squeeze it through an insufficiently relieved stricture. Of course, for the future strength of the abdominal wall, it is important to make the incision as limited as possible, but at worst a free incision will result in a mere infirmity, whereas much manipulation of the contents of a rupture, morbidly inflamed as they usually are, is a source of extreme risk to the patient's life.

In the second case the hernia was quite recent, and the symptoms complained of by the patient were much more urgent. I only feared that, after the length of time that had elapsed from their commencement, I might find the intestine irretrievably damaged. A few hours will, as we know, in some instances suffice to produce mortification of the gut. In neither of the first two cases could reduction be accomplished until the division of the deeper structures was effected. In neither was the falciform border the constricting cause.

The third case forms a striking contrast to the others. It may seem almost unnecessary to dwell upon the importance, the absolute necessity in fact, of determining the presence or otherwise of hernia in cases of vomiting and constipation. In this instance, however, the medical man was not aware during a period of six days that there was a rupture, and the woman was treated by means calculated to benefit her, perhaps, had the cause of her malady been other than what it was, but only tending to injure seriously her chances of recovery from strangulated femoral hernia. Besides, much valuable time, which is a matter of greatest importance, was lost. I would wish to add that it is not sufficient, especially with those in the humbler ranks of life, simply to inquire if there be a lump in the groin, and rest satisfied with the patient's assurance that there is none. Oftentimes persons of this class are liable to overlook, or attach little importance to, the presence of such tumours, and even if of long standing, will sometimes forget or ignore their very existence. We know, too, how far feelings of false delicacy will carry some women. Nothing save a careful examination made with one's own hands, and eyes if needful, will suffice.

The examination of the parts after death renders this case doubly interesting. The evidences of general peritonitis were distinct, but not to so large an extent as I have frequently seen them. The patient seemed rather to die from the collapse induced by the disease, and her state, weakened as it was by the recent abortion, did not offer the same amount of resistance and power of reaction. The woman did not, I consider, die of the operation, which did not seem to affect much the progress of her case in any way, save by giving relief from the vomiting. The way in which she died appeared to me almost identical with that in a fatal case I witnessed of strangulated femoral hernia where no operation had been performed. In both instances intense restlessness and jactitation, pervading coldness, muttering delirium, from which the patient could be

aroused, and comparative absence of local tenderness and pain were very noticeable.

I send round a preparation of the intestine at the strictured part; it shows very beautifully the primary yielding of the mucous and muscular coats of the bowel. The thinned layer of serous membrane still remaining could very easily have been ruptured had any great effort to reduce the tumour by the taxis been employed.

In Mrs. G.'s case the falciform border alone was incised in an upward direction, and very slightly inwards. Vidal insists that this forms the constant cause of strangulation. Dupuytren must have thought the same, for he cut upwards and outwards, while Guthrie and Velpeau cut directly upwards, when relieving the stricture.

I performed a somewhat similar operation, in every instance, by means of an almost vertical incision, inclining slightly towards the umbilicus. The stricture was incised in nearly the same direction as the external wound. By avoiding all cutting or sawing motions, and simply pressing the edge of the knife against the tense fibrous tissues no risk of injuring an important part can occur.

A circumstance pointed out by Key was very well marked in the two latter examples. In both a quantity of fat, simulating the omentum very closely, was contained in the layers of the fascia propria, and it was a very difficult matter to discover what it really was.

The more one sees of hernia, and especially of femoral hernia, the more, I think, one becomes impressed with the necessity for early operative interference. It is not the operation, but the want of operation that proves fatal. Ill directed, and too often repeated efforts at taxis, conjoined with unnecessary delay, are only too frequently the fatal elements present in hospital cases of hernia. I opened the hernial sac in all three examples, and the condition of the contents proved that it was best to have done so.

The advantages of opening the hernial sac are great and apparent, whilst any proportionate disadvantage accruing from such a course is, to me at least, by no means so plain.—March 6, 1868.

J. W. T. Smith

511 Notice of meeting on 20th March 1868

The Fifteenth Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 20th instant, at Half-past Seven o'clock.

Business.

Pathological Specimen

Dr. J. W. T. Smith will read notes of a Case of Cancer of Stomach and Liver, and exhibit the recent parts.

Paper to be Read.

Dr. Hill will read a Paper on a Case of Suppression of

Urine complicating Pregnancy.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 18th March, 1868.

Fifteenth Meeting, 20th March, 1868

Dr. J. W. T. Smith in the chair. Members present, Drs. Stewart, Hill, H. Brown, Professors Cuming and Dill, Drs. Murray and John Moore.

Dr. Smith read notes of a case of cancer of stomach and liver and exhibited the recent parts.

Dr. Hill read a paper on a case of suppression of urine complicating pregnancy.

Paper:¹ M. B., aged thirty-five years, mother of six healthy children, had a severe attack of some chest affection, from which she never regained her former strength.

Shortly afterwards she became pregnant, and when about four months gone she experienced pain in making water, at the same time passing very little. The symptoms gradually increased in urgency, notwithstanding various methods of treatment, till the pain prevented her from sleeping, and she did not pass more than three ounces of urine in the twenty-four hours, which, however, latterly became highly concentrated. She did not complain of cough, though otherwise she presented a phthisical aspect.

At seven months labour occurred, with complete relief to her urgent symptoms, but immediately phthisis became developed, and she sank twelve days after delivery. The case was adduced as one showing the remarkable power which pregnancy possesses of keeping the symptoms of phthisis in abeyance. No explanation of the pain could be offered, but Dr. Smith, who had seen the case in consultation, suggested that it might have been caused by the irritation of the bladder by the concentrated urine.

Professor Dill exhibited a cephalotribe and the head of a child which he had extracted therewith. He believed the case was the first in which that instrument had been employed in Belfast or in the North of Ireland, and described the ease with which he was enabled by its assistance to extract the child.

Dr. H. M. Johnston exhibited the heart and lungs of a child whose death had taken place suddenly and

where it was difficult to say what was the cause of death.

Thomas Reade

512 Notice of meeting on 3rd April 1868

The Sixteenth Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 3rd instant, at Half-past Seven o'clock.

Business.

Paper to be Read.

Professor Cuming will exhibit recent parts in Case of Aneurism of the Thoracic Aorta, and will read notes of the case.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 1st April, 1868.

Sixteenth Meeting, 3rd April, 1868

Dr. Thomas Reade in the chair. Members present, Professor Cuming, Drs. Whitaker, Wales, Fagan, D. Moore, James Moore, H. Brown, John Moore, Murney, H. M. Johnston.

Professor Cuming read notes of a most interesting case of thoracic aneurism and exhibited the recent parts.

Paper:¹ James Sterling, aged thirty-eight, labourer, married, was admitted into the Belfast General Hospital, January 25th, 1868.²

Family History.—The patient and one sister are the only surviving members of a family of seven, the others having died young. Father died of fever; mother of dysentery.

History.—He has always been temperate and healthy; has never had syphilis. He was engaged at easy work until lately, when he got employment in a ship-yard. Here he was often obliged to lift and carry heavy weights. He was engaged about seven weeks in this employment, when he began to notice a whistling in his breathing, and to observe that his breathing became difficult when he carried heavy burdens. The whistling at first was observed only during expiration, but afterwards with both inspiration and expiration. The sound became gradually louder, and was increased by exertion and by going into the cold air from a house. The

¹ [Dublin Quarterly Journal of Medical Science, 1868, v45, p304.]

² Reported by Mr. Andrew Hegarty, Clinical Clerk.

first symptoms of noise and difficulty of respiration were noticed about the end of December.

Present Symptoms.—The respiration is distinctly but not loudly stridulous, and there is no dyspnea when the patient is perfectly quiet. On the slightest exertion, however, such as sitting up or turning in bed, the stridor becomes loud, and distressing dyspnea is felt, which is still further increased by walking, and the stridor becomes audible at a considerable distance from the patient. The dyspnea is not influenced by position. He has a troublesome cough, which has nothing peculiar in its sound, and a scanty glairy expectoration. Tongue clean, appetite good, bowels regular; he sleeps pretty well; pulse 75, when quiet and in the recumbent position, but greatly accelerated by exertion. The patient is pale, and has an anxious expression, but is tolerably stout and well nourished, although he states that he has latterly lost flesh; voice slightly husky, but not impaired in strength.

Physical Examination.—A prominence is observed at the junction of the second rib with its costal cartilage, and the sternum is somewhat convex and bulging at a point corresponding to this. No thrill or pulsation is perceptible; percussion over the prominence elicits a dull sound, but only when the stroke is made on the side furthest from the sternum; every where else the sound is quite normal; on auscultation the stridor seems loudest at the sternal notch; no difference in the respiration can be noticed on examining the two sides. There is a slight prolongation of the first sound at the base of the heart, hardly amounting to murmur. With this exception there is no abnormal sound to be detected. I made a laryngoscopic examination, but the patient did not bear the mirror well, and the attempt was productive of so much dyspnea that it was not repeated; as far as it was seen the larynx seemed healthy. He seemed much benefited by the application of a couple of leeches to the trachea every alternate night, and by a little paregoric. Complete abstinence from exertion was enjoined.

February 21st.—Some streaks of blood were observed for the first time in the sputum, and a little was noticed occasionally during the subsequent fortnight, the quantity never exceeding a few drops in the day. I ventured to make the diagnosis of aneurism, and in a clinical lecture delivered at this time on this and two other cases of aortic aneurism which happened to be under my care in hospital at the same time, I drew the attention of the students to the positive and negative results which the examination of the patient gave us.

1st. Prominence and slight dulness at a particular part of the chest 2nd. Stridor and dyspnea of recent origin, and greatly aggravated by exertion.

On the other hand we had total absence of auscultatory signs, of pain, of characteristic cough, of any marked alteration of voice, of dysphagia, of inequality of the pulses or of the pupils, and of any venous congestion. With regard to the prominence and dulness, I

attached little weight to its presence, as there was no pulsation or thrill or bruit detected over it, and I based the diagnosis mainly on the symptoms of dyspnea and stridor, the larynx being free from disease, and the probabilities being greatly against tumour, owing to the age and health of the patient. I ventured also to say that the aneurism must press upon the trachea itself in consequence of the respiratory sounds being equal in both sides. I suggested that possibly the hemoptysis might depend on a very minute perforation, as had been observed in some cases, and that an early and rapidly fatal issue was to be apprehended. The further progress of the case may be briefly recorded.

March 3rd.—The attacks of dyspnea, which, being previously only aroused by exertion, had now begun to appear without any apparent cause, and were of a very severe character. They occurred usually in the evening, and distressed and alarmed him very much; but they did not occur oftener than once in the twenty-four hours, and a day sometimes passed altogether without any of them supervening. I spoke to him of the possibility of tracheotomy becoming necessary during some of these attacks; however, he naturally objected very strongly to the idea.

March 4th.—After a quiet night he seemed at visit to be tolerably easy. Before I left hospital, however, I was summoned by a nurse to see him, and found him in a deplorable condition, gasping for breath, making desperate efforts to get air into the chest, the lips livid, the skin covered with cold sweat, the pulse rapid and feeble, and the stridor accompanying the respiration of the loudest description. When he saw me he said that his heart was breaking. Several members of the staff who happened to be in hospital came to see him, and agreed that tracheotomy was urgently required to avert the imminent danger of suffocation.

While we were speaking he suddenly exclaimed "Thank God! I am better," and for a few minutes seemed relieved, but the dyspnea returned with increased severity, and it was clear that he could not survive any prolongation of his terrible sufferings. He consented to the operation, which was performed by Dr. W. MacCormac, assisted by Dr. Murney, and in the presence of Dr. Smith and of myself. The breathing became at once easier, but there was still a good deal of dyspnea, which continued during the night. He was able, however, to lie down and was much relieved. He was placed in a small ward, and the air was kept saturated with the vapour of boiling water.

From this period he had no suffering whatever from dyspnea. There was some cough and expectoration of a bronchitic character for a few days owing to irritation of the air passages. He had a little morphia at night and slept well. His appetite was fair, and he was easy and comfortable, and expressed himself hopefully as to his recovery. He was able to get up and sit at the fire without any distress from the exertion, an effort which,

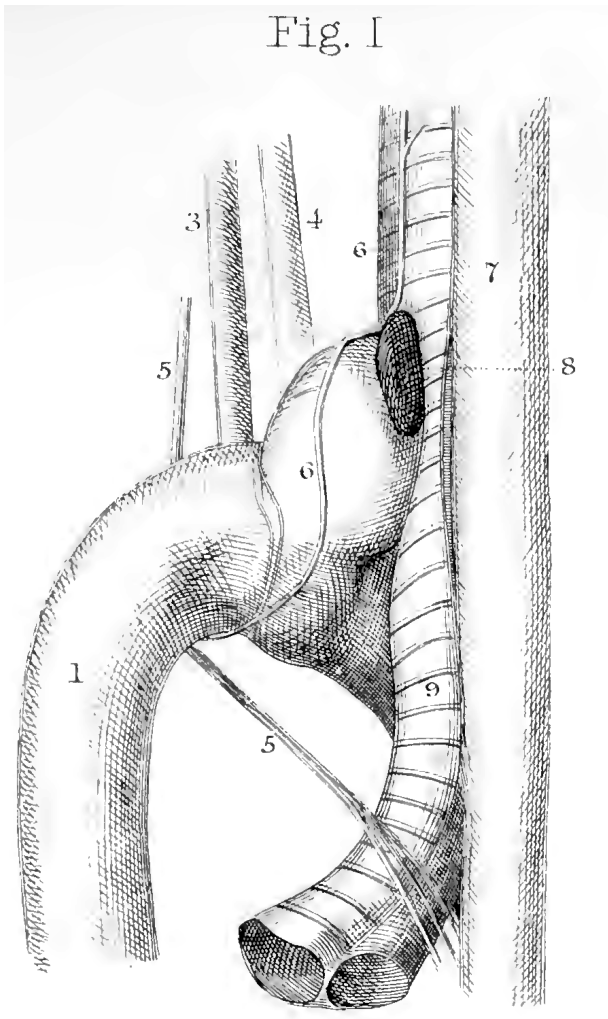

Fig. I.—The descending aorta, and a portion of the arch are turned aside to expose the aneurism.

The numbers refer to the same objects in both figures:—

1, aorta; 2, innominate; 3, subclavian; 4, carotid; 5, pneumogastric of left side; 6, recurrent nerve of same passing over the aneurism—a branch from this nerve is seen passing to the deep cardiac plexus; near it is a small filament from the sympathetic to the same plexus; 7, œsophagus; 8, an enlarged bronchial gland; 9, trachea, 10, opening into aneurismal sac.

during the previous month, would have brought on severe dyspnea. On the morning of the 23rd I entered the ward accompanied by Dr. Henry Brown and some students. He expressed himself as being very well, and was anxious to be allowed to go to a larger ward, in which he had been previous to the operation, so as to have the society of the other patients. While speaking a few drops of blood came from the opening in the trachea, which he wiped away, remarking that this was the first blood that had appeared since the operation. In a moment a gush followed; he coughed up a large quantity, which came both through the mouth and through the opening; the breathing was accompanied with a loud gurgling sound, and after a few minutes of

Fig. II

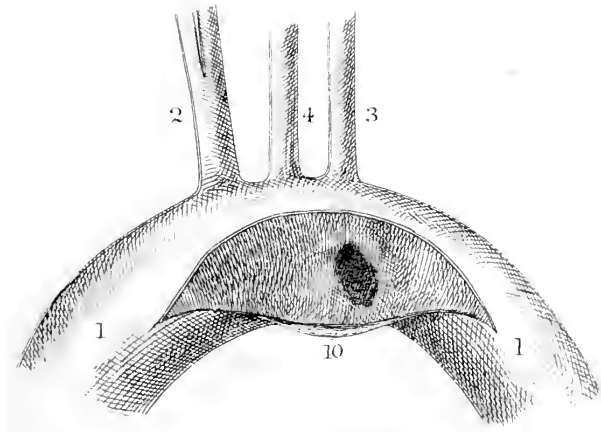

Fig. II.—The aorta laid open to show the opening into the sac.

this frightful scene, which seemed horribly long, he was dead, the heart continuing to beat for some time after respiration had apparently altogether ceased.

Post mortem.—The body was plump, and a good deal of subcutaneous fat existed. The lungs were found to contain a large quantity of blood in the air cells and bronchi, and collapsed very imperfectly. An aneurism was found pressing upon the left side of the trachea, and springing from the posterior part of the transverse portion of the arch of the aorta, below and beyond the origin of the subclavian artery. The parts were removed and were dissected with great care. The aneurismal tumour, which was about the size of a large walnut, and which is figured in the accompanying plate, had produced a considerable amount of pressure upon the side of the trachea, and had caused a projection into it which diminished its calibre considerably. There was an opening into the trachea through which a No. 4 catheter could be passed. The recurrent nerve of the left side, as well as a branch from it to the deep cardiac plexus, was found to be compressed, diverted from its course, and closely adherent to the left side of the tumour. Another small nerve, from the sympathetic, going to the same plexus, was also found adherent to the aneurism, and is figured in the plate. On the right side of the tumour a large cardiac branch of the right vagus seemed to have suffered also, but to a less degree than the recurrent. It was thickened, adherent to the tumour, and was probably pressed upon by it. The interior of the aorta showed a considerable amount of atheroma, especially in the neighbourhood of the opening into the sac. The parts beneath the prominence which had been observed during life were examined, and it was found that no cause existed within the thorax for the bulging. It had been probably brought about by the action of the scaleni, being more forcible than usual in consequence of the difficulty of breathing,

Ulster Medical Society
Session 1867–1868
President James Seaton Reid

or it was perhaps of congenital origin.

Observations.—The points of most interest in this case are:—Firstly—The possibility of arriving at a correct diagnosis of aneurism from symptoms in the absence of any physical sign derived from the organs of circulation. The case resembles closely one related by Professor Gairdner, in his work on Clinical Medicine¹—a work to which the profession is indebted for much valuable information on this interesting and difficult subject. In Dr. Gairdner's case the patient died from suffocation, notwithstanding the performance of tracheotomy, the aneurism remaining unruptured. This termination was caused by the refusal of the patient to submit to tracheotomy at an earlier period, and I have no doubt that a similar termination would have occurred in my case had the operation been much longer deferred.

Secondly—The interesting practical fact of the great relief which was afforded by the tracheotomy. Not only were the urgent symptoms which threatened speedy dissolution at once mitigated, but the patient had the inexpressible comfort of being completely free from the distressing dyspnea which every exertion had caused. He passed the remaining days of his life in what might be relatively considered ease, the suffering from the wound in the trachea being quite inconsiderable.

He was able to get up and sit at the fire for some hours daily without any suffering being caused by the necessary effort, and in all probability his life was somewhat prolonged, for the exertion which the paroxysms necessitated might have brought about an earlier rupture.

Thirdly—The almost complete integrity of the vocal functions while the respiratory functions were so seriously interfered with, and the recurrent laryngeal subjected to so much pressure. That laryngeal spasm was induced by exertion is evident, and it is difficult to get a satisfactory physiological explanation of why the voice was not to any considerable extent impaired. The slight huskiness which was noticed was not greater than occurs in cases when cough has existed for some time.

Fourthly—The interference with the nerves going to the cardiac plexus. It is possible that this may be in some cases the cause of the symptoms resembling angina, and of the disturbance of the circulation, which have sometimes been observed in connexion with aneurism. This interesting physiological point is only capable, however, of being worked out when the influence on the movements of the heart possessed by the vagus and the sympathetic system is much more clearly known than at present.

Fifthly—The explanation of the dyspnea and stridor. It was probably mainly dependent on two causes: the direct narrowing of the trachea produced by the lateral pressure on it by the aneurismal tumour, and the

spasm induced by the increased pressure on the left recurrent nerve, which was brought about by acceleration of the circulation, leading to augmented arterial tension.

The former was probably the cause of the stridor observed when the patient was quiet, which was accordingly tracheal; the latter by giving rise to laryngeal spasm was the cause of the aggravation of the symptom when exertion was made.

Mr. H. M. Johnston exhibited a bowel where the operation for strangulated hernia had been performed and where sloughing of the bowel for nearly nine inches had taken place. She survived the operation about nine months with a fistulous opening.

J. Seaton Reid

513 Notice of meeting on 17th April 1868

The Seventeenth Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 17th instant, at Half-past Seven o'clock.

Business.

Paper to be Read.

Dr. John Moore will read a paper on Mortality following Confinement.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 15th April, 1868.

Seventeenth Meeting, 17 April, 1868

The President in the chair. Members present, Drs. Wales, Porter, Hill, James Smith, Cuming.

Professor Cuming exhibited a cancerous liver.

Dr. John Moore read a paper on mortality following confinement.

519 Notice of meeting on 1st May 1868

President.

Dr. Seaton Reid.

Ex-President.

Dr. Drennan.

Vice-Presidents.

Dr. Thomas Reade.

Dr. Kelso, Lisburn.

¹ Case I. p. 455.

Dr. James W. T. Smith.

Dr. Thomson, Bangor.

Friday to Monday. Carried.

Treasurer.

Dr. Cuming.

Secretary.

Dr. John Moore.

The Annual Meeting of the Society will be held in their Rooms, at the General Hospital, on Friday Evening next, the 1st May, at Half-past Seven o'clock.

Business.

To receive Report of Council. The Report of Auditors. The election of new Office Bearers. The transaction of such other business as may come before the meeting. The installation of the President.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D., Secretary.

Belfast, 29th April, 1868.

Annual Meeting, 1st May, 1868

Present, Drs. Stewart, in the chair, William MacCormac, Dill, John Moore, Hill, Fagan, Porter, David Johnston, Whitaker, Cuming, McCrea, Rea and James Moore.

The minutes of last Annual Meeting were read and confirmed.

The Annual Report was then read. Moved by Dr. James Moore and seconded by Dr. William MacCormac "That the report now read be adopted". Carried.

The Treasures report was next laid before the Meeting with the Auditors report. Moved by Dr. James Moore and seconded by Dr. Dill "That the reports now read be adopted". Carried.

The election of office-bearers for the ensuing year was proceeded with by ballot, when the following gentleman were duly elected.

President

Dr. Cuming

Vice-President (Town)

Drs. Whitaker and McCrea

Ditto (Country)

Kelso and Dunlop

Council

Drs. Patterson, Stewart, James Moore, Sgns. M. Porter, Fagan

Treasurer

Dr. William MacCormac

Secretaries

Drs. John Moore and Hill.

Moved by Dr. James Moore and seconded by Dr. Patterson That the night of meeting be changed from

ULSTER MEDICAL SOCIETY

SESSION 1868–69

First Ordinary Meeting, June 1st, 1868

Present, Dr. Cuming, the President in the chair, Drs. Patterson, David Moore, Fagan, Angus M. Porter, Whitaker, Mr. Cantrell, Dr. Monck of Holywood and Dr. Hill.

Dr. Hill proposed and Dr. Whitaker seconded "That Mr. Ball be admitted a member of this Society."

Dr. Cuming proposed and Dr. Patterson seconded "That Dr. J. Walton Browne and Dr. Frederick E. Beck be admitted members of this Society."

Dr. Whitaker proposed and Dr. Angus M. Porter seconded "That Dr. Bolton be admitted a member of this Society."

Dr. Patterson proposed and Dr. David Moore seconded "That Dr. Barnett be admitted a member of this Society."

Dr. David Moore moved that the Librarian be requested to call in all the books belonging to the Society before the 1st July in order that the library be inspected; it was resolved that the following gentleman be the committee, Drs. David and John Moore and Hill.

Dr. David Moore introduced a patient affected with local œdema of some years standing, the progress of which he proposes observing and bringing before the Society at some future time.

Dr. Monck of Holywood exhibited some pearl-like calculi which had been passed from the bowel. He related the history of the case and stated that in his opinion they were gall-stones. Dr. Cuming undertook to examine them for next meeting.

Dr. W. MacCormac exhibited a fibrous tumour removed from the cervix uteri. Up until seven years ago the patient had enjoyed perfect health except that she was greatly pained at her menstrual periods when she had also very profuse discharge. After this date, however, she gradually failed in health until about 3 years ago, from which time until her admission to hospital she became rapidly worse. She then complained of pain in the back—loins—thighs—was emaciated—face œdematous—much troubled with vomiting—had profuse leucorrhœa and fœtid discharged from the vagina—difficulty in micturating which sometimes required the use of the catheter, especially at the menstrual term. She suffered much when she attempted to sit up and had in fact the cachectic aspect of malignant disease and her general condition was almost hopeless. On separating the labia a white glistening tumour was observed which seemed no-

where adherent to the vagina and was slightly moveable. It was removed by torsion and considerable difficulty was experienced in getting it out of the vagina. The tumour weighed 10 oz. and on section presented the appearance of white fibrous tissue. After removal the patient made a rapid and complete recovery and was as if snatched from out of the jaws of death. The vaginal discharge and vomiting ceased and she shortly recovered strength and left the hospital.

As time would not permit of the reading of Dr. Angus M. Porter's paper it was moved by Dr. Patterson, seconded by Dr. Whitaker, and unanimously agreed to that the next meeting of the Society be summoned for Monday 15th inst. instead of the first Monday in July.

Communications from Drs. Malcolmson and Crawford, Banbridge, were referred to the Council.

James Cuming M.D.

514 Notice of meeting on 15th June 1868

[Top of page missing. This would be the adjourned meeting mentioned above.]

[Members to be Balloted for.]

Thomas Ball, Esq.,
Fred. E. Beck, L.R.C.P.E.
J. Walton Browne, B.A., M.D.
Reuben Bolton, M.D.
Richard Barnett, M.D.

Pathological Specimen.

Dr. Murney will exhibit interesting specimens of Renal Disease.

Cases to be Read.

Dr. Angus M. Porter will read notes on Peculiar Cases of Syphilis.

Dr. Angus M. Porter will exhibit a number of Needles removed from different parts of the body.

Dr. John Moore will move—"That application be made to the Registrar-General for a fuller account of the causes of the mortality of Belfast and its district than that now published."

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with the Secretary not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to the Secretary.

Membership.—Persons wishing to be proposed for Membership will please forward their names to the Secretary, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.,
James Hill, M.D.
Secretaries.

Belfast, 11th June, 1868.

Ulster Medical Society Second Ordinary Meeting, June 15th

Present, Dr. Cuming (the President) in the chair, Drs. Monck, William MacCormac, Whitaker, Rea, Angus M. Porter, Thomas Reade, John Moore and Hill.

The minutes of the former meeting having been read and confirmed, Dr. John Moore introduced a patient, the subject of a well-marked epileptic aura. He is twenty-six years of age—married—and apparently of a nervous temperament. Does not appear to have had any epileptic attacks till at the age of seventeen years: since which time he has been so much and almost continuously troubled with a peculiar sensation in his right thumb that he is even desirous of having it removed. Has had only three or four epileptic fits and these at long intervals, but he keeps up continuous pressure by means of a cord on his thumb, and believes that the fits would be very frequent were the pressure removed. There is no history of hereditary disease.

Dr. Angus M. Porter read notes on peculiar cases of syphilis.

Paper:¹ Case 1.—Mr. L., a young, unmarried Scotchman, of fair complexion, and free living habits, contracted the disease in Dublin about ten days before coming for advice. Had never suffered from syphilis previously. Five days after connexion he noticed an inflamed spot on the upper part of his foreskin.

On September 22, 1867 (the date of his first visit), the appearance of the sore was so indefinite, that it was impossible to determine whether it was specific or not; a dry elliptical chafe being the form it assumed. Recommended rest, a mild purgative, and, locally, cold water dressing.

24th.—The dorsal part of the foreskin was considerably inflamed. The sore, on being exposed, presented a suppurating surface. There was no constitutional disturbance nor any enlargement of the neighbouring glands.

26th.—The ulcer was covered by dark sanguineous matter, the edges raised and hard. The prepuce was much swollen, but the system remained perfectly tranquil. The strong nitric acid was carefully applied, and then water dressing.

He did not come back till October 2, when, on examination, the surface of the sore was found clean, the margin, however, remaining high and indurated—there was complete absence of pain or irritation. The healing process did not seem to have commenced as yet. For the first time he appeared depressed, and had a bilious look. The various glands still remained unaffected.

Prescribed one 5 grs. Plummer's pill, to be taken each night for a week, and large doses of decoction of sarsaparilla daily, the topical remedy being altered to blackwash.

Next day he returned much better, the ulcer looking healthy.

He continued to improve till October 9, when he complained of soreness and stiffness in his right groin, for which a spica bandage was employed, and rest recommended. The chancre had begun to heal rapidly, but considerable hardness remained around the edges. Some red oxyde of mercury was dusted freely over it.

16th.—The chancre had disappeared, leaving a fine purplish skin behind it, surrounded by slight induration. The patient still complained of tenderness in the groin. He was continuing to take large quantities of the sarsaparilla decoction.

He now left, promising to return as soon as convenient, which he did on November 5, when he reported himself as completely cured. There was no hardness remaining to indicate the situation of the chancre, and the abortive bubo had quite disappeared. Up to the present he has enjoyed excellent health.

In this gentleman's case, which, from its persistency and difficulty of cure, was undoubtedly one of a specific nature, at least one feature of interest occurred, and that was the presence of induration unsupplemented by any form of secondaries. This hardness, as has been noticed, was not the result of a cicatrix, nor incidental, but evidently characteristic of the form of ulcer which it accompanied, inasmuch as it occurred a considerable time before the healing process commenced, and subsided on the disappearance of the sore.

Case 2.—Mr. A. G., of Belfast, occupied as a clerk, of dark complexion, bilious temperament, regular habits, young, and unmarried.

On October 2, 1867, he first sought advice for three non-indurated, flat, round, ulcers, two of which were situated on the mucous surface of the right side of his foreskin, and one on the left side. A large bubo had formed in the left groin; considerable constitutional disturbance was also present. He stated that he had not had connexion for six weeks, and that it was two since he first noticed the sores.

He had never been the subject of venereal disease prior to this attack. On drawing back the foreskin, he experienced intense pain; a good deal of smegma had consequently been allowed to collect, and keep the chancres in a foul condition. After the removal of all the secretions by warm bathing, the strong nitric acid was freely applied, followed by cold water dressing. Pressure, by means of a pad and spica bandage, was put upon the bubo, and perfect rest inculcated.

The following day (Oct. 3) the chancres were looking clean and not so sore, the bubo, however, was causing him considerable inconvenience. He was now recommended to use blackwash as the local remedy, and the following internal medicines:—

R Hyd. bichloridi, gr. ii.
 Infus gentianæ co., ℥viii. M.
 Ft. mist.

¹ [Medical Press and Circular, 1868 July–December, p25, p50.]

Sg. A teaspoonful at each meal, and 20 drops of the tincture of perchloride of iron three times daily. His diet to be plain and nourishing, and his mode of living regular. His bowels being confined, two teaspoonfuls of the liquid extract of senna was prescribed to be taken at bed time.

October 5th.—The aperient had acted freely, which gave him some relief. The chancres were looking better, and not causing much annoyance. The bubo, however, was intensely painful, and the system considerably disturbed.

His next visit was on October 11th, when the chancres did not seem to be doing so well, this it appeared was owing to his own dread of drawing back the fore-skin to dress them. Some red precipitate was now applied to each of them.

14th.—The change, which had taken place in the sores was most satisfactory, and the patient now felt less difficulty in applying the dressings himself. The bubo, which had pointed, was freely opened, and a large quantity of thin pus allowed to escape. The general disturbance of the system had greatly abated.

16th.—The chancres were almost healed, but the bubo continued to discharge watery matter, and was still very painful, especially when walking.

19th.—The chancres had quite disappeared; but the affected groin continued to resist all attempts to bring about a healthy condition. The diseased gland was reopened, and covered with a linseed poultice. A considerable quantity of thin serous matter subsequently drained away.

25th.—The oozing had nearly ceased, so pressure was substituted for the poultice, by means of a sponge pad and close fitting truss. At this time his general health was unimpaired.

November 3rd.—Mr. A. G. left to fill a situation in England, and had apparently quite recovered from the disease for which he was treated. He felt in excellent health, and had ceased to take the prescribed medicines. Scarcely any trace of the bubo remained.

26th.—A letter came from him, stating that the glands of his neck were swollen, and his throat sore. The general tone of his letter indicated despondency.

In reply, the following treatment was recommended—

℞ Pil Plummeri ʒi
Div in pil duodecem

Sg. One 3 times daily, with a wineglassful of decoction of sarsaparilla. Ten grains of chlorate of potass (in water) night and morning; and twelve grains of Dover's powder every second night, also a gargle containing astringents.

December 4th.—There was another communication from Mr. A. G., to say that he was no better. In answer, I advised him to take two teaspoonfuls of cod-liver oil three times daily, and to persevere with the remedies already prescribed.

Subsequently, finding no improvement in his state of health, he went under medical treatment in England.

January 20th, 1868.—He returned to Belfast, having become impatient and discouraged by the obstinacy of his maladies. His face was now covered with pustulæ, while over his trunk and limbs a squamous eruption had become thickly developed; some of the spots were bright red, others purple, and the remainder copper-coloured. His tonsils and the back of his throat were extensively ulcerated.

He was greatly dejected in spirits, and suffering from a severe cough which, on examination of the chest, proved bronchitic. His bowels were pretty regular, his tongue clean, skin moist, and pulse normal. Whilst in England, his medicines had been altered, with the exception of the Plummer's pills. He objected to take any more mercury although he had never been salivated, nor otherwise felt the unpleasant effects of this drug. Owing to his pertinacity on this point, I thought I would give the terchloride of gold and sodium a fair trial. Accordingly, he was recommended to take one of Grötzner's pills, with two teaspoonfuls of cod-liver oil three times daily; and, for the cough, an anodyne pectoral mixture containing the dilute mineral acids and muriate of morphia., together with expectorants. His throat was thoroughly cauterized with nitrate of silver, and a strong astringent gargle prescribed for frequent use.

Feb. 3rd.—He seemed in a somewhat better condition, as regarded his general health. The cough had become easier and less frequent. His appetite had improved, and he rested more comfortably at night.

The pustular rash on his face had increased, especially on the chin and forehead; where any spots had died away, a deep purple stain remained.

8th.—He was almost free of the bronchitis, and in better spirits, though he was somewhat alarmed at seeing a new form of rash present itself—viz., roseola of a very bright colour, principally situated on the chest and arms. The appearance of his face was very disagreeable on account of the confluent nature of the pustules, which in some places were discharging a yellowish matter. He had now taken 57 of the pills, or better than 2 grs. of the terchloride of gold and sodium (which quantity of corrosive sublimate I have seen remove equally severe cutaneous eruptions, and in a shorter time). Not having noticed any marked beneficial effects from this preparation, I deemed it judicious to adopt the following (without consulting my patient on the subject):—

℞ Liq. hydriod hyd. et arsenici, ʒss.
Syr. Simplicis, ʒiiss. M.

Sg. A teaspoonful in water with each principal meal. The cod-liver oil being continued.

His hair had commenced to fall out in large quantities, for which symptom Erasmus Wilson's prescriptions were adopted—viz.,

R. Ung. hydr. nit. ox., ℥i.
Adipis odoratæ, ℥iii.

Sg. To be rubbed well into the roots of the hair at bedtime:—

R. Ol amygdalæ dulcis, ℥i.
Liq. Ammon. fort., ℥i.
Spts. rosmarinæ, ℥ii.
Aq. Mellis, ℥ii. M.

Sg. To be sponged about the roots of the hair each morning.

16th.—A slight improvement was observable in the general condition of the patient, yet the cutaneous eruptions were very perceptible. With the hope of aiding their removal, one part of citrine ointment, in two of simple cerate, was directed to be rubbed on them each night.

March 14th.—The patient's general health had become very good. The skin affections were quickly disappearing, leaving the surface of the body covered with scales and crusts of various shades and sizes. The hair had ceased to fall out.

29th.—A vast improvement had taken place in every feature of the case. No ulceration of the throat remained, though on rising in the mornings a peculiar dryness was felt which a drink of cold water immediately relieved. The medicines were still continued.

April 16th.—No trace of cutaneous disease remained save some slight red marks on the face. The patient's appetite and general health were good, and he appeared in excellent spirits. All medicines were now omitted.

Mr. A. G. paid his last visit on April 20th, on which date every symptom of the disease had vanished.

In this case the plurality of the chancres, the absence of induration, and the late development of the roseolar rash, are points of some interest, as well as the absence of ptyalism during a lengthened course of mercurial treatment. It may be well to remember that cod-liver oil was administered throughout.

Case 3rd necessarily includes two parties—husband and wife.

On January 11, 1868, Mr. D. came to get advice for what appeared to be herpes preputialis. He said he had been treated for the same affection some three years before, and that the late Dr. Halliday cured him in a very short time. He remembered the name herpes to have been used by Dr. Halliday on that occasion.

The gentleman's regular habits, and unimpeached character, seemed to place him beyond suspicion of impurity of mind or body, still great caution was required in answering his pointed questions, as he seemed in greater dread of the disease than its condition at the time warranted, or his past experience should have admitted of. Considering that the patient should be prepared for the possibility of evil consequence, I reserved judgment, and suggested the likelihood of his having contracted the disease in a foul

privy, which hint he willingly accepted, as furnishing a respectable fons et origo mali.

He had been away on business in the south of Ireland, and two days before coming to me he first noticed itching of the prepuce. He was a most temperate and regular man, as already mentioned, and lived happily with his wife (who at this time was about seven months pregnant).

Rest, repeated bathings, the application of dilute lead lotion, and a mild purgative, were the remedies advised.

On January 14th he was quite free from the local disease, no irritation whatever remaining, but nocturnal perspirations had become a great source of discomfort to him; for this he was recommended to sponge with tepid water impregnated with sulphuric acid.

He returned on February 4, suffering from marked febrile symptoms (hot dry skin, headache, constipation, and quick pulse). For two days he had observed a bright scarlet rash (roseola) to come and go on his chest and abdomen. On examination the glandulæ concatinatæ were found enlarged, copper-coloured stains were discovered at the flexure of his right elbow and the back of his neck, his forehead had become very rough, but not discoloured. His throat was simply erythematous. The glands of each groin remained unaffected.

Corrosive sublimate in compound infusion of gentian, to be taken with cod-liver oil, as in case 2, also 15 grs. of Dover's powder each night, rest, and plain nourishing diet constituted the treatment at this stage of his illness. He was recommended strong alum water gargle for his throat.

Eleven days later (February 15), on visiting Mr. D. at his own house, I was glad to see that a great improvement had taken place in his health. The cutaneous disorders were dying away; his throat was much better with the exception of a small ulcer which had attacked the left tonsil.

The glands at the back of his neck were not so perceptible, and the stains mentioned before were not so distinct. He stated that he had derived considerable benefit from sponging with the acidulated water. He complained now of his eyes being rather sore, and his sight weak, but I could not detect any morbid appearances.

His wife had now unfortunately become a sharer in his sorrow, and evidently a partaker of the forbidden fruit. Her chest was as red as the shell of a boiled lobster; the glandulæ concatinatæ greatly enlarged, and the throat very sore, but not ulcerated. She was depressed in spirits, and feverish. She readily submitted to an examination, when for the first time she became aware of a number of ragged ulcers on the mucous surfaces of the labia. To the inside of each thigh was a patch of vesicles, which were highly inflamed and intensely itchy. A thick row of pustules extended up from the fundament to the end of the coccyx.

Ulster Medical Society
Session 1868–1869
President James Cuming

There was no tenderness in either groin, nor could any hardness be felt, the chancres, also, were free from induration.

After cauterizing all the chancres with nitric acid, and the pustules and vesicles with nitrate of silver, the parts were all stuped with poppy-head water, then dilute lead lotion on lint covered with gutta-percha tissue was applied, and the patient kept in bed. The internal medicines consisted of iodide of potassium in six grain doses, with three drachms of fluid extract of sarsaparilla in water, three times daily; ten grains of Dover's powder occasionally at bed time, and full doses of liquid extract of senna, as an aperient, when required. For the throat a powerful astringent gargle was ordered, containing tannic and the mineral acids.

February 18th.—Some superficial ulcers which had formed on the tonsils were burnt with lunar caustic. Calomel was dusted on the vulva and perinæum.

On the 23rd inst., considerable improvement had taken place, both locally and general. The calomel seemed to have thoroughly withered up the pustules, and the condition of the chancres had so far improved, as that no annoyance was experienced. The throat was again touched with nitrate of silver, and the other remedies continued.

On March 14th, Mr. D., who had been away on business, and persevering with the prescribed treatment, returned, complaining of severe rheumatism in his right arm, which he could not bend nor raise to his head. Febrile disturbance, ulceration of the tonsils, weakness of sight, and falling out of his hair, were the accompanying symptoms. He was now recommended Donovan's solution, and stimulating applications to the hair, as in Case 2. The following liniment greatly relieved the pain in his arm:—

℞ Lin. aconiti.
— Bellad.
— Chloroform.
— Opii aa. ℥ss.
— Camph., co. ℥ii. M.
Ft. linim.

The ulcers on his tonsils were being daily brushed with a strong solution of nitrate of silver, and thereby improved rapidly. Two days later (March 17) Mrs. D.'s right arm became affected in precisely the same way as her husband's, when the same embrocation as was used in his case proved equally efficacious in the removal of pain.

In the course of a week both parties were perfectly free from this latter symptom.

Both patients continued to improve from this forward, save as regarded the ulcers of the throat, which in each case seemed difficult of cure.

On April 14, a bald ulcer appeared on the right side of Mrs. D.'s tongue, for which she was recommended chlorate of potass in ten gr. doses, as was also her husband.

23rd.—The lady was confined of a very fine healthy son, free from any mark of disease or delicacy. For it she had a plentiful supply of milk, of which it partook freely.

Her mouth and throat had quite returned to a normal state. All remedies were now dispensed with, it being considered unnecessary to further continue their use.

Mr. D., who had been travelling on business from the preceding Saturday, arrived home on April 25th, and, I may say, almost recovered. His hair had ceased to fall out. No cutaneous eruption whatever remained, but the throat was still slightly troublesome, and his sight still impaired. I ordered him a strengthening eye-wash, and told him to continue the chlorate of potass and the oil, which he did till the end of the month, when, being apparently cured, he left off taking anything in the shape of medicine.

In this last case, or joint case as it may be termed, the first peculiarity noticed was the herpetic character of the primary disease, and the rapidity with which it was cured, contrary to the law of specific sores; secondly, the occurrence of night perspirations (generally looked on as a late symptom of constitutional syphilis) five days after the first appearance of local disease, or as soon as the latter was removed; thirdly, the development seventeen days later of secondaries (roseola, copper-coloured stains, and erythema of throat), the lymphatic ganglia of the groin remaining unaffected. Fourthly, the presence of vesicles in the lady's case on the inner surface of each thigh, precisely similar to those which were observed on the prepuce of her husband, and the absence, as with him, of glandular enlargement in either groin. Fifthly, the almost simultaneous attack of rheumatism in the two persons; and, lastly, the equally satisfactory results which attended the treatment of the one by iodine and the other by mercury; and the untainted condition of their infant when born.

Dr. Angus M. Porter exhibited a number of needles and portions of pins which he had removed from different parts of the body of a young hysterical female.

Dr. John Moore moved, and Dr. Hill seconded "That application be made to the Register-General for a fuller account of the causes of the mortality of Belfast and its district than that now published."

After a considerable amount of discussion the matter was referred to the Council.

(signed) James Cuming, President

520 Notice of meeting on 6th July 1868

President.

Dr. Cuming.

Ex-President.

Dr. J. Seaton Reid.

Vice-Presidents.

Dr. Whitaker. Dr. Dunlop, Holywood.
Dr. M'Crea. Dr. Kelso, Lisburn.

Members of Council.

Dr. Stewart. Dr. Angus M. Porter
Dr. Patterson. Dr. H. P. Rea.
Dr. James Moore, Dr. Fagan.

Treasurer.

Dr. W. Mac Cormac.

Secretary.

Dr. John Moore. Dr. Hill.

The Third Meeting of the Society will be held in their Rooms, at the General Hospital, on Monday Evening next, 6th July, at Half-past Seven o'clock.

Business.

Dr. M'Crea will introduce some patients with Arterial Disease.

Pathological Specimens

Dr. Murney will exhibit interesting specimens of Renal Disease.

Dr. Cuming will exhibit a specimen of Aneurism of one of the Cerebral Arteries.

Case to be Read.

Dr. John Moore will read notes of a case of accidental death.

Business.—Members possessing Cases or Observations of special Clinical or Pathological interest, are requested to communicate with either of the Secretaries not later than Wednesday morning in each week.

Morbid Specimens, for Chemical or Microscopic examination, should be forwarded to either of the Secretaries.

Membership.—Persons wishing to be proposed for Membership will please forward their names to either of the Secretaries, with their qualifications and Subscription.

Signed by order,

John Moore, M.D.,
James Hill, M.D.,
Secretaries.

Belfast, 2nd July, 1868.

Ulster Medical Society Third Meeting, July 6th

Present, the President (Dr. Cuming) in the chair, Drs. Dill, Fagan, McCrea, William MacCormac, J. Walton Browne and Hill.

The minutes of the former meeting having been read and confirmed, Dr. McCrea introduced a patient suffering from thoracic aneurism, who was examined by several gentleman present. After the patient had retired Dr. McCrea stated that she had come to him complaining of a burning pain in the dorsal region between the scapula which afterwards became more deep seated or more in the centre of the chest: and on examination he found a well marked aortic murmur following the first sound of the heart, and a distinct bruit in the left subclavian artery, but the prin-

cipal point of interest—and the one he was desirous of bringing before the members—was that the disease had gone so far without any well marked symptoms of aneurism—or much inconvenience. No difference was observed in the pupils nor in the radial pulses. No dyspnoea, no dysphagia, no angina. Digitalis and iron had given her great relief. Acetate of lead had had a fair trial but it proved of no service.

Dr. Dill said that though it wanted, as Dr. McCrea had stated, the principal symptoms yet it had the symptoms viz pulsation and prominence of the chest.

The President said there was no doubt it was strange what large arterial tumours could exist without dysphagia or dyspnoea. He had been a good deal struck by a method of treatment introduced by Dr. Tufnell of Dublin and more lately upheld by Dr. Waters of Liverpool viz complete rest, and he did think that absolute rest was worthy of a trial in this case.

Dr. William MacCormac then presented to the President for the Society a copy of J. Sampson Gamgee's "History of a case of successful amputation at the hip joint." On the motion of Dr. Dill seconded by Dr. McCrea it was unanimously resolved "that the best thanks of the Society be given to Dr. MacCormac for the book."

Dr. Cuming then shewed a preparation with an aneurism situated at the junction of the left anterior cerebral and the anterior communicating artery of the Circle of Willis and remarked how difficult it would be to make a diagnosis in such a case. The preparation was obtained in the dissecting room at Queen's College.

James Cuming

Ulster Medical Society Fourth Meeting, 3rd August

Present, Dr. Cuming the President in the chair, Drs. Reade, William MacCormac, McCrea, David Moore, Rea, Porter, and Hill.

The minutes of the former meeting having been read and confirmed, the Secretary read a report from the Council concerning a motion brought forward some time ago by Dr. John Moore and which had been referred by an ordinary meeting to the Council to consider and report upon.

"At our second meeting this session it was moved 'That application be made to the Registrar General for a fuller account of the causes of mortality of Belfast and its district than that now published.' And the motion having been referred to the Council they have now to report that 'After having obtained information from Dublin as to the manner in which the statistics of mortality are compiled there, they do not think it expedient that the application be made at present.'"

It was moved by Dr. Angus M. Porter and seconded by Dr. McCrea and agreed to "That the Report presented by the Council be adopted."

Thereafter at the request of the President who had to leave, Dr. Thomas Reade took the chair when Dr. William MacCormac read a paper upon lateral lithotomy with reference to a case operated upon by him, and which will be fully reported in the Transactions.¹

Dr. McCrea asked had pyæmia not likely been the cause of the fatal result.

Dr. MacCormac said he thought the fatal result was due simply to exhaustion, and not to any inter-current disease.

To this result the large abscess in the perineum which had formed previous to operation had to a great extent contributed. Whether the local or general condition of the patient were taken into account, no more unfavourable case could have happened, and the condition of the boy was such as not to admit of any delay.

James Cuming

Special Meeting, 1st September

Present, the President in the chair, Drs. McCrea, Whitaker, James Moore, H. Brown, and John Moore.

The President stated that the meeting was called for the purpose of giving the members an opportunity of expressing their views on the propriety of entertaining the Medical Officers of the Channel Fleet now about to visit Belfast.

It was moved by Dr. McCrea, and seconded by Dr. James Moore "That the calling of this meeting by the President be approved of."

It was moved by Dr. John Moore and seconded by Dr. Whitaker, "That it is not admissible at present to undertake an entertainment."

James Cuming

Special Meeting, 3rd September 1868

Present, Dr. Cuming (the President in the chair), Drs. Patterson, Fagan, Drennan, Dill, John Moore and Hill.

The President explained that at the ordinary meeting of Council yesterday it was deemed expedient that an entertainment should be given to the Medical Officers of the Channel Fleet and that if a sufficient number of promises could be obtained a special meeting should be called.

This meeting then showed that it was the desire of a number of members that a Dinner should be given and it remained now to determine the time, and other particulars.

It was moved by Dr. Patterson and seconded by Dr. Dill that Monday next at 6.30 o'clock be the day and time of entertainment. Agreed to.

It was moved by Dr. Drennan and seconded by Dr. Dill that Drs. Patterson, H. S. Ferguson and Dill together with the President and Secretaries form a Committee to make all the necessary arrangements.

It was suggested that the Annual Dinner of the Society be held now so as to enable the members to entertain the Medical Officers of the Fleet.

James Cuming

518 Letter to the members.

September 5th, 1868.

Sir

The Annual Dinner of The Ulster Medical Society has been fixed for Monday, September 7th, at Half-past Six o'clock, in the Clarence Rooms, May Street, so as to enable the Society to entertain the Medical Officers of the Channel Fleet.

If you have not already expressed your intention to be present, you are requested to communicate as soon as possible with

Your obedient servants

John Moore, M.D.

James Hill, M.D.

Secretaries

Ulster Medical Society, September 21st

Present, Dr. Cuming in the chair, Drs. David Johnston, Fagan, John Moore, H. Brown and Hill.

The minutes of the former regular meeting with those of the Special Meetings having been read and confirmed, Dr. Cuming introduced a patient suffering from progressive locomotor ataxy and gave the history of the case.

Dr. David Johnston then read a paper on a case of acute hydrocephalus in which he had succeeded in getting a post-mortem examination. It will be fully reported in the Transactions.

Paper:¹ *J. M., aged five years, an apparently strong, healthy, well-nourished boy, was seized with an attack of vomiting and purging on the night of the 16th of December last. There was nothing remarkable in his previous history, except that for a month or so before his illness he never liked to remain alone, and his mother remarked in him a great dislike to allow his head to be combed. The vomiting and purging continued up to the evening of the 17th—the day on which I first saw him. He had a hot skin, quick pulse, with great depression and nausea. The vomiting and purging subsided during the evening after the application of a mustard poultice over the abdomen and a few sedative powders.*

18th.—He appeared dull, but the pulse was lower and the skin cooler; he slept well during the night; he had commenced to take a little arrow-root and milk; his tongue was slightly furred, and he complained of headache.

19th.—Headache increased; abdomen retracted; with slight dulness of hearing and intolerance of light and sound.

¹ [Not found.]

¹ [Dublin Quarterly Journal of Medical Science, 1869, v47, p467.]

I now requested a consultation, which the parents of the boy readily agreed to, calling in Professor Cuming, who examined the patient very closely, and gave it as his opinion that he was labouring under an attack of hydrocephalus. Four leeches were ordered to be applied, one to each temple and one behind each ear; the bowels to be kept open with small doses of calomel and scammony: the hair to be taken off and cold applications to the head. The leeches appeared to produce no effect; the deafness, headache, and intolerance of light increased.

The sickness of stomach had now entirely disappeared. For the ensuing two weeks nothing of importance occurred. He sometimes sat in his cot and amused himself with toys and with his little brother and sister. He took almost as much food as when in health. One night during this time the hall door was closed forcibly, producing a great noise; he gave a sudden start and piercing cry, and appeared frightened; complained of pain in the head, and ever afterwards remained completely deaf.

Jan. 3rd.—When I called to see him he was seated on the servant's knee labouring under an attack of convulsions of the right side, which passed off in the course of half an hour, but the power of the side never completely returned, and during the course of the following month the leg and arm of the same side passed into a state of complete paralysis; but he always complained of increased sensibility of that side. His appetite remained good; his bowels were alternately relaxed and constipated. He was losing flesh rapidly.

About the 1st of March his bowels got very much relaxed; the stools and urine were passed involuntarily. A bed-sore formed over each trochanter and one over the sacrum. Emaciation was now extreme. He lay in a state of semi-consciousness. The pupils were widely dilated, but sensible to the stimulus of light. He was unable to speak; the tongue was clean and was protruded, without any divergence. His power of taste was remarkably acute, so much so that he was able to detect five drops of the syrup ferri iod. in a glass of milk.

During April and May nothing of importance occurred with him, with the exception of the formation of a few boils on the head, which suppurated freely, and discharged a large quantity of healthy pus.

In June there appeared to be a slight reaction in his system, the bedsores healed, and he improved a good deal in his general appearance.

The appetite was good; he could take during the day a raw egg, above a pint of new milk, and a cup of panada. About the first week of July his bowels got suddenly constipated, the appetite bad; he refused to take any food, except a teaspoonful of milk. The head symptoms increased. He now lay quite motionless up to the time of his death, which took place on the morning of the 12th of July, after an illness of nearly seven months. During his long illness he had grown in height remarkably; his mental state seemed to have been a complete

blank; he never spoke, but made some slight inarticulate noise when anything was presented to him which he disliked.

The post mortem was made on the following day by myself, in the presence of Dr. Cuming.

Body extremely emaciated; a large boil on the scalp, underneath which the pericranium was somewhat thickened and reddened. Head apparently disproportionately large. On opening the skull there was an almost entire absence of vascularity. The calvarium was thinner than usual, but ossification was complete. The dura mater was very tense, and on slitting it open the brain protruded. The convolutions were flattened; the brain-substance remarkably anemic and very soft. No fluid whatever was found externally. On removing the brain when the infundibulum was cut across, a jet of fluid gushed through the canal, which was quite pervious. The general ventricular cavity was found to be enormously distended by a limpid fluid amounting in quantity to twelve ounces. The ependyma of the ventricles formed a distinct firm membrane somewhat opaque and flocculent.

The brain-substance beneath it was almost diffluent and remarkably anemic. The choroid plexuses were less vascular than usual, and the membrane thickened and opaque. Some granulations were noticed on the arachnoid, especially along the course of the branches of the middle meningeal artery. These on examination presented the character of tubercular granulations.

The most interesting points in this case are:—

- 1st. The beginning of the attack with vomiting and purging.
- 2nd. The long duration of the illness, although an apparently acute attack.
- 3rd. The partial paralysis, one side only being affected, although the pressure must have been general.
- 4th. The preservation of some of the special senses with the entire destruction of others.

Finally. The possibility of the continuation of life with a brain almost diffluent and subject to so much pressure.

(signed) James Cuming

On Excision of the Ankle-Joint, being an Account of the Second Case in which that Operation was Performed in Britain. By Henry Murney, M.D., M.R.C.S., Eng., &c., &c.; Surgeon Belfast General Hospital.

COMPILER'S NOTE

No meeting is recorded for 5th October 1868 but Dr. Murney states that he presented the patient on that date. He also states that he presented the case to the Belfast Clinical and Pathological Society in 1857. That meeting also is not recorded but notice of it will be found on page 685.

Paper:¹ W. C., aged fifteen, was admitted to the Belfast General Hospital 10th May, 1856, labouring under disease of the left ankle; states that on the 26th December, 1854, he experienced most acute pain in the joint, accompanied by swelling. The pain was much aggravated by pressure or motion of the joint; believes he must have hurt or strained it, but cannot recall the exact occasion; from this time he never completely recovered the use of the articulation. He was treated at first at home, but matters becoming worse he was admitted into hospital, where he had rest, and afterwards counter-irritation. He was discharged on the 24th June a good deal improved. A fresh accession of suffering caused him to seek readmission on the 14th February, 1857. He is a delicate, strumous-looking subject, smart and intelligent. As yet the appetite is good; he sleeps well, and he has not lost flesh. There is considerable swelling around the ankle, especially at the sides of the articulation, but there is no swelling or tenderness to indicate that the astragalo-calcaneal joint is involved. The slightest motion causes pain for a considerable time. The joint was put up in splints to give complete rest, afterwards starch bandage was applied for the same object; mild counter-irritation, and then more severe irritants were resorted to, with temporary benefit. But after two months' trial his general health was beginning to suffer, and his appetite to fail. It was quite apparent operative interference was now necessary, and a consultation was held. All agreed on the propriety of removing the diseased parts, but some difference of opinion existed as to whether the case was an appropriate one for excision, or whether a better prospect would be afforded by amputation at the lower part of the leg. The principal difference being how far the tibia was involved, it was finally arranged that the articulation should be opened, and if, as was hoped, the disease was of limited extent, excision would be performed; but if it occupied much of the leg bone amputation must be resorted to. On the 21st April, 1857, the operation was performed as follows:—

An incision was commenced at the posterior margin of the tibia, about an inch and a half from its lower extremity, and carried downwards below the malleolus, then curved forwards and outwards across the instep to the outer malleolus, behind which it was carried straight up along the fibula as high as the incision at the inside of the limb. The vertical portions of this incision were cut down to the tibia and fibula at once; that across the instep was carried through the extensor tendons and the dorsalis pedis vessels. A ligature was applied to the bleeding artery, and the lateral ligaments were cut. Now that the joint was open it was determined to excise. The saw was applied to the neck of the astragalus, and the bone cut obliquely downwards and backwards, emerging at the posterior part, and slicing

off the trochlear surface with the upper portion of the facets for articulation with the malleoli. The remainder of these were taken off with the bone forceps, and lastly, the lower articular surface of the tibia with a very thin layer of bone, and the two malleoli was removed with the saw.

The synovial membrane had undergone the brown fibro-gelatinous degeneration, and the cartilage was completely removed from several points of tibia, fibula, and astragalus, while that which remained was much thinned and readily separated from the subjacent bone.

The parts were brought together by sutures, water dressings applied, and the limb placed on a splint which had a foot-piece attached at a slightly obtuse angle, it extended from the popliteal region beneath the heel forwards to the toes. His after progress was most satisfactory, in six weeks the wound entirely closed, two sinuses only remaining open. The splint was removed and starch bandage applied. He was discharged from hospital on the 29th June, 1857, nine weeks after operation.

In the Winter Session of 1857-58 his case was detailed at, and the lad exhibited to, the Belfast Clinical and Pathological Society.¹ The sinuses had closed for some months; he could lean his weight on the limb in walking, but used a stick; he had a pony, and could ride a considerable distance without pain.

He was lost sight of from that time till the autumn of 1868, when on account of the very useful limb he had it was considered of interest to exhibit him at the meet-

¹ [Dublin Quarterly Journal of Medical Science, 1870, v49, p97.]

¹ [Not found but see Item 387 on page 685.]

ing of the Ulster Medical Society on October 5th, when the following description of his condition was given:—

He is now twenty-seven years of age, muscular and strong; has enjoyed uninterrupted good health since he left hospital; is active and fond of walking, and considers the left is stronger than the right limb; does not use a stick; in progression there is a slight halt, but not more than is frequently observed from a corn.

This, to the ordinary observer, would be attributed to a slight in-turning of the toes of left foot, as when he walks the right foot is turned out, the left is placed straight. On examination there is considerable deposit of new tissue between the bones which were cut. The foot is slightly extended. This makes the toes and anterior part almost of proper length, but the heel is one inch and a half higher than its fellow, which he remedies by placing a wedge-shaped piece of cork wood in the heel of his boot.

The power of extension of the toes is as complete as in the opposite limb, and sensation is also perfect.

The first excision for disease of the ankle in Great Britain or Ireland was performed by Mr. Henry Hancock, in the Charing Cross Hospital, in January, 1851, and proved most satisfactory in every way. This case was the second, and, as described, the result has exceeded the most sanguine expectations, the patient not even requiring the support of the usual side irons for weak ankles. Since 1851 Mr. Hancock has never ceased to advocate this operation, and has frequently performed it. It has also been resorted to by other surgeons.

In a course of lectures delivered at the College of Surgeons, England, in 1867, on the Anatomy and Surgery of the Human Foot, Mr. Hancock¹ says:—

“I find that the ankle-joint has been excised thirty-two times for disease by British surgeons.

That the ages of the patients operated upon varied from four to forty-two years.

That the sexes given show the proportion of sixteen males to six females.

That of the thirty-two patients operated upon twenty-one recovered with good useful limbs, seven died, two suffered secondary amputation and recovered, whilst the result of two was doubtful.

The proportion of deaths consequently is a fraction above twenty-one per cent., a large proportion, I must admit, when compared with that of Syme's amputation. But it is not in reality so great when we inquire more closely into the matter; for instance, of the seven deaths four are reported to have died of consumption, of which disease one is stated to have been suffering at the time of operation; another died of the effects of syphilitic poison in the system. We can scarcely, therefore, attribute the deaths of these four consumptive patients exclusively to this operation; consequently, if we make allowance for them, we find the death-rate of average

cases ten instead of twenty-one per cent., while the mortality of amputation of the leg for disease in civil surgery is twenty-six per cent.”

Since that time the only case recorded is one of a partial excision performed by Mr. J. D. Hill, at the Royal Free Hospital.¹ It has proved successful, but not being a complete excision of the joint, it cannot be added to Mr. Hancock's table, so that the number now stands thirty-three operations, “with good useful limbs” in twenty-two of them.

I was fully satisfied with the progress of the case after operation, and with the usefulness of the limb when the patient was shown to the Clinical and Pathological Society nine months after excision; but I was astonished to find such strength, capability for divers movements, and absence of deformity when I saw him in 1868. As I had been urged to amputate, and not excise, I cut the extensor tendons, as already stated, but it is worthy of being noted how completely the power of extension of the toes was restored. I should also call attention to another matter. It is held, and properly so, that the dorsalis pedis and the plantar vessels should be studiously avoided. The first named was cut, yet no appreciable lowering of temperature or other unfavourable symptoms followed.

I have frequently sought for cases which would hold out a good prospect for excision, but as yet only succeeded in this one instance. Profiting by the experience of the thirty-three resections which have been performed, if about to operate now I would avoid the tendons and dorsalis pedis artery, not as absolutely essential for the well-being of the patient, but considering it desirable to cause as little injury as possible compatible with complete removal of the entire diseased articulation.

October 12th

Present, Dr. Cuming the President in the chair, Drs. Wales, John Moore, McCrea, William MacCormac, and Hill, with visitors Surgeon Barclay and Assistant Surgeon Lamb H. M. 54th Regiment. Dr. Whitaker also present.

The minutes of former meeting having been read and confirmed Dr. McCrea introduced a patient who a few days before felt a throbbing commence in her chest and immediately on putting her hand to her neck she detected a tumour pulsating violently.

On examination at different times it is found to vary, sometimes having a loud bruit with the first sound of the heart, at others no bruit. The most remarkable feature seemed to be its sudden origin for it appeared to be merely an enlargement of the thyroid gland.

Dr. John Moore then showed a tumour which he had removed from the uterus and read notes of the

¹ Lancet, 1867, Vol. ii., p. 62.

Ulster Medical Society
Session 1868–1869
President James Cuming

case. On section it presented the well-marked characteristics of a fibrous tumour. He had removed it by his fingers.

Dr. John McCrea then read a paper on “Recent Doctrines in Vital Dynamics” and showed that it was now the generally received opinion that much of the force was developed in the blood.

James Cuming

November 2nd

Present, Dr. Cuming (President) in the chair, Drs. Thomas Reade, William McGee, MacCormac, Dunlop, Wales, H. P. Rea, Andrews, Stewart, H. Brown, McCrea, S. Browne, Ross, J. W. Browne, McWilliam, Angus M. Porter, Drennan, Dill, Murray, David Moore, David Johnston and Hill. Visitors Dr. Lamb 54th Regiment and Dr. Dixon and several students.

The Treasurer made a report of the state of the funds of the Society which was adopted.

The President then delivered his Inaugural Address.

Paper:¹ GENTLEMEN—It is a portion of the duty which devolves on me, as President of this Society, to address to you some observations introductory to our Winter Session.

In the first place, permit me to return you thanks for the honour which you have conferred upon me in electing me to this chair. Nothing could be more gratifying to me than such a spontaneous mark of regard coming from my professional brethren, and I had no hesitation in accepting it, knowing that I could rely on your kindness and consideration to aid me in the discharge of duties for which I might otherwise have felt myself inadequate.

Sixty-two years have elapsed since this Society was founded; for we are the legitimate successors of those who originated the Belfast Medical Society in 1806, although its continuity was temporarily interrupted before its re-organization in 1822. In 1862, the Clinical and Pathological was amalgamated with the Medical Society, and the name of Ulster Medical Society adopted. From that period the meetings have been more frequent, and the number of contributions from the members have considerably increased.

We owe much to our predecessors in this Society. They formed and transmitted to us an admirable collection of works, amounting to above five thousand volumes, and including a large number of rare and curious works, which are invaluable to the student of the history of medicine. They have handed down to us also gifts still more precious in the memory of lives honourable to their profession and useful to the community in which they lived. The annals of a town which has produced many distinguished citizens, record no names which deserve a more honourable place than those of

Drennan and M'Donnell, who were among the original members of this Society.

In 1806, the medical profession in Belfast numbered nineteen members; the town contained 22,000 inhabitants. Now there are eighty-one practitioners of medicine, and the population of the town probably exceeds 150,000.

The period of the foundation of the Society was one of great intellectual activity in medical science. Jenner's great discovery of vaccination had been first announced eight years before, and was rapidly making its way into public notice. Hunter's famous treatise on the blood and on inflammation, which changed the face of the existing pathology, had been published in 1794. Abernethy was in the meridian of his unequalled reputation. Astley Cooper and Charles Bell were rapidly rising into eminence. Dupuytren had just been appointed to the Hotel Dieu, where his surgical ability was so long unrivalled. Laennec, to whom our art owes more than probably to any single man of either ancient or modern times, was commencing the investigations which have rendered such imperishable services to the science and practice of medicine. Cuvier was in the zenith of his fame.

The whole method of investigation had also undergone a complete change. Authority was no longer regarded as paramount. The ancients, it is true, had been long dethroned, but, in their stead, more modern masters had arisen, whose teachings had acquired a sway over the minds of physicians almost equalling that exercised by Hippocrates or Galen. Twenty years before, the celebrated Cullen related an anecdote, in a lecture which he delivered in the University of Edinburgh, which shows how the authority of Boerhaave was enough to weigh heavily on the freedom of inquiry. “My friend and patron, George Drummond (Provost of Edinburgh), came to me,” he said, “requesting seriously that I would avoid differing with Dr. Boerhaave, as he found my conduct in that respect was likely to hurt myself and the university also.” He adds, with characteristic prudence, “I promised to be cautious; and upon every occasion I spoke very respectfully of Dr. Boerhaave.” Now, with the growth of science, and with the development of new means of investigation, the received opinions were examined with a freedom and minuteness which had been before unusual, and from which results of the highest value soon flowed. Looking back on the state of knowledge at the beginning of the century, we can recognize the vast strides which have been made in every department of medicine.

Now, this very progress, of which we are justly proud, has been made a subject of reproach to the profession of medicine. The pharmacopeias of past generations have been disinterred, and the public made merry with such complex formula as the Aqua Cœlestis and the Mithridate Andromachi. The opinions, often, it must be admitted, crude and fantastic enough, of the

¹ [Dublin Quarterly Journal of Medical Science, 1868, v46, p276.]

earlier physicians, have been cited as evidence that medicine has been practised without any solid foundation for its precepts and methods. In reality, however, this only proves that the growth of medical science has been accompanied by errors and imperfections, such as are known to have occurred in abundance during the development of other branches of knowledge. The history of astronomy, of chemistry, of geology, afford us multiplied examples of speculations as baseless as those of Paracelsus or Van Helmont. Besides, it must be remembered, that physicians could not be mere curiosi naturæ—could not be content to be simply spectators of phenomena. They found themselves in the presence of formidable maladies, of devastating epidemics, and these they had to meet with the best means at their disposal. In the face of difficulties and danger, often of the most urgent character, sometimes of even appalling magnitude, they had to act with the limited knowledge which they possessed. No doubt many of their principles were erroneous, and much of their practice useless, some even mischievous, but still their knowledge was always vastly in advance of the popular notions of their day.

It is easy to point out mistakes into which they have fallen, just as it is easy to discover defects in the criminal legislation of our ancestors, in their notions of political economy, and in many of their methods of administration; but we know how incomparably better than anarchy is even an imperfect system of government; and in estimating the value to the world of the medical art of earlier times, we must bear in mind the extreme ignorance of medical subjects which was shared by the foremost intellects of their generation.

When the student of the history of medicine is wearied and disheartened by the laborious trifling and the idle discussions of his predecessors, let him turn to the pages of the most eminent contemporary authors, and learn their opinions on kindred subjects, and he will rather wonder at the acuteness and penetration of the earlier physicians. It is only by investigations of this kind that we can calculate the true position which the cultivators of medical science have held in relation to the general progress of human knowledge. It may not, accordingly, be devoid of interest, if I allude to some of the opinions on medical subjects held by several of the foremost thinkers of modern times; selecting only those philosophers who have given serious attention to questions connected with our art, and who have given deliberate expression to their views. Nor need we search for our examples among the followers of Aristotle and the ancients; we can find them in abundance among those most deeply imbued with the new methods.

Probably we could find no more typical representative of modern thought and of the spirit of modern investigation than Bacon. He, more than any man of his generation, had thoroughly broken with antiquity.

Bacon had a high idea of physic, and a genuine respect for physicians, although, according to a custom which is not altogether unknown even in the present day, he was fond of lecturing them on their shortcomings, and of giving them a good deal of perfectly well-intentioned advice.

“Medicine,” he tells us, “is a science which hath been more professed than laboured, and yet more laboured than advanced.” He advises physicians to raise their thoughts above common cures to the subject of prolonging and renewing the life of man, and he brings against them a charge, which has certainly not often been repeated, of prescribing in too simple a manner, and of not combining together a sufficient number and variety of drugs. In addition, however, to his criticisms, he has given an elaborate exposition of his own views as to the means by which life may best be prolonged and renewed. It may be interesting to touch upon some of his opinions on this subject, as an example of how a problem of this kind was dealt with at the beginning of the seventeenth century by one of the foremost intellects of modern times.

Life, according to Bacon, may be effectually prolonged by a combination of ten operations. Of these the first is,¹ “The operation upon the spirits to renew their freshness.” This is to be accomplished by various means, of which the principal is the daily use of from three to ten grains of nitre. This remedy refrigerates and condenses the spirits, and he conceives it to have been specially created for that object.

The second operation is the exclusion of the external air from the surface of the body. This is to be effected by closing as completely as possible the pores of the skin. For this purpose astringent baths are to be used, and the surface of the body smeared with oil. Passing over the intermediate operations, we come to the ninth, which is, perhaps, the most curious of the whole. It is entitled, “The operation upon the inteneration of the parts which have become dry, or the softening of the body.” It is intended to counteract the drying and hardening of the body, which occurs as age advances; and is to be effected by baths and by anointings.

“In the fable,” he informs us, “of the restoration of Pelias to youth, Medea, when she pretended to set to work, proposed to accomplish it by cutting the body of the old man to pieces, and boiling it up in a cauldron with certain drugs. Some boiling may perhaps be required for the purpose, but the cutting to pieces is unnecessary.”

The best bath, according to Bacon, is one composed of the warm, fresh blood either of man or of animals; but as this is somewhat loathsome, it may be replaced

¹ “Historia Vitae et Mortis.” In this and in the following quotations I have used, with a few slight alterations, the version of Headlam, given in the edition of Bacon’s works by Spedding, Ellis, and Heath.

by other substances of a nutritive character. The Baconian prescription for this unique bath is that it should be composed of the fatter kinds of flesh, such as beef and pork, with oysters, milk, butter, yolks of eggs, wheatmeal, and wine sweetened with sugar or honey. To these should be added salt, saffron, mastic, myrrh, and myrtle-berries.

“The operation will become far more powerful if the proposed bath (which I hold to be the principal thing) be attended by a course and order of four operations. First, before bathing, rub the body and anoint it with oil mixed with some thickening substance, that the power and moistening heat of the bath, rather than the watery part, may enter the body. Next, get into the bath, and remain there about two hours. After the bath cover the body with a plaster of mastic, myrrh, tragacanth, diapalma, and saffron, to keep in the perspiration as much as possible, till the soft matter has by degrees become solid, and keep it on for twenty-four hours or more. Lastly, after taking off the plaster, anoint the body with a mixture of oil, saffron, and salt. Renew the bath with the plaster and unction as before every fifth day, and let the process of softening the body continue for a month.”

I think it would be difficult to find anywhere a series of directions more likely to injure the health, or more directly antagonistic to sound notions about the animal economy, than those which we have quoted from the father of modern experimental philosophy.

About the same time that Bacon was announcing this discovery to the world—a discovery which was, in his eyes, so important, that he advanced the treatise containing it to an earlier place in the *Instauratio Magna*, so that no time should be lost in making it public—Harvey, then lecturer on anatomy and surgery at the College of Physicians, was announcing his immortal discovery of the circulation of the blood. Indeed, it is stated that Harvey was physician to Bacon himself, as well as to James I., and that he had formed a low estimate of Bacon’s powers, having probably judged of them from the character of his physiological speculations. “He writes philosophy like a Lord Chancellor,” Harvey is reported to have said in derision.

Physiological subjects were treated of at much length by another illustrious philosopher, Descartes, who may be regarded as standing in the same relation to modern psychology that Bacon does to modern experimental philosophy. Descartes, who was a man of spotless character, had, like Bacon, studied the means of ensuring longevity, and had arrived at the conclusion that the surest method of preserving life is not to fear death.¹ He was well acquainted with the circulation of the blood, and his advocacy of Harvey’s views contributed powerfully to bring about their acceptance throughout Europe.

He published a treatise on man, which was the fruit of fifteen years of anatomical study and observation, in which he explained his views as to the manner in which the circulation was maintained.

There is, according to Descartes,¹ a non-luminous fire contained in the pores of the substance of the heart which renders it so extremely hot that the blood on entering it becomes at once dilated, and brought to the condition of vapour. In this gaseous state it is sent to the lungs, where it is cooled and restored to the liquid state, and in this condition returned to the left side of the heart. No sooner, however, does it again enter the heart than it is again rarified by the fire contained in that organ, and in this way is driven into the arteries.

Descartes made some considerable discoveries in physics, but it is evident that his fifteen years’ study had not enabled him to much advance our knowledge of vital processes.

It is well known that the benevolent mind of Berkeley, one of the most acute of modern metaphysicians, was filled with the notion that in tar water, made by pouring a gallon of cold water upon a quart of tar, he had found a panacea for all the ills of humanity. So profoundly was he impressed with the importance of his favourite remedy, that we find him declaring:²—“As the old philosopher cried aloud from the housetop to his fellow-citizens, ‘Educate your children.’ so, I confess, if I had a situation high enough, and a voice loud enough, I would cry out to all the valetudinarians upon earth, ‘Drink tar water.’”

He even attributed to this wonderful fluid a subtle influence on the development of the intellect. “Nor is it only useful,” he says, “to the bodies of infants, it hath also a good effect on their minds, as those who drink it are observed to be remarkably forward and sprightly. Even the most heavy, lumpish, and unpromising infants appear to be much improved by it. A child there is in my neighbourhood, of fine parts, who at first seemed stupid and an idiot, but by constant use of tar water grew lively and observing, and is now noted for understanding beyond others of the same age.”

When we remember that this passage was published in 1752, when Cullen and William Hunter were teaching medicine and anatomy, we shall have no reason to doubt that, on their own ground, the physicians of the day were more than a match for the metaphysicians.

Coming to more modern times, we may select, as a final instance, the greatest speculative philosopher of Germany, the celebrated Kant. Kant had the singular misfortune to be impartially and eminently wrong, both in what he believed about medicine and in what he disbelieved. He was an enthusiastic admirer of the absurd Brunonian system, which hardly survived its birth, and of the puerilities of Beddoes; and he was strongly

¹ Au lieu de trouver le moyen de conserver la vie, j’en ai trouvé une autre plus sûr, c’est celui de ne pas craindre la mort. Œuvres de Descartes par Cousin.—Tome i., p. 112.

¹ L’Homme. Œuvres. Tome iv.

² A Letter to T. P., Esq., containing some further remarks on the virtues of tar water, and “Farther Thoughts about Tar Water.”

opposed to what has proved an inestimable blessing to the human race—the practice of vaccination.

It would not be amiss, when we are lectured by some of our contemporaries on the defects of our art, to remind them of the errors into which men greater than they have fallen when they ventured into our domain, and to counsel them to learn humility from the example of Bacon, of Descartes, of Berkeley, and of Kant.

I have adduced these instances, to which it would be easy to add many others, not with the idle notion of depreciating the labours of the great philosophers to whom I have alluded, but to show the inherent difficulties of the study of medicine, the danger of regarding the facts or generalizations derived from other sciences as adequate to its elucidation, and the absolute necessity for a minute and accurate as well as comprehensive knowledge of the phenomena of disease before venturing to even speculate upon its theory, much less to meddle with its practice.

It was acutely remarked by Bichât that pathology, the science of disease, has no exact analogue among the physical sciences. Physiology bears the same relation to living bodies that astronomy, mechanics, and the other branches of natural philosophy do to inert matter. But there is no pathology of any of the physical sciences. We cannot suppose gravitation to be variable in its operations, or chemical affinity as liable to diseased action. Nor can we conceive these forces as susceptible of being influenced by medicaments.

Accordingly the processes of disease must be studied by and for themselves, and they, as well as the modes of modifying them, and of restoring healthy action, must be made the subject of special investigation, which is to be conducted according to the general principles which govern all scientific research, but which must not be dominated by ideas derived from any other branch of inquiry.

Even as regards the impression produced on the mind, there is a marked difference between the contemplation of vital phenomena and that of the operation of the physical forces. The study of life and of its manifestations conveys the idea of tumultuous action and energy, of effort sometimes bathed, sometimes victorious, of a strife and turbulence, so to speak, compared with which the majestic regularity and unvarying precision of the physical forces seem the type of serene and immutable power.

When chemistry and physics, and anatomy and psychology, have said their last word, we are still only on the threshold of medicine, and it is from a neglect of this important truth that so many mistakes have been committed. There is no doubt that many of the ablest physicians have proposed theories which have not borne the test of subsequent investigation, but there was this important peculiarity with regard to most of these theories, that the experience and sagacity which their authors had acquired by watching the working of

diseases and of remedies saved them from falling into such disastrous errors of practice as those which we have noticed.

It has been stated with regard to Sydenham that while his system was very often bad, his practice was generally good. Probably at the present day our practice is in advance of our theory. We all allow ourselves a certain latitude in speculation, but we hold fast by the practical facts which have been gained to us by centuries of observation, and which are none the less valuable because they are often purely empirical. I believe no man living can fully explain why and how opium acts, and yet every physician knows its effect, and how to get from it the maximum effect with the minimum of risk in cases where he considers it to be useful.

Now when we find that the leaders of thought and of progress in their generation fell into the egregious blunders to which we have adverted, we can form some faint conception of the chaotic condition in which the notions of the uneducated mass of the people must have been with regard to medical subjects. Even now, with the vastly greater facilities for the acquisition of knowledge which the spread of education has afforded, we are all aware of the great number of popular errors which we have occasionally to combat, of the vigour and intensity of popular prejudices, and, at the same time, of how easily a large portion of the world can be dazzled by any specious or confident pretender. When we reflect on homeopathy and hydropathy; when we think of the hundred delusions not more baseless, although generally infinitely more mischievous, which have flourished and been forgotten, we see with what flimsy theories large numbers of the community can be satisfied. And when we think of the cancer-curiers, and of the consumption-curiers of the countless knaves who prey upon other forms of human infirmity, we can form some notion of the enormous value of our profession to the world, if it possessed merely the negative merit of protecting our fellow-creatures from these cruel, ignorant, and rapacious charlatans.

I should be sorry, however, to be supposed to throw any imputation on the motives of many of those who are incredulous regarding the value of the art of medicine. No doubt in numerous instances this incredulity is the result of genuine conviction, in others the fruit of an imagination too active and soaring to be trammelled by mere facts. Many have “been driven, by strong benevolence of soul,” far beyond the regions of common sense and of daily experience. Not very many years have elapsed since I entered upon the study of medicine, and yet during that period, hardly exceeding three lustres, I have witnessed the rise and fall of several all but infallible remedies for various diseases. I have read several publications, before which, in the opinion of their authors, the whole structure of medicine was destined to fall as speedily as the walls of Jericho did before the trumpets of Joshua. I have been solemnly advised,

may warned, to devote my attention to as many systems of cure as would have given me full occupation in their investigation, could I have looked forward to years as numerous as those of “the many-wintered crow,” or, as might be hoped for from Bacon’s bath, were it as efficacious in producing longevity as it is undeniably disgusting.

The fact is, that while with our present knowledge no great generalization is as yet possible, we have ample scope for the most far-reaching and penetrating intellect in the work which lies at our hand.

A distinguished writer has attributed to the study of medical science an important influence in the development and cultivation of one of the most remarkable intellects of modern times. “No science could have been chosen more happily,” says Dugald Stewart, “to prepare such a mind as that of Locke for the prosecution of those speculations which have immortalized his name; the complicated and fugitive, and often equivocal phenomena of disease requiring in the observer a far greater portion of discriminating sagacity than those of physics, properly so called; resembling, in this respect, much more nearly, the phenomena about which metaphysics, ethics, and politics are conversant.”¹

Even to ascertain what the disease is under which his patient labours, a physician must have an exact knowledge of healthy structure and function, so as to recognize the character and extent of the deviations from them; he must be familiar with the vast range of diseases which have been known to occur, so as to be aware of what is possible; he must possess delicate and experienced tact to be able to ascertain and elicit the symptoms which are present; and as the facts upon which his conclusions must be based are often incomplete, sometimes apparently contradictory, occasionally even wilfully withheld from him, he must possess a power of nice discrimination, and a thoroughly trained logical faculty, to be able to arrive at a correct conclusion as to what the disease is most likely to be, and how far he is warranted in acting on the probability so arrived at. It is essential, also, that his knowledge should be so thorough as to be always and in every emergency at once available for use, a requirement which necessitates such a familiarity with both principles and details as is only to be gained by long and earnest study.

All of us have had experience of the immense amount of time and patience necessary to gain a proper knowledge of human anatomy. We know the wide field embraced by physiology and pathology, by medicine and surgery, and what labour it requires to traverse it with anything approaching completeness. We know the amount of time and attention which it is necessary to devote to the acquisition in the wards of an hospital of some practical familiarity with the daily

duties of the life of a medical practitioner; and, reflecting on this, we see how scanty, in reality, is the period allotted to professional studies, and how impossible it is to curtail it by giving up any considerable portion of it to other than professional subjects. We see, too, how essential it is that every one who attempts to master this vast department of human knowledge should come to its study with his reasoning powers, as far as possible, already disciplined, with his faculties of attention, of abstraction, of comparison, and the like, already exercised and sharpened by a sound and well-directed preliminary education. To such students the acquisition of knowledge is easy and delightful, and from such students we may fairly expect additions hereafter to our knowledge of sterling and solid value.

Within the last few years, and in a great degree, it must be owned, in consequence of the action of the General Council of Medical Education, a considerable advance has been made towards the establishment of a better and more comprehensive standard of general and professional education. Few questions are of greater public importance than this; for everything which tends to increase the efficiency of the members of the medical profession has a direct and obvious bearing on the well-being of the community in which they are to exercise their art.

Even, however, among some of the ablest and most enlightened advocates of improvements in our present system, there are signs of a tendency to attach undue importance to those branches of learning which are high in public estimation, and of which the cultivation may be regarded as favourable to the maintenance and advancement of the prestige and the social position of the profession.

I cannot, for example, attribute the vigorous efforts which have been made to establish the Greek language as an essential part of the preliminary education of medical students altogether to a conviction of its importance in promoting the ultimate ends of medical education. A superficial acquaintance with Greek is, it would seem to me, comparatively worthless; and any large or thorough knowledge of the masterpieces of its poetry, philosophy, or history, is, as regards the medical student, practically unattainable—indeed, is practically unattained by the immense majority of those who have received what is ordinarily understood to be a liberal education. The arguments which are employed by the advocates of Greek seem to take for granted that the ordinary student will be enabled to at least read the great works of its literature with ease, and that he will derive a high kind of gratification, as well as of æsthetic culture, from the exercise of this power. In addition to this, he is expected to become better acquainted with the principles of universal grammar and with philology and to obtain a more complete mastery over the resources of his own language; and these advantages, it is said, will be cheaply purchased by the admittedly irk-

¹ Dissertation of the Progress of Philosophy since the Revival of Letters.

some and protracted exertions necessary to master the elements of the language.

I am quite willing to acknowledge that a large and thorough knowledge of classical languages and literature is an indispensable element in the highest culture; and if the circumstances of the country or the position of the profession warranted us in demanding this knowledge from every aspirant to the rank of a medical student, I should welcome any effort in the direction of a result so desirable. But I do not think that the preparation for an ordinary matriculation examination has any considerable effect in this direction. The beauty and perfection of form of the ancient masterpieces can only be felt when the language in which they are contained has become so familiar to us that no effort on our part is necessary to enable us to understand the meaning of the words, and when we have attained to some comprehension of ancient modes of thought and feeling. That this is the result of a partial study of Greek is not likely to be asserted by any one who is familiar with the facts. I think that a more thorough knowledge of Latin, if, in addition the student were required to be acquainted with a modern language, would suffice amply for the grammatical training, and for the æsthetic culture, which are, no doubt, indispensable parts of high education.

It would not be difficult to show to any one, whose mind is not biased by the traditional reverence for classical learning which has imbued so profoundly most of our theories of education, that the study either of the French or of the German language is, as a means of educating the critical faculties, not very much inferior to that of Greek; while as an end—as conferring the power of completely and readily understanding the works written in either of these two modern languages—compared with a similar mastery of the ancient tongue, the balance of advantage is so vastly against the Greek as to preclude the possibility of any serious comparison. In fact, with the exception of its value in enabling the student to more readily understand scientific terminology, Greek may be regarded as an intellectual luxury; and it may be worth observing that in medicine we have really no scientific terminology, in the proper sense of the words. Our names of diseases do not express their systematic relations, as the nomenclature of chemistry does with respect to the substances with which that science is concerned, and, indeed, in the present state of our knowledge, it is highly desirable that we should not attempt the formation of a systematic terminology, so that on this ground also Greek cannot be regarded as necessary.

Again, a more extended and more fruitful use might be made of the valuable means of training which the natural and experimental sciences afford. The study of these sciences tends to develop and strengthen precisely those powers and faculties which are constantly called into requisition during the exigencies of professional

life. Exact observation of facts, careful reasoning, and rigorous scientific method are derived almost of necessity from a sound and judicious training in these sciences. It is essential, however, to bear constantly in mind, in the consideration of this important question, that whatever be the means employed for the purpose, the education of the faculties, in the true and limited sense of the word education, is the important thing. Without this even considerable erudition or extensive knowledge of the facts of natural science will be of little use to the student; nay, may even overburden his undeveloped intellect—

Like Saul's plate armour on the shepherd boy,
Encumbering and not arming him.

With regard to the question of the granting of medical degrees, the Council has done good service. It is probable, as has been observed by Adam Smith, that no examination ever has been, or ever can be, devised, which will give an absolute security to the public that he who has passed it is thoroughly competent to practise medicine. That degrees and diplomas have sometimes been conferred on men who were neither wise nor judicious is probably no secret either in the profession or out of it. But every effort should be made in the interest of justice and of humanity, that as far as is possible a degree should be a *bonâ fide* evidence at least of the acquirements of its possessor. It is quite clear, accordingly, that no competition should be permitted between the corporations who possess the privilege of granting them. No body should be allowed to attract candidates for its qualification by a less extended curriculum, or a less strict and searching examination than those of its rivals. This would at once and finally extinguish the artificial distinction between medical and surgical qualification, which has been a fertile source of evil to the profession.

And now, gentlemen, laying aside the consideration of questions which are specially interesting to ourselves, and regarding the wider one of the position of medicine throughout the world, I think we have ample grounds for congratulation and hope. Never have inquiries and investigations been prosecuted before with such wealth of scientific appliances, or over so many countries, or by men of such different culture, or under circumstances of so great diversity. Never were intellects of a higher kind engaged in the study of our art. And, what is still more hopeful, we find that with much observation there is little theorizing. Men are now content to proceed upon the solid ground of experience and fact, anxious rather to

“Lay great bases for eternity,”

than to erect unsubstantial and unenduring fabrics of speculation.

Looking forward to the future of our art, I think of it as going onward in sedulous, intelligent, honest investigation of the myriad varieties of the action and suffering of the human body; in the unceasing search after

Ulster Medical Society
Session 1868–1869
President James Cuming

the means by which disease may be lightened or removed, proceeding slowly, it may be, but always on the solid basis of patient, unwearied observation, un-
hasting, but also unresting.

I think of it, not as quickened by higher motives or directed towards nobler aims than now, for humanity and benevolence are of the essence of the profession of medicine; but as ever gaining truer conceptions of the processes of health and of disease, and deeper insight into their nature; as laying broad and deep the foundations of a structure of knowledge from which, in “an ampler ether, a diviner air,” wider views of life and of its manifestations may be obtained.

I think of the conditions of health becoming defined; of the seminal principles of disease becoming recognized; of some medical Newton of the future unveiling for us the mystery of vitality; and, finally, of the noblest and crowning triumph of our art, in the discovery of better, surer, and wider means of preventing, mitigating, or curing disease.

“So from the root
Springs lighter the green stalk, from thence the
leaves
More æry; last, the bright consummate flower”

Dr. Reade moved that the best thanks of the company present be given to the President for his very eloquent address, seconded by Dr. McGee and carried unanimously.

Moved by Dr. Whitaker and seconded by Dr. Thomas Reade and carried unanimously that the President allow the address to be printed.

James Cuming M.D

[Undated]

Present, Dr. Cuming in the chair, Drs. Thomas Reade, Berry, J. Walton Browne and Hill.

The minutes of former meeting having been read and confirmed, as none of the gentleman who were to read cases were present the meeting was adjourned.

James Cuming M.D

521¹ Notice of meeting on 7th December 1868
The Third Meeting of the Winter Session will be held in the Library, General Hospital, on Monday Evening next, 7th inst., at Half-past Seven o'clock.

Business.

Dr. Murney will give the particulars of a case of Fracture of the Spine, and exhibit injured parts.

Dr. Mac Cormac will give a short account of two cases of Ovariectomy, and exhibit the tumours extirpated in each instance.

Mr. Johnston will give the details of a case of Carotid Aneurism, and exhibit the morbid specimen.

(By order of the Council),

John Moore, M.D.,
James Hill, M.D.,
Honorary Secretaries.

December 5, 1868.

Ulster Medical Society, December 7th 1868

Present, Dr. Cuming in the chair, Drs. Stewart, Murney, Pirrie, William MacCormac, Wales, Porter, McCrea, David Johnston, Core, J. Walton Browne, Fagan, H. M. Johnston, Messrs. Moore and Hill.

The minutes of the former meeting having been read and confirmed, Dr. Murney read notes of a case of fracture through the laminæ of the 4th cervical vertebra. The man lived 32 hours and the case was adduced as an instance where had the fracture occurred a little further out so as to damage the inter-vertebral foraminæ death would have been instantaneous. In this case trephining which has been suggested in fracture of the vertebræ would have been of no use whatever, in fact it might have hastened death.

Dr. MacCormac then gave the particulars of two cases of ovariectomy and exhibited the parts removed. In introducing the subject he gave a most interesting historical sketch of the operation. In the former case wire ligature of the pedicle was resorted to; in the latter the clamp was used.

Dr. MacCormac could not help thinking that the use of the ligature in the first case had something to do with the death. Both cases ended fatally.

Dr. Pirrie was sure every member of the Society would sympathise with Dr. MacCormac in the untoward result.

After some further observations from different members, Dr. H. M. Johnston read notes of a case of aneurism which had been rapidly fatal.

Dr. Murney then read notes of a case of fracture of the skull which terminated fatally in about 16 hours.

James Cuming (Chairman)

Ulster Medical Society, December 21st

Present, Dr. Cuming the President in the chair, Drs. Murney, Wales, William MacCormac, Fagan, Berry, H. Brown, Thomas Reade, D. Moore, A. M. Porter, John Moore and Hill.

Dr. Murney read notes of a case of hernia which ended fatally. It was peculiar in this respect that though there was a very tight stricture there was entire absence of any urgent symptoms. The man was 60 years of age and the rupture existed from boyhood. Fifteen months ago the hernia came down and had to be returned under chloroform. The pulse never rose above 76 either before or after the operation, there was no tenderness and hardly any vomiting. On

¹ [Item 522 is identical.]

P.M. examination a considerable quantity of bloody serum came from the wound and the bowels were glued together by recent lymph. He showed the recent parts.

Dr. William MacCormac then read notes of a case of hernia which was remarkable for the urgency of the symptoms without the hernial tumour being either tense or tender. It was that of an old woman about 70 years of age who for the last 10 years at least had been troubled with a rupture. It had never caused much inconvenience but never wholly disappeared. She was admitted to hospital on the 18th December and stated that at about 2a.m. she had been suddenly roused from sleep by sickness and pain and enlargement of the tumour. Before coming to hospital a medical man had tried to reduce the hernia. When seen she appeared to be in a state of collapse—the surface was cold—face pinched—pulse small, quick, weak. She had also well-marked epigastric pain which troubled her even after the operation. There was a tumour the size of a large orange in the right inguinal region but it was neither tender nor tense. Although the strangulation had not existed long, yet as the symptoms were urgent it was deemed right to operate at once. This was done in the usual way. Beneath the hernia a small knuckle of intestine quite black was observed. The stricture was very tight. The omentum adhered largely to the sac thus accounting for the tumour never wholly disappearing. She never rallied from the state of prostration in which she was when admitted but died on the following Sunday. Immediately after the operation she had three free evacuations from the bowels. She was ordered opiates.

On P.M. examination the bowels were found congested but there was no serum or lymph. There was, however, a large clot of effusion beneath the peritoneal covering of the stomach along the lesser curvature which Dr. MacCormac asked the President to describe.

The President said that when Dr. MacCormac asked him to see the stomach he thought it well worthy of investigation and accordingly he had it very carefully dissected. On the outside was found a large mass of extravasated blood and on careful examination of the parts, a small aneurism was found on the splenic artery. This at once suggested that the extravasation might be from an aneurism of the gastric artery. The only possible explanation is that the excessive straining and vomiting caused rupture. A small opening was found and it is purposed to examine it microscopically to ascertain if it be recent.¹

Dr. David Moore thought that the rupture had probably taken place before admission thus causing the shock for the state of the bowel did not appear to be such as to give rise to so urgent symptoms.

Dr. Murney thought that atheroma was pretty general throughout the arterial system—possibly other hæmorrhages may have occurred.

The President then asked if any one present had seen such a case when Dr. Bartley said he had once seen a man who appeared to be suffering from internal hæmorrhage. There was increasing debility and death occurred in three days. Blood was found in the peritoneum but although all the vessels were closely examined the source could not be ascertained.

Dr. William MacCormac then exhibited a tumour of the tibia which he had removed from a patient 21 years of age. He had been in good health till 14 months previously when thickening commenced on the outside of the knee. On admission to hospital he had an irregular lobed tumour involving the upper two-thirds of the right leg. It was 26 inches in circumference while the thigh above the knee was only 13 inches. It had an elastic feel with an obscure sense of fluctuation and had a dull aching pain and the lad presented altogether a cachectic appearance. It was considered to be a medullary cancer and accordingly the limb was amputated. Till shortly before admission there had been no œdema of the foot and the movement of the knee joint had been perfect.

Lister's carbolic oil was used for a dressing and complete union occurred in a very few days.¹

As the ordinary time for the meeting had been already exceeded it was moved by Dr. Murney, seconded by Dr. John Moore that the President's communication regarding the sphygmograph be postponed.

James Cuming M.D

Ulster Medical Society, January 4th 1869

Present, Dr. Cuming (the President) in the chair, Drs. J. W. Smith, J. W. Browne, James Moore, Rea, McWilliam, B. Smyth, H. S. Purdon, Mr. Berry, and Dr. Hill.

Dr. Cuming exhibited and described Marey's sphygmograph and took tracings of the radial pulse from different patients.

Dr. H. P. Rea asked what the utility of it was expected to be. Dr. Cuming said that till Physiologists had definitely determined the cause of the pulse it would not be of much service, but ultimately he had no doubt it would be of great benefit.

Dr. James Moore then shewed a tumour which he had removed being the third from the same lady. The first weighed about 7 pounds and was of slow growth. It was removed about 3½ years ago. The second was likewise perfectly removed about 2½ years ago. This one commenced about 3-4 months ago and its growth has been comparatively rapid. Though the first was a perfectly innocent growth, he had grave

¹ [See page 1127.]

¹ [See page 1136 for subsequent history.]

doubts about this one, and feared a similar or more noxious tumour would soon return.¹

Ulster Medical Society, February 1st 1869

Present, Dr. Cuming (President) in the chair, Drs. Dill, William MacCormac, McWilliam, Porter, John Moore, J. W. Browne and Mr. Berry.

Dr. Cuming exhibited recent parts in a case of acute peri- and endo-carditis.

Dr. John Moore read notes on 7 cases of puerperal convulsions.

(Signed) James Cuming
M.D

Ulster Medical Society, March 1st

Present, Dr. Cuming the President in the chair, Drs. Gribbin, A. Porter, Fagan, Browne, John Moore, and McWilliam.

Dr. Fagan read a paper on a case of hydroureter.

Dr. John Moore read notes of a case of meningitis.
James Cuming

24th March 1869

A Special Meeting of the Society was held for the purpose of taking into consideration Dr. Brady's Bill for the Superannuation of Dispensary Medical Officers, which is at present before Parliament.

The President in the chair. Members present, Drs. James Moore, McCrea, Whitaker, David Moore, H. Brown and John Moore.

The following resolutions were unanimously agreed to.

First Resolution. Moved by Dr. James Moore and Seconded by Dr. Whitaker That ...

Seconded Resolution. Moved by Dr. John Moore, Seconded by Dr. H. Brown That ...

5th April 1869

The President in the chair. Members present, Drs. Drennan, Thomas Reade, William MacCormac, H. Brown, Wales, David Johnston, James Smith, Stewart, Fagan, Porter and John Moore.

Dr. Drennan moved in feeling terms the following resolution which was seconded by Dr. Stewart and unanimously agreed to:

That at this our first meeting since the death of Dr. Patterson we feel called on to express our deep respect for the loss this Society has sustained by his demise and to record the respect in which we hold his memory as one of its most valuable members. In the Ulster Medical Society and proceeding ones of like kind we always found in him an active, intelligent and friendly counsellor and cooperator whilst by the general community he was recognised as a useful citizen and a man of stainless integrity.

We would hope that this our unanimous expression of esteem for her husband's character may afford some slight solace to his widow in her present great affliction.

The Secretary was instructed to convey to Mrs Patterson a copy of the Resolution.

COMPILER'S NOTE

The following two papers were published immediately before the President's report of rare spinal disease. They are not to be found in the minutes and hence have been inserted here.

Aneurism of the Coronary Artery of the Stomach.

Paper:¹ Dr. Cuming exhibited the stomach, spleen, and portion of the peritoneum of a patient who had been operated on for strangulated hernia by his colleague, Dr. William MacCormac.² The patient, a female, aged sixty, was almost moribund on admission into hospital, and died soon after the operation. She had complained of severe pain in the epigastrium for some days before death. When making the post mortem, Dr. MacCormac had found a dark mass above the lesser curvature of the stomach between the layers of the peritoneum. On examining the specimen which had been placed in his hands, Dr. Cuming found that the mass consisted of coagulated blood, which had been furnished by the rupture of a small aneurism, situated on a large branch of the coronary artery of the stomach proceeding towards the cardiac end of that viscus.

The blood, which was about three or four ounces in amount, was contained between the folds of the lesser omentum.

Loss of Speech in Typhoid Fever.

Paper:³ DR. ROSS read a paper on the subject of typhoid fever, its history and symptoms, from which we extract the following interesting cases:—

CASE I.—A young lady, aged eleven years, born in India, was attended by me for typhoid fever in the early part of 1868. The enteric affection was very severe—diarrhea, melæna to a large amount, and extreme tympanitis. She was conscious, put out her tongue when required, and took her food and stimulants well. Her pupils were remarkably dilated, but the unusual phenomenon in her case was that for three weeks she was unable to speak a single word, and even after this prolonged period she only very slowly recovered her speech. She got quite well in about four months, but the case was very tedious and very unmanageable.

CASE II.—A female, aged eighteen, passed through a very severe attack of typhoid fever under my care. The complications in the form of bronchitis and pneumonia and diarræa and tympanitis were most intractable and

¹ [See page 1137 for further history of probably the same patient.]

¹ [Dublin Quarterly Journal of Medical Science, 1869, v47, p469.]

² [See page 1126.]

³ [Dublin Quarterly Journal of Medical Science, 1869, v47, p470.]

tedious. They had, however, yielded to treatment, and we were in hopes that we had gotten our patient, so to say, out of the wood, though in a very prostrated and emaciated condition. When suddenly, without any previous warning, she was seized with right hemiplegia with relaxed muscles and loss of speech. After weeks of careful nursing, nutritious diet in the fluid form with wine and chalybeates from the first appearance of the palsy, she was able to speak, but at first only in the simplest monosyllables. Muscular power was slowly regained, and now, ten months after her illness, she is able to walk very well, but she has only partial use of her right hand and arm.

What was the cause of the hemiplegia in this young girl? I account for it in this way: the blood supplied to the brain was vitiated and impoverished; cerebral nutrition was impaired. Then followed softening of the brain, and immediately antecedent to the paralysis rupture of nerve fibres.

The President introduced a patient and gave a most interesting history of his case which was that of a rare form of spinal disease.

Paper:¹ B. M., aged 40, pork-cutter. Healthy and vigorous man. Had usually once a-year a drinking-bout of about a fortnight's duration, but was temperate in the intervals. Had been drinking for nearly a fortnight, when he observed on a cold evening in the beginning of May, 1867, when driving on an outside jaunting car, that his hands had become numb and white as far as the second joints of the fingers. When he reached home he found that he was unable to lift a cup, although he could lift anything which he could grasp in his hand. On the next day he had a good deal of spirits, and went to the seaside when he fell asleep on an exposed wall. On awaking he was chilly and shivered, and he found the numbness increased. On the following day when on the street he found that he had some difficulty in walking, and went home to bed. On the succeeding morning he found on getting out of bed that he could not stand. He dressed, however, and was helped on a car and went to the house of a medical man.

I saw him for the first time nearly a week after. He was then totally devoid of power of voluntary motion below the neck, except that he could impart a slight movement to the right shoulder. His sensation was perfect. There was no abnormal sensibility, and no pain or uneasiness. Deglutition and articulation were perfect, but respiration was greatly embarrassed, mainly by an accumulation of mucus in the larger tubes, which he found it impossible to get rid of, as he was unable to cough.

No involuntary movements could be excited by pinching or tickling. He was covered with a profuse drenching perspiration which formed a prominent symptom throughout the case. Pulse 126; tongue furred,

but moist, he could relieve the bladder and the bowels. I found it impossible to make any observation regarding the presence of tenderness, as he had been blistered from the nucha along the whole spine, besides having a large blister on the chest, and being profusely salivated. I subsequently found that no tenderness existed, and the blisters, contrary to my expectation, as the patient could only lie on the back, healed rapidly and well, and neither then nor at any period during his illness had he a bedsore. He slept little, and badly; urine examined and found normal. The prognosis was of course unfavourable, and I ordered merely two grain doses of iodide of potassium every six hours. To my surprise I found him alive on the following day. For some days there was very little change, except that the respiration became gradually easier. He was still, however, in such a condition that when turned on the right side the distress became so great and urgent that he had to be at once laid on his back.

From this period a progressive change in his symptoms occurred. Gradually he began to suffer from involuntary and spasmodic contractions of the muscles of the lower extremities occurring occasionally, and from darting pains in the lower limbs. The power of motion gradually and slowly returned; at the end of three months he was able to get out of bed, and his progress has since gone on slowly, but uninterruptedly towards the regaining of his muscular power. His first attempt at motion caused him a good deal of pain. His general health always continued during his protracted confinement, excellent, and no bedsores formed. At present, nearly two years after the commencement of his illness, he walks slowly but steadily; he is easily upset by an obstacle, but he can walk about for a considerable period with occasional rests. His hands present a well-marked example of the "main en griffe" of Duchenne, and he experiences much difficulty in flexing the metacarpophalangeal articulations; indeed, he can only do this to a very limited extent. The muscles though wasted preserve a moderate bulk, and he is able to shave, although with much difficulty, and very slowly. There is a slight tendency to constipation, and urination is a little slow at the commencement, but he is otherwise in excellent health, and is undoubtedly steadily improving, he is not at present under any medical treatment whatever.

I do not feel myself able to pronounce definitely on the nature of the spinal lesion which existed, and of which traces are still present, but I have regarded the case as one of sufficient interest to be recorded. I am disposed to consider that the affection was mainly, if not entirely of a congestive character. The combination of symptoms present consisted of complete paralysis of a paraplegic form, no tingling, no increased reflex excitability, no pain or tenderness, power over the bladder, and rectum, profuse drenching perspiration, appetite and digestion normal, sleep imperfect, and dysp-

¹ [Dublin Quarterly Journal of Medical Science, 1869, v47, p471.]

nea from inability to cough. Subsequently pain, spasms of the lower limbs, peculiar deformity of hands.

Dr. William MacCormac exhibited the left half of the lower maxilla which he had removed from a young woman for osteosarcoma. The case done well.

Paper:¹ The operation for the removal of one-half the inferior maxilla is a surgical procedure both difficult to perform, and of comparatively rare occurrence. It is only in more recent times, indeed, that patients afflicted with disease of the lower jaw received surgical aid in any shape. And to British surgery is due the merit of the innovation, Mr. Anthony White having performed resection of a portion of the lower jaw in 1801, several years before Dupuytren or Cusack commenced the series of brilliant successes which established the operation as a sound and safe surgical proceeding. The number and size of the vessels involved render the risk from hemorrhage, both immediate and consecutive, very great—so much so that many amongst the earlier operators recommended the ligature of the carotid as a preliminary step in the operation, Probably in no operation of the kind is an artery of the importance of the internal maxillary placed in such dangerous proximity to the knife, nor could there be one more difficult to secure should it be wounded. Without further preface I will give a short account of a case in which I performed this operation.

Ellen M'Cappin, aged twenty, a healthy country girl, was admitted recently to the General Hospital under my care. About two years ago, not having experienced any previous illness, she noticed that the left lower jaw was swollen. From this date it continued to increase gradually and without pain.

On examination the left side of the lower jaw from the bicuspid teeth to the sigmoid notch is found to be involved in a very hard irregular tumour. It is felt on both sides of the maxilla but projects more externally, where three distinct prominences, continuous with each other, can be distinguished. One of extreme hardness covers the ascending ramus as high as the notch; another, the size of a small hen's egg, also very hard, projects beneath the body of the bone, whilst the third, elastic and comparatively soft, involves the whole of the alveolar border. The tip of the coronoid process, the angle of the jaw, and articulating head of the bone, alone appear uninvaded by the growth. The third or wisdom tooth, never made its appearance. The second molar got loose, and was extracted some time ago; and the first molar I removed myself, thinking, possibly, it might thus give exit to fluid from the elastic tumour on the alveolus. As none came away, the cystic nature of the growth was excluded from consideration.

The diagnosis before operation as to whether this tumour might be fibrous, cartilaginous, or myeloid, was

almost impossible. I thought it probably fibrous or fibro-cartilaginous, with deposit of bone, judging from its extreme hardness. The discrimination of the nature of the growth was, however, of no practical importance to the patient, as there could be no doubt as to the necessity of the removal of the affected portion of the jaw, which I decided to disarticulate.

The patient having first been fully chloroformed, the first bicuspid tooth on the affected side was extracted, as in this situation, it was decided to divide the bone. A nearly rectangular incision was then made commencing opposite the lobe of the ear, proceeding downwards to the angle, and thence across the body to within half an inch of the symphysis. All the soft parts down to the bone were divided in this first cut. The facial artery and a mental artery being wounded, were at once taken up and tied at both ends. The flap thus formed was carefully dissected up, the knife being kept close to the bone, and in this way, and also by having commenced the vertical incision so low down, the parotid duct, and the chief branches of the facial nerve, escaped injury. The outer surface of the tumour being now thoroughly exposed, the jaw was cleared at the point of section in front of the mass, and divided with a small saw cutting from below upwards. The operator to do this must stand behind the patient, the head being thrown back, and the section is thus effected with great ease, as the lower jaw is steadied against the upper, and the soft parts can readily be held aside, and incur no such risk of injury as when the end of the saw is inside the mouth. When the bone was nearly cut through, a bone forceps completed the separation by dividing the alveolar process.

The jaw was now everted, and the edge of the knife being kept scrupulously close to the bone, the deep fasciæ and the mylohyoid and internal pterygoid muscles were dissected off the inner surface. By depressing the jaw forcibly the attachments of the temporal muscle were brought into view and severed; then the bone was rotated outwards, and the external pterygoid muscle divided with the utmost caution. The joint was opened in front, its capsular and other ligaments severed, and the tumour removed. Only two other small arteries required ligature, and three ounces of blood were certainly not lost during the operation. The influence of the chloroform was maintained throughout. The wound having first been bathed with carbolic lotion, was closed with six interrupted sutures, inserted through the whole thickness of the cheek. Carbolic dressings were applied, but no plugs of lint introduced internally, which serve, I think, no useful purpose, form a nidus for the collection of foul discharges, and are painful and difficult to remove. The only instruments I had occasion to use during the course of the operation were a scalpel, saw, and cutting forceps, and from the first incision to the insertion of the last suture, and application of the dressings, the time occupied was exactly twenty-four

¹ [Dublin Quarterly Journal of Medical Science, 1869, v47, p472.]

minutes. The after-progress of the case proved very satisfactory. The wound united by adhesion. There was nothing complained of by the patient but soreness in the throat, which lasted only two days. One week after the operation she sat up perfectly convalescent, all the stitches and ligatures removed, and the wound almost quite healed. The small amount of deformity is very surprising, and the situation of the incision and cicatrix are quite invisible when the patient is looked at in front, in fact it would be difficult for a stranger to tell from which side the jaw had been excised. There is now no retraction of the remaining portion of the maxilla, and the inferior incisors correspond exactly to those in the upper jaw. On making a section of the jaw the tumour is seen to spring from its interior, distending the bone in all directions, somewhat irregularly, or more to the outer side, as before mentioned. It is of a uniform white colour, dense, and firm to the touch, and contained spicula of bone. In the centre of it is a small tooth, which is the missing wisdom tooth. To the unaided eye its characters are those of a fibroid growth, and the microscope shows that it contains fibres and elongated nucleated cells. There is every reason to hope that the disease, having been completely extirpated, will not return.

Dr. James Smith detailed the history of a case of heart disease which had terminated fatally.

Ulster Medical Society, 19th April 1869

Present, Dr. Cuming (the President) in the chair, Drs. J. W. T. Smith, Browne, Seaton Reid, Thomas Reade, William MacCormac, McWilliam, J. Walton Browne, Ross and Hill.

It was moved by Dr. Seaton Reid, seconded and agreed to that Drs. Brice Smyth, H. S. Purdon and Hill form a committee to examine and report on the state of the library at the Annual Meeting.

Dr. Smith then [read] notes of a case of abscess of the lung.

Paper:¹ Mr. E. had occasionally consulted me during the last ten years. With the exception of an attack of acute gout in one foot six years before, his ailments had been of a very trivial kind.

He was forty-four years of age, of middle height, well built, and possessed great physical strength. He was of active habits, and fond of field sports. I saw him on 29th August, 1868. He had been ill for eight days with cough and occasional chills; was feverish and restless at night, and unable to sleep in consequence of the hard frequent cough; his appetite was bad, his pulse 100, and his tongue was much coated. A careful examination of his chest could detect no cause for his cough; the respiration, although somewhat quickened, was perfectly natural, and his heart sounds were healthy.

When looking into his throat to see if there was any cause of irritation there, he coughed, and I immediately felt a gangrenous odour. He himself had felt it occasionally during the two days when coughing. I concluded that he had an abscess of the lung, and explained so to him.

I visited him next day, and saw the expectoration of the previous night—about three ounces of dirty yellow-coloured pus mixed with blood. His chest was again carefully examined, but nothing abnormal was heard. It was not till the 2nd September, five days after I first saw him, that there were any stethoscopic signs of disease. On this day pleuritic friction sound and crepitus were heard about one and a-half inches below left nipple. During the next ten days these sounds gradually extended upwards, and on the 15th were audible over the whole front of the left lung to within two inches of the clavicle. The expectoration at night had increased to eight or ten ounces, and was often very offensive; it varied in colour from greenish yellow to grey, and was sometimes mixed with a good deal of blood.

On the 20th Dr. Seaton Reid saw him in consultation. He concurred in my opinion of the case, and recommended small doses of turpentine and ether, in addition to the quinine and mineral acids previously ordered. At the end of a fortnight the stomach became irritable, and the medicines were discontinued; friction sound and coarse crepitation were now also heard below left axilla. On the 6th October there was a slight attack of gout in one foot, which disappeared in a few days. On the 15th he was suddenly seized with an acute pain in the left side; he was unable to lie down; his respirations very frequent; pulse 130. He was relieved by full opiates, and in a day or two loud friction sounds were heard at the back, from the spine of the scapula downwards. He had been now ill eight weeks, had lost much flesh, and the expectoration had not diminished. He was ordered quinine and tincture of muriate of iron every four hours. From this time a gradual amendment took place, and in four weeks he was able to be removed to the country. Here he steadily improved in health, and gained flesh. Cod liver oil had been added to the quinine and iron.

He returned to town about the middle of December, feeling almost well; he was within a few pounds of his usual weight, the cough was almost gone, and the expectoration was reduced to about a drachm in the night; except that a few clicks were heard on full inspiration in front of the left lung, and that it was somewhat less resonant, all abnormal sounds had disappeared.

About Christmas I met him in the street; he appeared to be, and said he felt, quite well. On Tuesday, 5th January, having felt well and walked out the day before, he had a severe rigor, and vomited. I saw him soon after; his face was flushed and heavy, pulse 120, no change in the lung since last examination. On the

¹ [Dublin Quarterly Journal of Medical Science, 1869, v48, p666.]

8th there was a slight puffiness at the outer angle of left eye, and he could not move in bed from pain in the lower part of his back and right hip. On the following day there was some fulness here which gradually increased, and extended down the thigh. On the 12th free incisions were made behind the trochanter and on the outside of the thigh, which gave exit to a quantity of intolerably fetid pus, mixed with bubbles of air. On the 14th he was seized with severe pain below the right nipple, and friction sounds were heard here. The swelling at left eye was opened, and discharged an ounce of pus. He was quite sensible, but in a state of great prostration; he had profuse sweats, and his breath had a sickly odour of pus. On the next day there was evidence of matter in the ankle-joint. He lingered till the 18th, when death terminated his sufferings.

Although an examination of the body was not obtained, there is, I think, little doubt, that the case was one of deep-seated abscess of the left lung. The course of the disease, the gradual development of the signs of pleuro-pneumonia limited to one lung, and the peculiar character of the expectoration, cannot well lead to any other conclusion. It is worthy of note, that although a careful examination of his chest was made daily, no physical sign of disease was heard till five days after he was first seen. The termination of the case was very unexpected. The supervention of pyemia in such a case must be of rare occurrence, especially when restoration to health seems almost assured.

After some remarks on the case by Dr. Seaton Reid, who had seen the man, by Dr. Thomas Reade and the President, the President proceeded to give an account of the case of the late Dr. Patterson.

Dr. Browne then read the particulars of a case of acute necrosis of the thigh requiring amputation.

It was then proposed by Dr. Hill, and seconded by Dr. Smith that Reynolds System of Medicine be added to the library.

J. W. T. Smith, President

Annual Meeting, 10th May 1869

Present, Dr. Cuming (President) in the chair, Drs. Stewart, J. W. T. Smith, William MacCormac, Whitaker, Murney, Harkin, David Johnston, John Moore, J. W. Browne, H. Brown, Porter, Fagan, Ball and Hill.

The minutes of the former Annual Meeting having been read and confirmed, Dr. Hill (Secretary) read the report of the Council which on the motion of Dr. Hill, seconded by Dr. Fagan, was adopted.

The report of the Library Committee was then read and adopted.

Dr. MacCormac then read the Treasurer's report.

Moved by Dr. Murney and seconded by Dr. J. W. T. Smith that the very satisfactory report now shall be adopted.

The election of office bearers then took place with the following result viz

President

Dr. J. W. T. Smith

Vice-Presidents

Drs. John Moore, Murney

Council

Drs. Stewart, H. Brown, Fagan, McCrea,
H. S. Purdon, Whitaker

Treasurer

Dr. William MacCormac

Secretaries

Drs. Hill and A. M. Porter

The new President having been installed it was moved by Dr. Stewart and seconded by Dr. Murney that the best thanks of the Society are due to Dr. Cuming our late President—unanimously adopted.

Moved by Dr. Stewart and seconded by Dr. William MacCormac That it be an instruction to the Council to report for the future, at the Annual Meeting, the attendance of its members during the Year, and that such be read at each Annual Meeting before proceeding to the elections of Council. Carried unanimously.

J. W. T. Smith, President

3rd May 1870

Ulster Medical Society
Session 1869–1870
President James William Thomas Smith

ULSTER MEDICAL SOCIETY

SESSION 1869–70

Ulster Medical Society, June 1st 1869

Present, Dr. J. W. T. Smith (President) in the chair, Drs. Cuming, William MacCormac, Fagan, Ball, Hill and Porter.

Dr. Smith read notes of a case of cerebral meningitis.

Paper:¹ Simon Corcorin, a policeman, aged 32, was brought to hospital in a state of unconsciousness on the evening of the 10th of May. All that could be learned about him was that he had been ailing for a day or two, but not off duty, and that shortly before admission he had vomited, and then became insensible. I saw him about two hours after. He was very restless and incessantly turning from side to side, his head felt hot, his face was flushed, his eyes were closed, and he resisted any attempt to open them, the pupils were neither contracted or dilated, skin cool, pulse, 80. Had vomited once since admission to hospital. He slept none during the night, but was somewhat more conscious the next day, as he put out his tongue when asked. When raised up in bed he appeared to suffer pain in the back of his neck. Pulse 68; regular. He was still very restless, and some leeches were applied to his head with difficulty.

During the two following days he gradually recovered consciousness, and on the 13th was able to give some account of his illness. He had been on duty on Saturday 8th, and exposed for six hours to a cold east wind. On the following day he felt chilly, and had pains in his head and back. On Monday he attended the Police Court as a witness, and when there became sick, and remembered nothing after till he found himself in hospital.

May 14th.—There is a loud mucous r le in the trachea, and large bronchi, and the breathing is occasionally stridulous; the chest is resonant on percussion, and some sonorous r les are heard in both lungs. He does not appear to suffer from dyspnea. Pulse, 72; respirations, 28.

On the 16th the chest was quite free from mucus; he complained but little of his head, and answered questions sensibly. During the next four days he slept little, was delirious at night, and had almost constant hic-cough. The pulse remained steadily at 60.

On the 21st, having slept well all night from an opiate, he became suddenly affected as on the 14th, the mucus was in such quantity that asphyxia seemed imminent; the face was livid, and the pulse rose to 120. Towards evening this passed away; he was free from

pain, but said that his head felt numb, and as if at some distance from his body. He remained for the four following days in a state of great prostration; he often talked incoherently, but when spoken to answered sensibly. He always insisted on getting out of bed to pass water, and drank milk freely.

26th.—Had passed a fair night, breathing perfectly quiet. About mid-day the paroxysm of dyspnea recurred with great violence; in fifteen minutes the features were quite livid, there was a general convulsion, followed by rigidity, and in a few minutes he was dead.

Post mortem.—The head alone was examined. The mass of the brain was healthy and firm, but when sliced, the surface of the white matter showed many red points. The lateral ventricles contained about two ounces of turbid serum. The central substance was healthy, except the corpus striatum, which seemed a little softened at the base; the arachnoid in front of the pons and upper part of the medulla oblongata was opaque, and the sub-arachnoid tissue here, was infiltrated with pus, and recent coagulated lymph. The membranes over hemispheres and other parts of the brain were healthy.

Although the post mortem appearances were such as are commonly found in cerebral meningitis, there was an absence of the more characteristic symptoms of that disease. The headache was never severe, and was only complained of when the patient was questioned. There were no muscular twitchings, rigidity, paralysis or convulsion, except what occurred immediately before death. The attacks of dyspnea were a peculiar feature in the case. The first occurred early in the disease, and indicated, I considered, that the lesion was in close proximity to the eighth nerve near its origin. The attacks recurred with increased severity, and the third was the immediate cause of death.

J. W. T. Smith, President

Ulster Medical Society, July 1st

Present, Dr. J. W. T. Smith (President) in the chair, Drs. Cuming, Murney, H. Brown, Porter, Hill and D. Johnston.

Dr. Murney read notes of a case of extravasation of urine.

Dr. David Johnston exhibited an acephalous f etus.

J. W. T. Smith, President

Ulster Medical Society, 3rd August

Present, Dr. J. W. T. Smith President in the chair, Drs. Murney, William MacCormac, Whitaker, Stewart, J. W. Browne, H. Brown, H. S. Purdon, Mr. Cantrell, Drs. Hill, McWilliam and Porter.

Dr. H. S. Purdon read a paper on discolouration of the skin.

Dr. Murney exhibited recent parts in a case of amputation for railway injury of leg.

¹ [Dublin Quarterly Journal of Medical Science, 1869, v48, p668.]

Moved by Dr. Murney and seconded by Dr. Whitaker "That it be an instruction to the Council to consider their minute of 28th June with reference to Mr. Monck's alleged misconduct and to report at the next meeting."

J. W. T. Smith

Ulster Medical Society, September 7th 1869

Present, Drs. J. W. T. Smith (President) in the chair, S. Browne, Stewart, Cuming, Whitaker, H. P. Rea, McWilliam, W. MacCormac, Fagan, James Moore, Wales, Porter and Surgeon Bartley (of the 54th Regiment).

Minutes of last meeting read and confirmed. Report of Council read and commented on.

Report of Council.

"Moved by Dr. Stewart and seconded by Dr. W. MacCormac that the Council, whilst strongly reprobating the conduct of Mr. Monck, is glad to find, that for some time he had ceased to be a member in accordance with Rule XIX, and that therefore, the Society would appear to be precluded from further action."

Proposed by Dr. Whitaker and seconded by Mr. MacCormac "That the Report of Council be adopted." Passed.

Professor Cuming exhibited a rare specimen of cardiac disease.

Mr. William MacCormac exhibited or introduced a patient in whom he had performed, most successfully, excision of half the tongue, the operation having been accomplished by means of the *Écraseur*.

Paper:¹ COMPLETE extirpation of the tongue is an operation of comparatively recent date, and although in the present instance only one-half the organ was removed, the difficulty of the operation is thereby increased rather than diminished. I have brought the particulars of this case under the notice of the members of this Society, because the operation is comparatively rare, the present being the first instance in which it has been performed in this hospital, and because I am able to demonstrate in the person of the patient himself, whom I present to you for inspection, how successful is the result, what complete comfort he has gained, and how trifling is the interference either with the power of articulation or deglutition.

Before operation this man suffered great pain, could only swallow with much difficulty, and, in short, was partially starved. Now he will tell you he eats, drinks, sleeps with complete comfort, and even though this relief be only temporary, it is for the time being complete.

The mode of operation I adopted was the submental. By means of a median incision between the chin and the hyoid bone and the separation of the *genio-hyoid*, *mylohyoid*, and *genio-hyoglossus* muscles from each other, I was able to pass my finger to the base of the

tongue, the thickness of the tongue proper, or somewhat less than three-quarters of an inch intervening between my finger and the epiglottis. Through this opening, by means of a strong Liston's needle, I carried first a piece of whipcord, and then, by means of it, the chain of Chassaignac's *écraseur* to the position where I desired to effect the division.

I will now give a brief history of the case:—

John Corry, sixty years of age, was admitted to hospital on account of painful ulceration of the tongue. He smokes to excess. About six months ago his tongue became sore and ulcerated, and until the present time the ulcer became gradually larger and more painful. On examination I found a ragged oval ulcer the size of a florin occupying the posterior third of the right margin of the tongue, and stretching back to the pillars of the fauces. Around its base was an indurated mass, extending nearly to the median line. There was slight enlargement and tenderness of the sub-maxillary glands on the affected side. The sore itself presented a most unhealthy appearance, and was exquisitely painful. Both deglutition and the power of speech were materially impeded.

The patient urgently asked for relief at any cost of suffering, and accordingly, on August 10th, 1869, I proceeded to remove one half of the tongue. The patient was chloroformed, and an incision made two inches in length in the median line just above the hyoid bone. With very little trouble the submental muscles of the tongue were separated from each other, and the finger reached the base of the organ. A curved Liston's needle, carrying a piece of whipcord, was passed through the centre of the tongue, emerging just above the root of the epiglottis. The needle being withdrawn, was armed with another cord, and through the same opening made to emerge at the side of the base of the tongue. It was now withdrawn, leaving a loop of cord, through which the free end of the first cord was passed, and drawn out through the wound. A loop of cord thus encircled the right half of the base of the tongue, and served to carry the chain of the *écraseur* into the required position. Another cord was adjusted after a similar fashion, passing up through the submental wound, and passing down to it again at the *frænum* so as to embrace the tongue longitudinally. By means of this a piece of strong catgut was adjusted and attached to another *écraseur* similar to Malgaigne's, of the ordinary kind recommended for such operations. This catgut had been tested beforehand, and was considered trustworthy, although it gave way during the operation, and led to some embarrassment. This was overcome by making the transverse section first, and then adjusting the chain of the *écraseur* so as to make the longitudinal section in place of dividing the tongue in both directions simultaneously. It only now remained to divide the lateral attachments of the tongue to the floor of the mouth, and the complete separation of one half the

¹ [Dublin Quarterly Journal of Medical Science, 1869, v48, p707.]

tongue was effected, the section being made on all sides clear of the disease. The division was effected at the rate of one click of the *écraseur* handle per quarter minute. No bleeding whatever occurred from the divided surfaces, and although unnecessary delay was caused by the operation being performed in three stages and with one *écraseur*, it was completed in two hours. After the preliminary steps were completed, the administration of chloroform was abandoned.

Had I to perform this operation again I would certainly use, in preference to all else, Chassaignac's *écraseur* and articulated chain. It has a sawing alternate sort of motion which divides the tissues better, with less risk of hemorrhage, than either the wire rope, or cord, or catgut, which, in point of fact, is not strong enough. Had the entire tongue required removal, two applications of the *écraseur*, one vertical, the other horizontal, would have completed the extirpation in less time, and with greater ease. I would also divide the gustatory nerve as a preliminary step, in accordance with Mr. Hilton's recommendation.

The subsequent progress of the patient was everything that could be wished. The same evening when I visited him he was not depressed, nor was there any bleeding. There was a copious secretion of glairy saliva. On the 14th, four days after operation, the report mentions that the patient was "quite easy, no shock or fever, pulse 88. Wound in the neck perfectly healed, except at one point, where there exuded a few drops of pus. He takes arrowroot, and drinks milk, rinsing out the mouth with carbolic acid gargle. He was able to sit up." Next day the wound beneath the chin was found to be completely healed. The state of the tongue and mouth perfectly satisfactory, and he felt so well as to be able to go out of doors. In short, he was reported perfectly convalescent. In a few days more the wounded surface of the tongue healed also, and he felt an amount of ease and comfort, together with absolute freedom from pain, to which he had been long a stranger. I have only kept him in the hospital, somewhat against his will, in order that he might be able to show himself to you to-night, when you will be able to judge of his condition.

The patient here presented himself for the inspection of the members. He expressed the warmest gratitude for the change in his condition, which was now everything that he could desire. He could speak in such a way as not to attract remark, and looked extremely well. On examining the mouth it was difficult to imagine so large a portion of the tongue had been removed, and no trace of diseased action anywhere remained. The portion of tongue removed, exactly one-half of the organ, was also exhibited.

Nothing could well be more satisfactory than the result achieved, and although the disease will almost inevitably return, the poor man will enjoy a period of complete immunity from suffering. His former condition may be realized when I tell you he begged that

some operation should be attempted, even though he should die during the course of it, or immediately after, his sufferings were so unendurable. When we contrast this mode of operation with that of Mr. Syme, who divided the lower lip, chin, and lower jaw, holding its halves asunder while the base of the tongue was swept across with the knife, or the diseased parts dissected out, we cannot wonder at that surgeon strongly objecting to the propriety of attempting this operation, although he himself was one of the first to perform it.

Regnoli successfully extirpated large portions of the tongue by pulling it down through a large wound made along the inner border of the lower maxilla from one angle to the other; and Mr. Gamgee and other surgeons have likewise adopted this method. These are, however, most severe procedures compared with that introduced by Chassaignac in 1850, to whom the invention undoubtedly belongs. The *écraseur* divides the tongue with great ease, and it is necessary not to permit the instrument to do its work too quickly. The long periods, extending to forty-eight hours, which were consumed in Chassaignac's first operations, are by experience found needless, but I would exercise much caution in going to the opposite extreme, when all the advantages of the method will be lost.

Mr. Nunneley, as he mentions in his address delivered to the British Medical Association at Leeds, has since practised M. Chassaignac's operation with great success, having performed it some nineteen times. Mr. Jessop, in a letter to the British Medical Journal of September 4th, 1869, establishes Chassaignac's claim to priority, which Mr. Nunneley had seemed to assume for himself. Before Chassaignac, Jules Cloquet had described this operation, using the ligature in place of the then unknown *écraseur*.

Mr. William MacCormac narrated three cases of strangulated hernia upon which he operated, giving interesting details of each.

The thanks of the meeting were accorded to him and Professor Cuming for their instructive and interesting contributions.

Dr. Samuel Browne read a letter from Dr. Martin of Portlaoise (President of the Irish Medical Association) in reference to the introduction of scientific matter into the Association so as to have a similar basis to that of the British Medical Association at the same time remaining distinct from the latter corporation.

Dr. S. Browne, whilst advocating the object of the letter, desired to ascertain the feeling of his professional brethren in Belfast for the subject.

Professor Cuming thought the change should succeed but he considered that it would be putting the members at a disadvantage not to give them time for consideration on the subject. Still he questioned if medical science could easily be shoved into a society of the character of the Irish Medical Association.

Dr. McWilliam thought an Irish branch of the British Medical Association would be better.

Mr. MacCormac agreed with Dr. McWilliam.

Several remarks followed from other members whereupon the President stated that the proposition did not appear to be favourably considered.

Dr. S. Browne then said that he would write and state the foregoing remarks to his correspondent (Dr. Martin).

J. W. T. Smith

23rd November 1869

Present, Dr. J. W. T. Smith President in the chair, Drs. Stewart, Cuming, Murney, MacCormac, John Moore, McWilliam, Fagan and Hill.

Dr. William MacCormac showed a tumour of the tibia which he had removed by amputation through the knee joint and gave the history of the case.

It was diagnosed by Dr. MacCormac and his colleagues as a benign growth, but the microscope showed that it had characters of a malignant type. It will be interesting to watch the further history of the case.

Dr. MacCormac also referred to a somewhat similar case where he had removed the leg for a malignant growth and the history of which he detailed to the Society on the 21st December last.¹ He stated that the case had turned out as he expected unfortunately, the patient having died recently with every appearance of secondary malignant growths on different parts of his body.

Dr. William MacCormac then showed some calculi which he had removed by lithotomy. He also showed the patients. Dr. William MacCormac then detailed the history of a case in which he had excised the head of the humerus.

Dr. William MacCormac then gave the history of a case of injury of the elbow joint in which he excised a part of the humerus containing the fractured parts of the bone along with the head of the ulna and radius. About 4 inches of the humerus was removed. The parts of bone removed were shown.

J. W. T. Smith

Ulster Medical Society, 21st December 1869

Present, Dr. J. W. T. Smith President in the chair, Drs. Cuming, William MacCormac, McWilliam, John Moore, Wales, Fagan, McMeekin, Porter and Hill.

Dr. John Moore read a paper on craniotomy and detailed the history of six patients in whom the operation had been performed altogether twelve times at different periods.

Dr. Cuming then showed a preparation of abdominal aneurism.

J. W. T. Smith

Ulster Medical Society, January 4th 1870

Present, Dr. Smith (President) in the chair, Drs. Hill, John Moore, McWilliam, Fagan, J. W. Browne, and Porter.

The President read notes on a case of "Erysipelatous after labour". The erysipelatous patch occurred near the anus where piles were situated. In 4 days the eruption crept over the right loin. In a week it had extended over both buttocks. The primary treatment consisted of Quinine, Milk, Eggs, Wine, and Tincture of Muriate of Iron together with the local application of Caustic. No medicine at first seemed to have any effect. Dr. H. S. Ferguson recommended the use of Bisulphite of Soda which had to be discontinued owing to the diarrhoea produced by it. Stimulants, nourishment and opiates then constituted the treatment. The patient was out of danger at the end of a month but not thoroughly well for several weeks after. It was subsequently discovered on enquiry that the nurse in this case had recently been attending a lady suffering from erysipelatous.

Dr. McWilliam next read notes of "A Case of Scarlatina during the progress of which labour occurred". The patient received contagion whilst attending upon her child. She nourished her infant for ten or twelve days after its birth. This infant was in utero for two days during the scarlatinal poisoning of the mother. It was born free from the disease and remained so. The patient is now ill in typhus.

Dr. John Moore then read notes of "A Case of Paraplegia" and gave P.M. results. The only treatment from which benefit was derived was the subcutaneous injection of morphia. There was swelling of the limbs, which Dr. Thompson of Lisburn diagnosed as consequent on a pelvic tumour. The P.M. proved his diagnosis correct.

John Moore

Ulster Medical Society, January 18th 1870

Present, the President (Dr. Smith) in the chair, Drs. John Moore, James Moore, Stewart, Whitaker, Thomas Reade, J. W. Browne and Porter.

The President exhibited a heart with extensive disease and gave a history of the case. The woman in whom the disease occurred exhibited many peculiar signs and symptoms. The diagnosis was clear as to mitral regurgitation. The signs over aorta were not healthy. The pneumonia which was present shortly disappeared.

The P.M. revealed disease of the aortic, mitral and tricuspid orifices. The condition of the aortic orifice was worse than might have been expected from the signs during life. The rarity of systolic murmur was corroborated by this case. There was no dropsy present. The pneumonia must have been acute as it resolved itself in hospital. There was an absence of the peculiar pulse of aortic regurgitation. There was minimal thickness of the mitral valve.

¹ [See page 1126.]

Ulster Medical Society
Session 1869–1870
President James William Thomas Smith

The case was afterwards commented upon by Dr. Thomas Reade and other members.

Dr. Angus Porter next read a portion of a paper on “Syphilis”, which was followed by comments from Drs. James Moore and Reade.

John Moore

Ulster Medical Society, February 1st 1870

Present, Dr. John Moore (Vice-President) in the chair, also Drs. Thomas Reade, H. P. Rea, McCrea, H. Brown, Porter, McWilliam and H. M. Johnston.

Dr. John Moore read a paper on the “Recent Epidemic of Scarlatina” and went into statistics of the cases, from which it appeared that in 66 families, 132 instances of the disease occurred. As regarded the sequelæ 6 cases were followed by suppurating glands and three times that number by dropsy.

A discussion then took place on the question of Weekly Returns of the Causes of Death etc., from the dispensary Medical Officers, Dr. John Moore urging the necessity of increased facilities in this respect.

The general remarks made by the members present appeared to be opposed to Dr. Moore’s views.

J. W. T. Smith

Ulster Medical Society, 1st March 1870

Present, Dr. Smith (President) in the chair, Drs. John Moore, William MacCormac, James Moore, McWilliam, H. Brown, H. S. Purdon, Mr. Cantrell, Drs. Porter and Hill, and as visitors Drs. Dougherty, Armstrong and Mackenzie.

The peculiar case of monstrosity at present being exhibited in town was introduced by Dr. H. Brown who gave an interesting account of the case.

Mr. William MacCormac then gave an account of a case of acute periostitis of the tibia in which it had been found necessary to amputate. The amputation was performed through the knee joint.

At the time he appeared to be in a desperate condition and Mr. MacCormac believed that the reason the boy had escaped pyæmia was that the operation was performed through the knee joint instead of through bony tissue. The specimen was exhibited.

Dr. William MacCormac then showed a patient from whom he had removed a bony tumour of the jaw. The operation was performed only a fortnight ago and yet union has taken place sufficiently strong to allow the boy to masticate.

Dr. James Moore then gave particulars of a case of fungus hæmatodes and at the same time alluded to several operations for the removal of tumours from the same patient. These were brought before the Society last year.¹

Dr. MacCormac then read a paper on cases of syphilis after which it was resolved to hold a Special

Meeting on the 8th March to discuss the Contagious Diseases Act.

J. W. T. Smith

Ulster Medical Society, 8th March 1870

Present, Dr. Smith President in the chair, Drs. John Moore, William MacCormac, McWilliam, Wales, Cumming, Fagan, McGee J.P., Ross, H. Brown, Murney J.P., Walton Browne, Mr. Cantrell, Dr. Hill and as visitors Drs. Dougherty, Armstrong, Bacot and Croker.

The President having stated that this was a Special Meeting called for the purpose of discussing the Contagious Diseases Acts, introduced the subject by laying before the Society a résumé of the various agreements brought forward for and against the acts.

After a long discussion it was proposed by Dr. McGee J.P. “That in the opinion of this Meeting it is expedient to take action for the extension of the Contagious Diseases Acts to the civil population”. Seconded by Dr. Murney and carried with only two dissentient votes. It was further resolved

That the operation of the Contagious Diseases Acts of 1866 in the naval and military towns to which it had been applied has been attended with much success on checking the amounts and severity of the diseases against which it was enacted.

That it has tended to increase morality and to diminish open vice without legalising the latter.

That owing to its operation being confined to only a few towns, and to the imperfect manner in which the provisions of the acts have hitherto been carried out its effectual working is greatly impeded.

That deploring the prevalence of these diseases in this town and in the population of this country,

We believe that such laws should be enacted as shall extend the principles of the said acts to the civil population of the United Kingdom.

It was also resolved that every member of the Society should have an opportunity of signing the document before taking any steps towards publishing the resolution.

It was also resolved that these resolutions be embodied in a Petition to Parliament.

J. W. T. Smith, President

Ulster Medical Society, April 12th 1870

Present, Dr. Cumming in the chair, Drs. Murney, W. MacCormac, James Moore, H. Brown, Anderson, Porter (Secretary).

Dr. Murney gave a very accurate and interesting account of a case of malignant disease of the thigh, necessitating amputation. The operation was performed almost at the joint; the head of the femur and both trochanters being left. The tumour for which the operation was performed occupied the middle third of the thigh and previous to operation became adherent to the bone. Dr. Murney stated that it had formed

¹ [See page 1126.]

within five weeks and that in the month of February it had attained the size of a cocoa nut. Today the patient is reported as doing well and having spent a good night.

In reply to Dr. Moore, Dr. Murney said that the superficial appearance of the tumour, at first, was that of an encysted tumour.

Dr. Moore thought that an exploratory operation might have been adopted to determine beforehand the true character of the tumour.

Dr. Murney remarked on Dr. Moore's observation that the nature of the growth removed on the 1st February had helped to determine him in the course pursued.

Dr. Murney then exhibited a morbid specimen of knee joint disease, implicating the head of the tibia especially at its inner side. Amputation was performed immediately above the condyles of the femur as extensive disease was found in the bones of the joint. One of Teale's operations was adopted. Up to the present the lad had done well. Carbolic dressings were used.

Dr. W. MacCormac next exhibited a diseased tibia (with extensive loss of periosteum and bony substance) which he had removed by amputation of the leg through the knee joint, from a young female child. Previous to operation a diseased condition of the joint was ascertained.

The patient's health having begun to suffer Dr. MacCormac decided on taking off the limb which he did this morning at the site mentioned. The condyloid end of the femur was discovered to be perfectly sound. The stump was well washed with carbolic dressing. Dr. MacCormac concluded by remarking on the advisability of forming the posterior flap first.

J. W. T. Smith

Ulster Medical Society, 26th April 1870

Present, Dr. Smith President in the chair, Drs. Cum-
ing, John Moore, William MacCormac, McWilliam,
Harkin, J. W. Browne, Fagan, H. Brown, Porter and Hill.

Minutes of last meeting read and confirmed.

Dr. Murney exhibited a specimen of brain diseased by alcohol.

Dr. Harkin related a case of scarlatina in a dog.

Dr. Fagan exhibited a specimen of hydatids expelled from the womb in which brandy and ergot were employed.

J. W. T. Smith

Annual Meeting Ulster Medical Society, 3rd May 1870

Present, Dr. J. W. T. Smith President in the chair, Drs. John Moore, Stewart, McWilliam, Gribbin, W. MacCormac, Fagan, J. W. Browne, H. P. Rea, H. Brown, and Porter.

Dr. Porter read the report of the Council.

Dr. W. MacCormac then read the report of the Treasurer.

Moved by Dr. John Moore and seconded by Dr. Gribbin that the report of the Council be adopted.

Moved by Dr. Stewart and seconded by Dr. Hill that the report of the Treasurer now read be adopted.

The members then proceeded to elect office bearers with the following result

President

W. MacCormac M.A., M.D., L.R.C.S.L., M.R.S.A.

Vice-Presidents

Drs. Stewart and Murney

Council

Drs. Porter, Hill, McWilliam, Fagan, Browne, Rea

Treasurer

Dr. J. M. Pirrie

Secretary

J. Walton Browne B.A., M.D.

Dr. Smith having left the chair it was taken by Dr. William MacCormac.

Proposed by Dr. Stewart, seconded by Dr. Gribbin and carried unanimously that the best thanks of the Society be given to Dr. Smith for the valuable services rendered by him to the Society during the past year.

Proposed by Dr. Smith and seconded by Dr. John Moore that the thanks of the Society be given to the retiring Secretaries, Drs. Hill and Porter.

It was moved by Dr. Hill and seconded by Dr. Smith that in future there be only one Secretary to the Society.

Proposed by Dr. John Moore that the privileges of Life Membership be not accorded to future members.

Moved as an amendment that the privileges be extended only to members of 30 years duration.

It was then moved by Dr. Stewart that the subject relating to the privileges of Life Members be considered at the next Annual Meeting.

Moved by Dr. Stewart and seconded by Dr. Hill and passed that "Journals" do lie upon the table of the library for a period of one week, in order that they may be consulted by the members of the Society before being circulated.

Moved by Dr. John Moore and seconded by Dr. Gribbin that the day of meeting be changed from Tuesday at 7.30p.m. to Saturday at 3.30p.m.

Dr. J. Walton Browne and Dr. Hill were appointed to examine the Museum during the summer.

Dr. H. Brown and Dr. Fagan were appointed a Library Committee and requested to examine and report upon the condition of the library.

Robert Stewart, Chairman
13th May 1870

Ulster Medical Society
Session 1870–1871
President William MacCormac

ULSTER MEDICAL SOCIETY

SESSION 1870–71

Special Meeting, Belfast General Hospital, 15th May 1870

The President (Dr. MacCormac) in the chair, present, Drs. Stewart, Dr. Whitaker, Dr. Brice Smyth, Dr. H. S. Purdon, Dr. J. E. Beck, Mr. Grattan, Mr. Pring and Dr. J. Walton Browne.

“For the purpose of considering the laws about to be made as regards the compounding of medicines in this country.”

Mr. Grattan said that by the laws of the Pharmaceutical Society of England, all persons prior to the year 1867 who had been occupied as druggists, would be allowed by passing a very modified examination to practice as a properly qualified Apothecary and be put upon a level with the Licentiates of the Apothecaries Hall, Dublin.

Dr. Whitaker had no objection to members of the Pharmaceutical Society of England coming over to Ireland and practicing as Apothecaries, but he had a decided objection to men, who had formerly been mere druggists, passing a modified examination, coming over to practice in Ireland as Apothecaries and at once putting themselves upon the level with the Licentiates of the Apothecaries Hall (Dublin).

Dr. Whitaker urged upon the Society to take steps to represent to Government to see that the standing of the Candidates for the membership of the Pharmaceutical Society should not be lowered.

Dr. Whitaker proposed and Dr. Stewart seconded that a Sub-Committee consisting of Drs. MacCormac, Walton Browne and Messrs. Grattan and Pring be formed to draw up a memorial to Parliament.

Petition written and forwarded to Thomas McClune Esq. M.P., 17 May 1870

To the Right Honourable and Honourable the Members of the House Of Commons in Parliament assembled

Petition of the Ulster Medical Society humbly
sheweth

That for the last seventy-nine years the practice of Pharmacy in Ireland has been exclusively carried on by the Licentiates of the Apothecaries Hall Dublin, to whom the special privileges were accorded by Act of Parliament.

That during that time Pharmacy in Ireland was and still continued to be conducted in such a manner as to give satisfaction and confidence both to the Medical profession and to the public.

That it has been brought under the notice of your petitioners that a Bill to amend the laws relating to Pharmacy in this country has been laid before your honourable house.

That your petitioners would earnestly deprecate any change which would tend to lower the standard of special pharmaceutical knowledge at present required to be possessed by Licentiates of the Apothecaries Hall, Dublin.

That your petitioners consider that any person (not at present qualified to do so) wishing to open shop in Ireland for the practice of Pharmacy or compounding of medicines, previously to his being admitted to do so, should follow a prescribed course of study in matters relating thereto, and give prove by examination of his fitness for the discharge of pharmaceutical duties.

Your petitioners therefore humbly request your honourable house to take into consideration this memorial.

Signed upon behalf of the members of the Ulster Medical Society.

W. MacCormac P.R.C.S.I., President
J. Walton Browne B.A. M.D., Secretary

Ulster Medical Society Special Meeting, 23rd May 1870

Dr. MacCormac (President) in the chair. Present, the Mayor (Dr. Samuel Browne R.N.), Drs. Murney, H. P. Rea, Stewart, Thomas Reade, H. Brown, Hill, McWilliam, Cuming, Whitaker and Dr. J. Walton Browne. Also Mr. Grattan.

To consider 1. The new Medical Act Amendment Bill. 2. The question of the representation of the Medical Profession in the Medical Council. 3. The new Irish Pharmacy Bill.

The President pointed out the purpose of the Medical Act Amendment Bill, and read over several clauses.

Moved by Dr. Cuming and seconded by Mr. Grattan that for the satisfactory working of the new act it is necessary that the Apothecaries Hall of Ireland should cease to be one of the Medical Authorities, and no longer send a representative to the Medical Council. That the Apothecaries Hall should be [devoted] to the science and practice of Pharmacy, and that their function as a body competent to license practitioners of Medicine and Surgery should be cancelled by the act.

Second resolution. Proposed by Thomas Reade, seconded by Dr. Stewart and resolved, That we decidedly disapprove of the too absolute powers given to the Privy Council of negating any schemes proposed for adoption to the Privy Council by the Medical Council.

Third resolution. Proposed by Dr. Whitaker and seconded by Dr. Hugh Porter Rea. That the Diploma

of Licentiates granted by the Examining Board be an Imperial Diploma and bear nothing on the face of it to show in what part of the United Kingdom it was granted; and that the second column in schedule three be expunged and also the portion of clause fourteen bearing on the subject.

Moved by Dr. Stewart and seconded by Dr. Hill That the foregoing resolution be embodied and forwarded to Parliament.

W. MacCormac, President
November 5th 1870

First Meeting 5th November 1870

Dr. W. MacCormac in the chair, Drs. J. Moore, W. McGee, Drennan, H. S. Purdon, Ball, Fagan, W. Browne, Harkin, McWilliam, H. P. Rea, Mr. Wood, Dr. T. H. Reade, Dr. Wales, Mr. Grattan, Dr. H. Anderson, Dr. H. MacCormac, Dr. Stewart, Dr. Murray, J. M. Pirrie, Dr. F. E. Beck, Dr. H. M. Johnston.

Minutes of previous meeting having been read the President Dr. W. MacCormac gave the opening address—Surgical experience gained during the present war.¹

Second Meeting 19th November 1870

Present, Dr. Stewart in the chair, Drs. Browne, Reade and John Moore.

Dr. John Moore was to have read a paper upon pyæmia but as the meeting was very small the reading of the paper was postponed until this day fortnight.

Third Meeting of the Society 3rd December 1870

Present, Dr. Stewart, Vice-President, in the chair, Drs. MacCormac, John Moore, Fagan, Brice Smyth, McWilliam, and Murney.

Dr. John Moore read notes of a case of pyæmia occurring in the person of a millworker who had received a laceration of hand requiring removal of a finger which was performed in the Belfast General Hospital where the patient was retained until the wound was nearly cicatrized.

The symptoms of pyæmia set in a fortnight after the dismissal from hospital, the case terminated fatally.

Dr. Murney, J.P., gave the history of a case of excision of the shoulder joint for necrosis of the humerus.

Dr. Murney exhibited the recent parts of a case of luxation of the femur at the lower margin of the ischiatic foramen.

Dr. Murney also exhibited a patient with an extensive healing surface on the dorsum of the hand on whom he had transplanted skin four times.

John Moore, Chairman

Fourth Meeting December 17th 1870

Drs. John Moore; in the chair, H. MacCormac, John Smyth, H. S. Purdon, MacWilliams, J. Walton Browne, A. M. Porter.

Dr. H. MacCormac read the first portion of his paper entitled “Some remarks on the more recent progress of anatomical science—general and comparative.”

Paper:¹ *Some Remarks on Structure and Function, in Advocacy of the Spiritual Origin and Direction of Life, in Contradistinction to Blind Brute Force and Automatic Will.*

Anatomy, human and comparative, general and special, in its present state of approximate perfection, is the result of the labours of a long series of inquirers. Aristotle, that great genius, made it, among so many other matters, the subject of his careful attention. He did not understand the action of the muscles, although he noticed their development, as it varied in different classes of animals. On Erasistratos of Ceos devolved the credit of determining that, in order to act, a muscle must needs contract;² also the discredit if, indeed, it be true, of dissecting men alive. Galen pointed out that blood filled the vessels and the heart, showed how lesions of the nerves and medulla implicate muscular action, and even induce paralysis. Passing over some fourteen centuries of barbarism and contention, we come to Berengarius, of Bologna, a city which he was constrained to leave, charged with having examined the bodies of a couple of Spaniards ere the vital spark had fled. This able anatomist, by his multiplied inquiries, paved the way for his successor Vesalius who, singular to relate, incurred a like evil repute in respect of a Spanish nobleman by him erroneously imagined to be dead, and only escaped through the intercession of Philip II., on condition of a journey to Jerusalem, perishing on his way back.

Servetus first appears to have made known the cardio-pulmonic circulation, and likewise the depuratory action of the lungs. Eminent as a philosopher, happening to differ on a speculative point from a no less eminent divine, he was by him and others, infamous and almost incredible to relate, entrapped and burnt alive, a frightful example of the irony of fortune, in that he who lavished the divine gifts of genius on his species should experience destruction as the requital in return. Malpighi distinguished himself in numerous particulars, among the rest by the employment of the microscope in anatomy.

Harvey's demonstration of the greater circulation, at or about the year 1618 or 1619, was simply and truly the result of the admirable application of anatomical knowledge. He was not, indeed, the first to detect the valvular structure of the veins, but he was clearly the first to deduce from that structure the immensely

¹ [Not found but see his book *Notes and Recollections of an Ambulance Surgeon*, London, J. & A. Churchill, 1871, for his experience.]

¹ [Dublin Quarterly Journal of Medical Science, 1871, v51, p371.]

² Marey, *Du Mouvement dans les Fonctions de la vie*, p. 9-11.

important inference that registers his name in the records of our kind.

Valsalva, and his pupil Morgagni, both made amplest contributions to anatomical science in their time. The discovery of the pancreatic duct has been ascribed to Wirsung, as well as to Eustachius, who made known to us in detail the tubes which bear his name. Pecquet detected the chyliiferous ducts, while Rudbeck and Bartholinus determined the constitution of the lymphatics. Ruysch was indebted to Swammerdam for a knowledge of the material which he employed in making his admirable injections. Having disposed of his first museum to the Russians, Ruysch, who had been meanwhile disabled by a fall, employed himself in the formation of a new one, a task in which, it may prove of some interest in these days of lady doctors to remember, he was most ably assisted by his youngest daughter. Not those great men only whom I have named, but many others, as Albinus, Winslow, Vicq d'Azyr, Stahl, Hoffmann, and others, by their zealous toil and persevering industry, very greatly added to the sum of our attainments. Of Haller, indeed, it is difficult to speak in terms of moderate eulogy, so great were his achievements in almost every branch of anatomy and physiology.

Few observers, however, whether English or foreign, surpassed the Hunter brothers in respect of the interest and importance of their inquiries. Their collections, the Hunterian Museum of London in especial, are replete with evidence of their vast research, and can never, I think, entirely lose their value, however far reaching may prove the results of future inquiry. The world has endorsed the well earned repute of these our medical fathers, some of whom, though now securely illustrious, paid dearly enough for the position to which it has been their great good fortune to attain.

Anatomy is the science of organization, the knowledge of what Haller tersely styles the fluid and solid parts.¹ Organic unity is the great, the momentous fact of living nature. Initiated by the Greeks, its truth seems now admitted by every investigator. There is no origin or beginning in the body, observes wise Hippocrates, the parts, all of them, are equally, both beginning and end, for in a circle there is no beginning.² A like remark might be applied to the living functions which, in fact, are solidary of each other, without beginning as without end. Geoffroy Saint Hilaire attached less moment, however, to the organs, with their variable forms and functions, than he did to their composition, together with, as he named them, the four laws of organic life, to wit, the theory of analogues, the principle of connexion, elective affinities, and the balance of the organs them-

selves.¹ Every organism, indeed, undergoes, or if you will, performs, a series of acts from birth to death, various, however, as the conditions of life and organization themselves vary.²

According to Milne Edwards, speaking of the constituents of the living frame, the form and disposition of the different tissues and dimensions of the organic molecules or globules, are alike in all animals. The diameter of the molecules he lays down as $\frac{1}{300}$ of a millimetre.³ The fundamental material of all the tissues, nerves, bones, muscles, and connective tissue alike. Dr. Lionel Beale, who has isolated it by submitting it to the action of the ammoniacal solution of carmine, terms bioplasm, or living plasm, germinal or growing matter.⁴ It is particularly abundant, he tells us, in the muscular tissue of the heart, where new tissue is incessantly formed to replace that which so rapidly wears away.

Bichat reckoned up fourteen several tissues, leaving out, singular to relate, the cellular tissue, most important and generally diffused of any, since it is, in fact, the common matrix or mould of that by which and in which each and every structure is imbedded, pervaded, and enclosed, the basis of bone, the bulk of the viscera, arteries, veins, nerves, and absorbents.⁵ The occurrence of emphysema after certain wounds, the custom once common of fraudulent butchers in blowing up meat, and of horse chaunters in filling up the hollow above the eye in aged horses before selling them to unwary customers, as well as the practice of a wretch in London who used actually to blow up the subcutaneous cellular tissue in a little boy, whom thus distended, he exhibited as a show, all go to prove the great pervasiveness of the cellular tissues.

Van der Hoeven reduces all the tissues to eight, as the conjunctive, vascular, adipose, nervous, corneous, cartilaginous, muscular, and elastic.⁶ The cellular, vascular, and nervous, Meckel esteems the fundamental tissues.⁷ Rudolphi unites with Haller in dividing animal structures simply into solids and fluids,⁸ assigning, however, as Aristotle did before him, the preponderance to the fluid.⁹ If one, however, would have other than the merest general ideas, one must, perforce, isolate the tissues.¹⁰ No animal, save man, the anaploterium excepted, observes Cuvier, has an uninterrupted series of teeth.¹¹ And man, too, I would say, is also the only

one in which the incisors form a right angle with the plane of each jaw.

The facial angle on which Camper laid so much stress, and which the Greeks so greatly exaggerated in their ideal statuary, according to Meckel, is seventy-five in the Mongolian and eighty degrees in the Caucasian man. Our erect stature, although at a great expenditure of means, may be said to be exclusively our own. And half the head, which is the case with no other creature, a fact, so far as I know, first stated by Winkelmann, in his admirable essays on art, is placed above the plane of the orbit. In other respects man, as Huxley insists,¹ shares certain morphological conditions with other animated organisms, but, when classed, each group displays structural characters common to the members of that group only, and isolating it from all others. Thus, among the vertebrates, mammals possess two occipital condyles, a well ossified basioccipital, each ramus of the mandible composed of one bone articulated with the squamous element of the skull, and non-nucleated red blood corpuscles.

The basis of medical science, observes Pinel,² reposes on facts, it is so also in anatomy, it is so in everything. But, as Aristotle says, we must proceed from the simple to the complex, from the better to the less well known, just as in dealing, for so he puts it, with³ coins, ὄσπερ νόμισματα. Science, in truth, is progressive ever. But while the inquirer busies himself with one portion, the rest is advancing ceaselessly, so as to render it difficult to retain everything within his grasp.

Without impeachment of the claims of any, a more remarkable person than Bichat has never, perhaps, adorned the great cause of anatomical research.

And however well-founded may prove the undoubted merits of our Homes, Hewsons, Pritchards, Carpenters, Goodsirs, Busks, Bowmans, Hassalls, Ralphs, Bennetts, and others, to Bichat is certainly mainly owing the foundation of modern general anatomy. Born in the department of the Ain, he removed at an early period of his career to Paris, where, having been one day called upon without any special preparation or previous notice, to report, *vira voce*, a lecture of Desault, the person charged with that duty having failed to appear, he acquitted himself so admirably that the great surgeon at once received him in his house and treated him as a son. Struck with the masterly manner in which Pinel had treated of the serous and mucous membranes, Bichat himself took up the topic, and, some time after, published his book on the Membranes, followed, in succession, by his *Life and Death*; and lastly, his *General Anatomy*.⁴ A fall down the stairs of the Hôtel Dieu, resulting in fever and death, to the infinite regret of every one, brought

Bichat's indefatigable energies to a close, and, at the comparatively early age of thirty-one, robbed the world of the ablest and most philosophical anatomist for his years that had ever lived. His writings, though somewhat over copious, are replete with keen inference and admirable research. It was Bichat's ambition to found medicine on anatomy, and doubtless, had he lived, he would at least have striven to compass his design. Those who have nothing to say, observes one of his biographers,¹ are prone to tell you that everything has been said. It is quite otherwise, however. Before the man of true genius and observation the fields of discovery extend far and wide. To him, indeed, nature delights to unseal her hidden treasures, treasures that remain hidden to the idle and inapprehensive. As it is, Bichat has left amplest materials for thoughtful investigation, and, as thus, has bequeathed a heritage which, or at least much of which, must, I think, for ever endure.

It seems to be a condition of progressive thought and action that the inquirers of one age shall conduct a series of investigations to a given point, when others shall take them up, and, perchance, achieve results which to the first are simply unthought of and unknown. Such, in effect, have proved the issue of the labours of Dr. Lionel Beale and M. Charles Robin, both ardent cultivators of histological and general anatomy, as contrasted with and supplementing those of Xavier Bichat. Older anatomists were at least excellently well acquainted with the general outline, the bones, muscles, nerves, vessels, and viscera of the living frame. Bichat, however, showed that there were other things to be considered also, and came forward with his famous, but at the same time somewhat artificial, division, into symmetrical organs or those of animal life, and the non-symmetrical or those of organic life, the first comprising the brain, spinal marrow, their nerves, and appendages, the second including the vascular system, great sympathetic, digestive, respiratory, and renal apparatus.²

Dr. Beale's most recent exposition appears in his work, *The Mystery of Life*, setting forth his reasons for dissenting from those who esteem structure and function merely correlations of matter and the ordinary material forces of nature, resultants, in fact, of the non-living world, instead of, as he states in his treatise on protoplasm, a power, force, or property of a special peculiar kind, temporarily influencing matter, and its forces, but different from, and not merely correlative with, them. I most cordially concur with Dr. Beale that Life is not the result of the brute forces of nature, and proceed at once to cite from his truly important remarks on bioplasm. Connected with every tissue, he tells us,³ are certain oval, circular, or irregular masses. These soft structureless masses, differing from matter

³ Mystery of Life, p. 35.

in every other state, he terms bioplasm. By subjecting tissues, immediately after death, to the action of carmine in ammonia, bioplasm is obtained of a deep red colour, while the tissue, nerve and muscle alike, remains colourless. The aspects of bioplasm, thus coloured, Dr. Beale has set forth in his admirable plates. This important constituent of living bodies, being normally colourless, has even been passed over as of no moment, its presence regarded as accidental, and every trace of it omitted in text-books. Five times as many bioplasts exist in the heart, owing to the activity of the changes in its muscular tissue, as in ordinary muscular fibre. Some bioplasts go to form muscle, others nerve. Others again form connective tissue, but nerve bioplasm cannot be distinguished from that which makes up muscle, or either of them from connective tissue bioplasm. At an early period indeed, when the heart, in this instance speaking of the hyla or tree toad, is represented by spherical bioplasts, there is not a vestige of muscular or nervous tissue, but merely the living matter by which alone the formation of such tissue is possible. As development advances, however, the bioplasts recede from each other, and tissue appears. But the bioplasm does not disappear. It continues to take up nourishment, which is converted into bioplasm, and thence, *pari passu*, into tissue. Into Dr. Beale's further remarks on the distinction which he draws between life and mere physical force, I need not here further enter. Not only on these grounds, however, but in respect of his remarks on minute nerve structure, his treatise deserves the most careful study.

The humoral pathology and physiology once so extensively in vogue, was perhaps too summarily dismissed. In strictness, the humours, the blood, are solidary, in fact, part and parcel, in respect of life and function, of the tissues. The solids are made up of various ingredients, principles, in truth, anything but homogeneous, which M. Robin divides into three classes.¹ They constitute the simple principles of biology, not less essential in the interpretation of living facts to the anatomist, than are those of chemistry and natural philosophy to the student of physics.² The determination of muscular action and creation of power through the mere fiat of the will, is one of the most wondrous particulars nay, the most wondrous particular, of animal life. It is a power shared by the whole animal creation, but how it takes place we neither can know nor imagine. It is accomplished, at least speaking of the voluntary muscles, through no brain action, no conscious or unconscious cerebration, seeing that there is nothing of the sort considered as a mental act, but through a direct volition of the intelligence.

Felted and welded together, the anatomical elements make up the basis of the individual. They comprise the

variously formed cells, fibres, and tubes. Cell structure, excessively diffused, includes the red and white blood corpuscles, the elements of bones and nerves, with those of the central nerve substance, ganglions and epidermis. Elementary muscular fibres vary as they belong to those of organic or animal life, to borrow the language of the writer of the very able summary in the *Revue*. The connective and elastic tissues are also constituted of special fibres. There are tubiform elements in the nerves of animal life, white filaments of the great lymphatic, the myolemma which envelops the fascicles of the muscular fibres of animal life, capillaries, glands, parenchymatous structures, and lastly, the tubes which go to make up the nerves. M. Robin discriminates carefully between the tissues and their anatomical elements, invisible to the naked eye, wherein life's fire doth mainly burn. The red blood globules are of an infinite and hitherto quite unsuspected complexity, form indeed the immediate element, as Claude Bernard terms it,¹ of our ever-renewed organic perfectibility. The histological elements which compose the living organism, as formed by the red globules, are not laid down at random.² Like elements combine with like to form tissues which, in their turn go to make up organs of severally varying structure, complexity, and use.³ Assimilation and disassimilation, homoimorphy and heteromorphy, absorption and secretion, substitution and interpolation, proceed on a predetermined plan ceaselessly and without pause together. Old materials are shunted off into the venous current, while, again, new blood discs for instant use are formed within the arterial current itself.⁴

Philosophical anatomy strives as best it may to explain the processes of growth and decay, amid two orders of forces, vital and general, at work ceaselessly, and, whatever may be said, in only too many respects one as little known and understood as the other.⁵ The same thought is somewhat differently expressed by Chevreul, when he observes that living bodies are so much the more complex by reason of adding general physical qualities to the special conditions of their vitality.⁶ And thus it is that the sum of the latter may be divided into consenting and opposing forces of complex and varying energies.⁷ For the principle of vitality, life itself simply designates organic activity considered as a

whole.¹ There is an uninterrupted correlation not only of the interior parts but of the inward and outer organs, in such wise that one proves, as it were, the virtual exponent and unvarying outcome of the other.² The able zoologist or anatomist, some Cuvier of the present, from a given organ or merest fragment, were it, will detect genus and species, even age and sex, as well as the distribution in the order of space and time, with almost unvarying certainty and correctness. The general tendency of histological inquiries, what Leydig would term the comparative doctrine of tissues,³ observes Müller,⁴ has been to refer to cell formation the actual genesis of the tissues themselves. This process, however, must surely ensue in the very centres of nutrition, those minute cellular structures, as Goodsir terms them,⁵ already existent in the texture of organs. The sections of minute structure which Leydig gives, as in regard of the dog, calf, eel, bird, and cæcilia annulata, in particular, are, I think, of great interest, and go far, perhaps, to constitute his important treatise, as was that of Swammerdam longo intervallo before him, a veritable outline of the vast superficies of living nature.

Evolution and nutrition belong to each and every anatomical element, and yet, one is very distinct, indeed, from the other. For anatomical elements, when they first appear, are not what they afterwards become. They gain in volume, assume forms more perfect, which again in turn, pass away. In fine, organic phenomena, in their relations to the anatomical element, may be summed up under four divisions, to wit, nutrition, evolution, contractility, and innervation. In some mere human machine one motor commonly suffices, but in the living organization many factors, numerous forces, endless complications, countless elements, are at work constantly in the effective, ceaseless furtherance of the different processes of life.⁶ Every organized substance, according to M. Robin, determines in its neighbourhood new anatomical elements, forms of activity, by means of segmentation, gemmation, and the fruitful action of the blastema. A minute nucleus, surrounding itself with solid matter, continually elaborates those cells, fibres, and tubes which contribute to, in fact, constitute, the never ceasing manifestations of organic life and being.

¹ Le nom de vie ou de vitalité est réservé pour désigner le mode d'activité propre à l'organisme considéré dans son ensemble comme un tout unique. Robin, Histoire Naturelle de Vegetaux Parasites, p. 56.

⁵ Pathological Observations, Centres of Nutrition.

⁶ Les parties intérieures sont les appareils qui se subdivisent en organes lesquels se groupent en systèmes divisibles en tissus et humeurs susceptibles d'être ramenés à un certain nombre d'éléments anatomiques ou organiques et de principes immédiats. C'est à ce tout formé par la réunion de toutes ces parties, qu'on donne le nom d'organisme.—Robin, Hist. Nat. p. 27.

Blastemas are various as there are tissues, in other words, the anatomical elements of each given tissue permit amid their interstices those generative fluids, from which similar elements spring. Organic corpuscles, which but an instant before had no existence, are produced in ceaseless molecular affluence, how, we know not, unless, as I conceive we are bound to do, we ascribe it to a predetermined will and power which, in the entire living structure as in its several parts, act in virtue of an archetype, devised by a Divine intelligence and unalterable skill.¹ The amœba, for example, takes food into its interior, and, without a single visible digestive organ, in virtue of some inexplicable power, selects what it needs, while it rejects what it can do without.²

The possession of life, indeed, were it in the very humblest organism, some mere rotifer or gregarinid, imparts an interest which as thus it shares in common with the greatest. Van der Hoeven, in his elaborate treatise, the result, he tells us, of the labour of six of the best years of his existence, expresses himself with emphasis on the subject of the almost inconceivable perfection everywhere manifested in the structure of the minutest creature of the organic world.³ Those who under a high magnifying power have watched the varied movements of living matter will not, says Beale, be easily brought to believe that such phenomena are due only to physical and chemical agencies.⁴ In any and every case, however, having done our best, we must, perforce, fall back on the implicit declaration of empirical experiential law, that is to say, on unity of plan with diversity of detail. Happily, says Mr. Huxley,⁵ there is a criterion of morphological truth, a sure test of all homologies, the study of a real and not merely an imaginary development, proves that the doctrine of unity and, as I would add, of a predetermined plan, is not mere fancy, but the expression of absolute law, the utterance of well established facts.

M. Robins' doctrine as to the genesis of anatomical elements in the heart of the blastema itself, is not admitted by every one, for example, not by Virchow, who would refer the origin, or at least, the extension of cells, to proliferation, and of other elements to metamorphosis. But anatomical elements, not to speak of morbid products, are often so dissimilar, muscular fibres and nerve tubes resemble each other so little that

¹ La connaissance d'un être tel que l'homme, a existé avant que l'homme fit son apparition, car l'intelligence divine, en formant l'archétype, avait la prescience de toutes ses modifications.—Owen, Principles of Comparative Osteology. French Ed. p. 12.

² Nicholson, Manual of Zoology, Nature of Life.

³ Die Natur hat in dem Baue des thierischen Körpers eine unbegreifliche Kunstfertigkeit an den Tag gelegt. Nicht nur der Körper in ganzen, ja nicht nur seine grobern Theile, Sondern selbst die kleinsten Theile der Organe sind Werkzeuge und das anatomische Messer zeigt uns bis zur einfachsten Faser nichts als zweckmas-sigeingerichtete Theile.—Handbuch der Zoologie. Band 1, S. 9.

⁴ The Mystery of Life, p. 71.

⁵ On the Study of Zoology.

one hesitates to concede their production to cell origin. There is, in truth, genesis by substitution, that is to say, the wasted elements are redissolved in the circulating medium and dissipated, while others are taken into their place. In fine, the anatomical element is the true arena, the very keystone, so to speak, of material existence, enwraps the secret springs, those hidden energies, whose multiple sum we term life. M. Robin lays claim to the discovery of lymphatics in the brain, the structure of ganglions, the distinction between nerve tubes and cells.

A remarkable feature of his views is that morbid growths, some, if not all, tumours, cancers, cysts, and others, are not so much new growths as a sort of hypergenesis of existant normal tissues. He is very surely in error, however, as to tubercle, since this is not the extension of any living tissue, whatever, but simply, as I assume to prove and show, the deposit of unoxidized retrograde carbon, unoxidized and unexcreted by reason of the habitual respiration of air more or less prerespired. In sum, M. Robin has rehabilitated the humoral pathology, not, indeed, the blind irrelevant pathology of the past, but a pathology purified and adjusted to living realities. The blood, in truth, is the arena of existence, the laboratory wherein transformations ensue, which no chemist hitherto has weighed in his balance, no physiologist detected with his lens. There is no virus either, as apart, the fluids only, M. Robin affirms, become virulent.

In other respects, the fast and fluid parts are solidary of each other, since what is fixed at one instant becomes fluid in the next, and conversely. There is no vital principle, then, as apart from the play of phenomena under providentially regulated control. But a vital principle, as thus, there most surely is. Matter, force, the sun's light and heat, the electric spark, per se, no more originate and discharge the processes of life than they do the confection of our food, the putting on or off of our daily attire. In every thing we witness the, in fact, miraculous harmony and consent of the various processes of the organism. In these controlled, indeed, and regulated by a higher power, may we alone discover the only true solution of the enigma of life. Everything, this premised, may be said to result from the play of the energies of the ultimate particles of the organism,¹ otherwise, as to the principle of the principle, the causation of the cause, the inner mysteries of life and being, we know or can know directly nothing. They are there, but reach them we may not. We can do little other or better than observe, but yet with all our insight, our utmost care. In us and about us there exist nothing but wonders. We proceed a little length, we attain to some faint inklings, but the arcana of existence we are all unable to resolve. And yet to us none the less belong the city of man's existence, the habitat of a

¹ De l'Approximation des Parties Organiques et de l'Organisme à l'Accomplissement d'Actions déterminées, cited in the Revue.

living soul. Ours, in truth, is a right marvellous organism, but, much as we may talk and write about it, of the intimate essence and secret springs of that organism we shall never here, I fear, know more than we do of the state of the dwellers in Arcturus or the condition of the inhabitants of Algarob.

Fifth Meeting 31st December 1870

Present, Dr. Stewart, Vice-President in the chair, Drs. H. MacCormac, Cuming, John Smith and Fagan.

Dr. H. MacCormac read the second portion of his paper entitled "Some remarks on the more recent progress of anatomical science—general and comparative." [See paper above.]

After some remarks from the President, Dr. Cuming stated that he would communicate with the Editor of the Dublin Quarterly Journal with the aim of having Dr. MacCormac's paper published in the next issue of the journal.

The Vice-President wished it to be put upon the notice paper for next meeting that a ballot be taken to fill up the vacancy caused by the departure of H. Brown, L.R.C.S.E from Belfast.

Dr. Stewart also stated that he would propose Dr. Pearsall, L.R.C.S.I. be elected a member of the Society.

W. MacCormac, President
March 25th 1871

25th March 1871

Ordinary Meeting of the Ulster Medical Society

Present, Dr. W. MacCormac (in the chair), H. MacCormac, Stewart, Dill, Hill, McGee J.P., Reade, Fagan, J. W. Browne, John Moore, McWilliam, Cuming.

The President gave a very interesting account of the new St Thomas' Hospital of London.

After the President had given his lecture he resigned the Presidential Chair. Dr. McGee, V.P., then moved that an address from the Medical Society be presented to Dr. W. MacCormac.

Drs. Thomas Reade, Murney, Stewart, Hill, John Moore were appointed a Sub-Committee to draw up and present an address to Dr. MacCormac.

8th April 1871

Dr. Stewart (in the chair), Drs. Browne R.N., J. Walton Browne, James Hill, Fagan, H. S. Purdon.

Dr. Browne R.N. read notes of case of malignant tumour of thigh. The case necessitated amputation which was performed by Dr. Browne upon the 6th April 1871 at the junction of the upper and middle thirds. The tumour was exhibited which proved to be "recurrent fibroid" a microscopical examination of the tumour having been kindly made by Professor Redfern.

Dr. Stewart then brought up for consideration the New Medical Bill.

Drs. Reade, Browne R.N. and Murney were appointed

a deputation to wait upon Thomas McClune M.P. relative to the Medical Bill.

Dr. McGee R.N. was appointed as a Deputation to wait upon Mr. McClune relative to the Lunacy Regulation Bill.

Robert Stewart M.D., Chairman
22nd April 1871

22nd April 1871

Dr. Stewart (in the chair), John Moore, H. S. Purdon, John Fagan, Hill, Pearsall, J. Walton Browne, John Grattan, Murney J.P.

Dr. Murney gave a short résumé of the Medical Bill now before Parliament. Dr. Grattan (of Dublin), a visitor to the Society, offered to bring the Bill before the notice of the College of Physicians.

Proposed by Dr. Stewart that Dr. Murney in conjunction with the Council draw up a Medical Bill and transmit it to the College of Physicians.

Dr. Stewart introduced the Lunacy Bill. Dr. McGee R.N. and Council to deliberate upon the Lunacy Bill.

Dr. Murney introduced two patients upon whom the operation of skin transplantation had been performed.

Annual Meeting 1871

Present, Drs. Stewart (in the chair), McCleery, H. S. Purdon, MacWilliam, Gribbin, Murney, Fagan, McCrea, Wales, Mr. Browne, Proctor.

Dr. Murney proposed and seconded by Dr. Fagan that the length of time for Life Membership be extended from 20 to 30 years.

Dr. Gribbin proposed as amendment and seconded by Dr. McGee that no change as regards the Life Membership be made at present (passed).

Dr. Murney proposed that a sub-committee consisting of Drs. Hill, Walton Browne and Murney be appointed to look after the Museum.

Dr. Murney and Fagan presented their report regarding the condition of the library.

Dr. Murney proposed that a special meeting of the Society be summoned to look over duplicate copies of books and that a list of duplicate copies be prepared, so that they may be sold.

Dr. Walton Browne read the report of Council, moved by Dr. Hill and seconded by Dr. Gribbin that the report of Council be adopted.

Dr. MacWilliam reported that he had obtained £16.16.0 remaining uncollected from last year.

The Meeting then proceeded to the election of office bearers.

Dr. McGee moved and Dr. Gribbin seconded that Dr. Murney be elected President for the ensuing session. Passed unanimously.

Dr. Stewart and Dr. S. Browne were elected Vice Presidents.

Council Dr. MacWilliam, H. S. Purdon, Hill, Wales,

Porter, McClurg.

Dr. Stewart and Dr. Wales [proposed and seconded] that Dr. Fagan be elected Treasurer.

Dr. H. S. Purdon proposed and Dr. Gribbin seconded that Dr. Walton Browne be elected Secretary.

Robert Stewart, Chairman
22nd November 1872.

ULSTER MEDICAL SOCIETY

SESSION 1871–72

Session 1871–72

First Meeting November 4th 1871

Present, the President (Dr. Murney J.P.) in the chair, Dr. McGee P.R.N.A., Dr. Browne R.N. J.P., Dr. John Moore, Dr. Stuart, Dr. Fagan, Dr. MacWilliams.

Dr. Murney (the President) returned thanks to the Society for the honour conferred upon him of having elected him as a President for the ensuing session, and drew the attention of the Society to several matters which may probably come before Parliament during the present year namely sanitary matters, and the "Contagious Diseases Act".

Arrangements were made for the Annual Dinner to be held up on Wednesday the 15th of November 1871 at 6.30 o'clock p.m.

The President, Dr. Browne R.N. and Dr. Patterson were appointed as a Committee to make arrangements for the Annual Dinner.

Dr. H. S. Purdon brought forward his case of general leprosy, and exhibited the patient who suffered from anæsthesia and tubercles; he had been treated at several hospitals in London.

Dr. Murney exhibited a specimen of epithelioma of the forearm which necessitated amputation.

Dr. Murney also exhibited the portion of bone removed in a case of excision of the shoulder joint and exhibited the patient. The patient is now capable of a certain amount of motion at the joint.

Proposed by Dr. McGee and seconded by Dr. Fagan that the Library Committee draw up a list of duplicate books which may be sold.

Henry Murney, Chairman

Second Meeting November 18th 1871

President in the chair, present Dr. H. S. Purdon, Dr. McClurg, J. W. Browne, Hill, Fagan, McGee R.N., John Moore, Dr. Stewart, S. Browne, Gribbin.

Dr. McKeown (M.D. L.U.I.), Dr. B. H. Spedding and Dr. Fergus Brown were proposed as members of the Society to be balloted for at next meeting of the Society.

Dr. Browne R.N. brought forward a case of excision of the elbow joint and exhibited the patient.

The President (Dr. Murney J.P.) then read notes of a case of excision of the knee joint and exhibited the portion of bone removed.

Dr. H. S. Purdon exhibited Piffard's Cutisector and Bayne forceps for epilation

Henry Murney

Third Meeting of Society Saturday 2nd December 1871

President in the chair, present Drs. MacWilliams, H. S. Purdon and Fagan.

The President introduced a patient on whom he had performed the operation of tracheotomy fourteen years ago and who still requires to wear the cannula.

Dr. H. S. Purdon exhibited specimens of [Oly atheril?], a remedy he has introduced into the treatment of certain forms of skin disease and especially successful in the destruction of acari scabies.

The President proposed and Dr. Purdon seconded the rescinding of Rule 11 as presented on the notice paper; passed unanimously.

The Council was requested to review the rules of the Society and report thereon.

Dr. Fagan was requested owing to the smallness of the meeting to hold over the reading of his notes on the present epidemic of small-pox.

Henry Murney, M.D.

Fourth Meeting 16th December 1871

President in the chair, present Drs. Stewart, McGee R.N., John Moore, McWilliam, H. S. Purdon, Murray, Fagan, Hill, J. W. Browne, James Moore, McConnell.

Proposed by the President and seconded by Dr. Fagan that Rule 11 be rescinded; passed unanimously.

Proposed by the President and seconded by Dr. John Moore that the commencement of Society's year be changed from the 1st of May until the 1st of November, and that a subscription of 10/6^d be payable upon 1st May to carry the Society over until the 1st of November 1872.

Both resolutions confirmed.

Ballot was then taken for the following gentlemen: Dr. B. H. Spedding, Dr. Fergus Brown, Dr. W. A. McKeown, Dr. John James Charles, all of whom were declared duly elected.

Dr. Fagan read notes upon the present epidemic of variola. The members after the reading of the paper made a number of interesting remarks upon variola.

Henry Murney, M.D.

Fifth Meeting 6th January 1872

The President (in the chair)—Dr. McGee P.R.N.A., John Moore, Fergus Brown, Charles, Hill, Murray, J. W. Browne, Bennett, Stewart, Spedding, Cuming, McConnell, McCred, McKeown.

Proposed by Dr. McGee that a letter of condolence be drawn up [by] the President, Dr. Hill and the Secretary and transmitted to the friends and relatives of the late Dr. McWilliam.

Dr. Murney (the President) exhibited an extensively lacerated arm, requiring amputation.¹

¹ [See page 1149 for subsequent history.]

Proposed by Dr. Hill and seconded by Dr. B. H. Spedding that James McMeekin be elected a member of the society.

Dr. Murney (the President) exhibited Nélaton's probe and related the particulars of the case in which he had used the probe with success.

Dr. McCred brought forward his proposition that a committee be appointed to consider the position of professional fees in Belfast. Dr. McCred proposed the following committee be appointed to consider the position of the fees: the President, Drs. Cuming, John Moore, Pirrie, Murray, Fagan, McCred, Hill.

Henry Murney M.D., President.

Sixth Meeting 20th January 1872

Present, Dr. Murney President in the chair, Drs. Stewart, Magee J.P., Wales, J. W. T. Smith, McCrea, Moore, John Moore, Charles and Hill.

The minutes of former meeting having been read and confirmed the President stated that the letter of condolence to the friends of the late Dr. McWilliam has been drawn up and was to be forwarded immediately.

Dr. McCrea stated that he had been unable to call a meeting of the committee appointed to consider the state of medical fees in Belfast but that he hoped to do so early in the following week.

Dr. James T. Smith then related the history of a case of pneumonia complicated with pericarditis and effusion into the pleural and pericardial cavities and ending in death. He also brought under the notice of the members Dieulafoy's pneumatic aspirator which he had used in this case to withdraw the fluid from the pleural cavity. The case was chiefly remarkable for the progressive intensity of the inflammation which at first was confined to the lower part of the lower left lobe.

After remarks on the case by several members, and an examination of the aspirator a ballot was taken for Dr. McMeekin Esq L.R.C.P.S. etc. and he was declared duly elected as a member of this Society.

The President having stated that Dr. J. Walton Browne had tendered his resignation of the Secretaryship Dr. James T. Smith proposed and Dr. John Moore seconded a motion to the effect that the best thanks of the Society be given to Dr. Browne and that the members accept his resignation with regret which was passed unanimously.

It was then proposed by Dr. Murray and seconded by Dr. McCrea, that Dr. Hill be requested to accept the office which having been supported by the members present he accordingly did.

Henry Murney M.D., President.

Ulster Medical Society 7th Meeting 3rd February 1872

Present, Dr. Murney (President) in the chair, Drs.

Cuming, Stewart, Gribbin, John Moore, Charles, McMeekin, McConnell, Fergus Brown and Hill.

The minutes of former meeting having been read and confirmed, Dr. Charles proceeded to give an account of a case of avulsion of the right arm and scapula by a mill accident in a boy about 10 years old; the parts mainly required trimming and although there was no hæmorrhage from the axillary artery a ligature was put on it as a safeguard. The boy made an excellent recovery.

Dr. Cuming then related a case of aneurism of the aorta extending from the 9th dorsal vertebra downwards into the right iliac region, distending enormously the opening for the blood vessels in the diaphragm, also sending a small process to the left side. The parts were exhibited.

Henry Murney M.D., President

17th February 1872.

Ulster Medical Society 8th Meeting 17th February 1872

Present Dr. Murney (President) in the chair, also Drs. McGee J.P., John Moore, James Moore, Charles, Fergus Brown, Walton Browne, McMeekin, Fagan, H. S. Purdon and Hill.

Dr. Fergus Brown then exhibited a child about 6 months old, presenting a curious malformation of the hands, both of which wanted the thumbs, and presented a turning upwards and inwards somewhat similar to talipes varus in the foot.

The general opinion was that it was inadvisable to interfere by any operative measures.

Dr. John Moore then give an account of a fractured base of skull which terminated fatally, and in which on P.M. examination a fracture of the calvaria of oldstanding was discovered.

It appeared that the man during life was particularly susceptible to the influence of drink, becoming at times quite maniacal—the fits however easily passed off under the influence of opiates.

A ballot was then taken for two members of Council when Dr. J. Walton Browne and Dr. Charles were duly elected.

Proposed by Dr. Hill and seconded by Dr. William McGee that Churchill's Medical Directory for 1872 be added to the library.

Notice was given that it would be proposed at next meeting that the Medical Register be added to the library.

Henry Murney M.D., President

2nd March 1872.

Ulster Medical Society 9th Meeting 2nd March

Present, Dr. Murney President in the chair, Drs. Cuming, Fergus Brown, Spedding, McCrea, Charles, Gribbin, Murray, Fagan, David Johnston, Stewart, James Moore, H. Johnston and Hill.

Ulster Medical Society
Session 1871–1872
President Henry Murney

The minutes of former meeting having been read and confirmed, Dr. Cuming proceeded to relate the particulars of a case of aneurism of aorta extending into abdomen which caused death by rupturing into left pleura.

In the absence of Dr. Browne, the President then related the case of a man æt 58 who fell from a height on the 2nd February and who died on the 25th after having suffered from symptoms of pyæmia.

On post-mortem examination a fissure was discovered across the right parietal bone, and corresponding with the fissure the brain surface presented an erosion covered with pus.

On cutting up the brain no abscesses were discovered. The other parts of the body were not examined.

Dr. James Moore then related the particulars of a case of scrofulous disease of knee joint in which he performed amputation of the thigh by a modification of the circular operation.

It was moved and seconded that the “Medical Register” for this year be added to the library.

It was moved by Professor Cuming and seconded by Dr. Gribbin and unanimously resolved that those periodicals which were incomplete through some of the posts having gone astray be completed.

Dr. McCrea then read the report of the Fee Committee, and as the time of the meeting has expired the discussion thereon was postponed until next day of meeting.

Henry Murney, President

16th March 1872

Present, Dr. Murney (President in the chair), Drs. Stewart, William McGee, Charles, Gribbin, Walton Browne, Spedding, Fergus Brown, Murray, John Moore, James Moore, McCrea, D. Johnston and Hill.

The President related the particulars of a case of injury requiring amputation of shoulder joint to which he had referred on 6th January.¹ For many weeks he continued to do well.

On the 7th of February the bed was raised and on the 9th he was permitted to get up. He was also up on the 10th. The ligatures, with one exception and that a small one, had come away.

At 3 p.m. on 11th got a message that hæmorrhage had taken place and on visiting him at once it was found he has lost about 2 ounces of blood although he was collapsed but that might be consequent from the fright. Ice was applied and rest enforced.

From 11th February till 4th March a watcher was continually with him.

On 23rd February—till which time the man ate and slept well—at 4:30 a.m. hæmorrhage again occurred to the extent of 6 ounces. At 9:30 a.m. after consultation

it was resolved to postpone operation measures till the bleeding should lessen which it did on the same day.

On the 27th he had a rigor. Also on 28th and 29th and 2nd March. Hæmorrhage again occurred and a rigor in the afternoon 3rd March 2 p.m. Slight hæmorrhage evening also. Also a recurrence on the fourth and he died same evening. On P.M. examination no clot was found.

The rest of the time was taken up with the consideration of the report of the Fee Committee which was adjourned till next meeting.

Henry Murney M.D., President
13 April 1872

Ulster Medical Society 13th April 1872

Present, Dr. Murney (President) in the chair, Drs. Stewart, Wales, Gribbin, Fergus Brown, McMeekin, Cuming, Walton Browne, Charles, McKeown, McCrea, John Moore and Hill

The minutes of former meeting having been read and confirmed it was moved by Dr. Wales seconded by Dr. Murney and resolved that a copy of the resolution of 20th April 1848 with the addition of the words “one guinea” be drafted out and circulated among the members of the profession for signature and approval.

A ballot having been taken for Dr. William Aickin he was unanimously elected a member of the Society.

The consideration of the report of the Fee Committee having been concluded the President proposed that the tariff be printed and laid before the Society at its next meeting.

Dr. McKeown then exhibited some patients on whom he had operated for various degrees and varieties of convergent squint and made remarks thereon.

In consequence of the amount of business to be transacted it was resolved to hold an extra meeting on Saturday the 20th inst.

Henry Murney M.D., President
20th April 1872

Ulster Medical Society 20th April

Present, Dr. Murney, President, in the chair, Drs. Stewart, Wales, John Moore, Gribbin, Spedding, H. S. Purdon, Charles, McMeekin, McCrea and Hill.

The minutes of former meeting having been read and confirmed, Dr. Charles proceeded to exhibit the following specimens viz.

- 1 Intracapsular fracture of neck of femur, and ossification of tendon of iliocostalis and psoas muscles of opposite side.
- 2 Malacosteon.
- 3 Chronic rheumatic arthritis of neck and hip joints
- 4 Fracture of tibia and fibula
- 5 Colloid cancer of stomach.
- 6 Tubercular peritonitis.

¹ [See page 1147.]

He gave a description of each, but as all the specimens have been obtained in the dissecting room he could not give the history of any of them.

The specimens themselves were exceedingly interesting and the President in the name of the Society thanked Dr. Charles for bringing them forward.

Henry Murney M.D., President
27th April 1872

Ulster Medical Society Concluding Meeting of Session 27th April 1872

Dr. Murney, President, in the chair, also Drs. Stewart, Wales, John Moore, Spedding, David Johnston, Fergus Brown, Walton Browne and Hill.

The minutes of former meeting having been read and confirmed, Dr. Johnston exhibited a subclavian artery taken from a man who had died of hæmorrhage 10 days after amputation at the shoulder joint on account of injury. The examination of the vessel showed that the hæmorrhage had not come from the main vessel but probably from a comparatively small branch which had been cut very close to the trunk.

He then exhibited a fracture of the spine which had occurred by a man falling off a house top. On admission to hospital though the nature of the injury was quite evident he did not present all the signs of grave spinal injury yet he only lived 36 hours.

John Moore also exhibited an enlarged heart, a hepatized lung, carcinoma of uterus and diseased kidneys but as the time was limited no discussion was given.

Doctor Wales then read a paper on positional pulmonary crepitus in which he described a fine crepitus like that of pneumonia heard on inspiration only and only in certain positions of the body. Having noticed this in several instances, and that it never led to serious consequences, and having been so frequently puzzled with it, he brought the subject under the notice of the Society in 1869–70.¹

He stated that his further experience only confirmed his former opinion that we frequently meet with pulmonic crepitus in practice which was attributed to pneumonia, limited no doubt, but treated as such; that if the patient's position had been altered and he was again examined the crepitus would be found to have disappeared but on resuming the former position it could again be heard.

He had not altogether made up his mind as to the theory of the phenomenon but it was no doubt interesting.

As the subject appeared to be altogether new to the members it was not discussed but all promised to be observant so that they might express an opinion should Dr. Wales bring up the subject at a future meeting.

The President then in a few words thanked the members for their attendance during the session and said that the next meeting will be held in November for the election of officer-bearers but that if anything of moment should occur in the meantime, he would summon an extraordinary meeting.

Henry Murney, M.D., President

Special Meeting called by circular held 14th August 1872 to consider the propriety of asking the British Medical Association to hold its Annual Meeting in August 1873 in Belfast.

Present, Dr. Murney President in the chair, Drs. Pirrie, Dill, M'Crea, John Moore, Walton Browne, Cuming, Stewart and Hill.

Moved by Dr. Dill seconded by Dr. Pirrie that thanks are due to the President for calling the meeting.

Moved by Dr. Pirrie that the Association be invited to meet be raised, seconded by Dr. M'Crea—negated by 5 to 4.

Annual meeting 1872

Held upon the 2nd November 1872

Dr. Stewart in the chair, Drs. John Moore, W. McGee, Spedding, J. J. Charles, Fagan and J. W. Browne.

The report of Annual Meeting of 1871 was read and adopted.

¹ [Occasion not identified.]

Ulster Medical Society
Session 1872–1873
President Henry Martyn Johnston

ULSTER MEDICAL SOCIETY

SESSION 1872–73

OFFICE-BEARERS
FOR THE SESSION 1872–73

President:

H. M. JOHNSTON, L.R.C.S.I.

Ex-President:

HENRY MURNEY, M.D., J.P.

Vice-Presidents:

J. W. T. SMITH, M.D. and ROBERT STEWART, M.D.

Members of Council:

J. W. BROWNE, M.D.	JOHN J. CHARLES, M.D.
W. A. M'KEOWN, M.D.	PROFESSOR CUMING, M.D.
H. S. PURDON, M.D.	B. SPEDDING, L.R.C.P. S. Ed.

Treasurer:

JOHN FAGAN, L.K.Q.C.P.

Secretary:

JOHN MOORE, M.D.

LIST OF MEMBERS, 1872–73.

Aickin, Wm., M.D., M.R.C.S.Eng.
Andrews, T., M.D., L.R.C.S.I., F.R.S.

Ball, T., L.R.C.P. Edin., L.A.H.
Barnett, R, M.D., M.R.C.S.Eng.
Beck, J. W., M.D., M.Ch., L.A.H.
Beck, F., L.R.C.P.&S.Edin., L.A.H.
Bolton, Reuben, M.D., L.A.H.
Browne, Sam., R.N., L.K.Q.C.P.I., M.R.C.S.Eng.
Browne, J. W., M.D., M.R.C.S.Eng.

Cantrell, T., L.A.H.
Charles, J. J., M.D., L.R.C.S. Edin.
Core, Wm., M.D., L.R.C.S. Edin.
Corry, T., M.D., M.R.C.S.Eng.
Croker, S., M.D., F.R.C.S.I.
Cuming, James, M.D.

Dill, R. F., M.D., M.R.C.S.Eng.
Drennan, J. S., M.D., L.R.C.S.I.

Fagan, J., L.K.Q.C.P.I., L.R.C.S.I.
Ferguson, H. S., M.D., M.R.C.S.Eng.
Filson, A., M.D., M.Ch.

Garde, T. W., L.R.C.P.&S.Ed., L.A.H.
Gordon, A., M.D., M.R.C.S.
Grattan, T., L.A.H.

Wales, G. F., M.D.
Wheeler, T., M.D., L.R.C.S.I.
Whitaker, H., M.D., M.R.C.S.Eng.

The First Meeting of the Society was held in the Library on Saturday 11th November 1872.

The Chair was occupied by the President, H. M. Johnston, L.R.C.S.I., who briefly thanked the Members of the Society for the honour they had done him by electing him President for the ensuing year; he referred to the improved state of the Society, as

marked by the increasing numbers attending its meetings, and the interesting Papers which had been read at them, during the past two years, under the Presidency of Drs. Smith and Murney.

He promised to do all in his power to maintain, and if possible to still further advance, the interests of the Society, as he had been long connected with it, and his interest in its prosperity had not diminished.

Members present Drs. Stewart, Murney, Smith, H. S. Purdon, McKeown, J. W. Browne, John Moore, Charles, Messrs. B. Smyth, Spedding, F. Brown and Gribbin.

The President then read notes of a case of a patient suffering from enlarged prostate gland and retention of urine and also exhibited the bladder and the enlarged gland.

Dr. Charles stated that from his observations in the dissecting room that he did not consider enlargement of the prostate to exist to such a large extent as some authors represented it, and he also said that the specimen before the Society was the largest he had ever seen. Dr. Murney also stated that it was his opinion also that enlargement of the prostate in men advanced in life was not so widespread as was commonly supposed.

The President next exhibited a specimen of stricture of the œsophagus causing ulceration of the aorta and causing death by hæmorrhage. He stated that six cases of this disease had been under his care within the last few years.

Dr. Murney stated that the question of gastrotomy had recently been raised in the treatment of cases of impassable stricture of the gullet.

Dr. John Moore said that he had seen a patient in St Thomas' Hospital in whom Mr. Le Gros Clarke had performed this operation and was afterwards present at the post-mortem examination. From what he had seen he was not favourably impressed with the operation and would not be inclined to repeat it.

He said he recently had a case under his care where the patient has been from Tuesday to Saturday unable to swallow anything. He succeeded in passing a very small catheter into the stomach and feeding him for some time after which he could swallow and left the hospital greatly improved.

The Second Meeting of the Society was held in its Library on Saturday 30th November.

The President in the chair. Members present Drs. William McGee, Stewart, Smith, McCrea, Charles, J. W. Browne, Croker, David Johnston, Messrs. McConnell, Spedding, F. Brown and assist. Surgeon Johnston 78th Highlanders.

Dr. David Johnson introduced a patient suffering from occasional attacks of dyspnœa and stridulous breathing. There was some swelling over right sternoclavicular articulation. No bruit could be heard, but

several members considered the case to be one of the thoracic aneurism.

Dr. John Moore read the following Paper on Gun-shot and other Wounds: On Sunday, the 18th of August, J. M_, aged 17 years, P. C_, aged 15 years, J. S_, aged 21 years, and P. D_, aged 10 years, were admitted into the Belfast General Hospital under my care. The first three were suffering from gun-shot wounds of the thigh, M_ received a ball about the middle of the thigh, S_ another a little above the patella, and G_ one at the junction of the middle and lower third, the latter passing transversely across the limb from without inwards. The two former were wounded in front, the point of exit in S's case being the centre of the popliteal space. In the three cases the balls passed right through the limbs without lodging, and must have impinged very closely on the femora, as the balls had passed through the entire thickness of the limbs. The only points worthy of note in these cases were, first, that all the wounds inflicted being in the lower extremities, it is evident that the constabulary, who were the firing party in this case, were desirous of avoiding inflicting fatal injury, and aimed low. All these cases did well; there was no inflammation nor tumefaction following the wounds, nor any constitutional disturbance. The treatment consisted in rest, syringing the wound with carbolic acid lotion, and lint wet with the same lotion, laid on the wound. In the beginning of September the wounds had closed; the patients were allowed to move about, and a few days afterwards discharged.

With the lad, D_, however, it was otherwise. In his case, the bullet entered the right foot, just below the internal maleolus and passing through the astragalus and calcis, made its exit at the insertion of the tendo Achilles. As the ankle joint had escaped injury, and from the youth and healthy constitution of the lad, I determined to give a trial to conservative surgery, and to save, if possible, his foot. Nothing could be better than his progress for the first fortnight; the slight inflammation which followed was subsiding, and the suppuration which had been established was of a healthy character, when about this time, unfortunately, there was admitted a case of foul tertiary ulcer into the same ward; and from that time the character of the wound assumed a different aspect; it became unhealthy looking; inflammation spread up the limb, and abscesses formed, which when opened discharged putrid pus. He became irritable, his pulse rose to 140, and his appetite declined. It soon became evident that it would be impossible to save the limb. The next question was when to operate, and where to amputate. His then condition (September 3) was very unsatisfactory, and an erysipelatous blush extended above the knee, with threatening abscess of that joint. The sloughing state of the soft parts about the heel rendered it impossible to find covering at that joint, if

amputation there had been decided on. He was ordered all the nourishment he could take, with wine, quinine, and opium. On the 12th September his general condition had improved somewhat, and the inflammation around was diminished, so I amputated his leg at the junction of the upper and middle third by the usual method adopted here—skin flaps and circular incision through the muscle.

During the week after operation his condition was very shaky, he had slight rigors, and the knee joint still threatened to suppurate. In fact pyæmic symptoms manifested themselves. By careful attention to diet, by allaying irritation, with opiates, by a liberal allowance of stimulants, and especially by quinine, these symptoms subsided, and he was discharged on October 2nd with a good stump, having been 46 days in Hospital.

I am glad to be able to leave on record that this was the only limb lost during those disgraceful proceedings, which attracted to our town such an amount of unenviable notoriety; and that not a single death occurred in the General Hospital resulting from those riots.

S. J. W_, aged 20, was admitted on 20th September, he had received a gunshot wound in the back, the ball entering close by the posterior edge of the left scapula, and emerging under the middle of the clavicle of the same side, close by the sub-clavian artery. There was no chest complication, no emphysema, nor hæmoptysis. There was very little shock from the wound, and he recovered without an unfavourable symptom. The interesting point in this case was the curious track the ball must have taken, and the narrow escape he had for his life.

S. D_, a good-looking girl of 18, was admitted with a bullet wound of shoulder. She had been leaving, under compulsion, one district of the town, and seeking refuge in another, when she was met by a man who presented a gun at her. As she was within speaking distance, and not thinking that he really meant to shoot her, she said to him, half jestingly, "If you do now I'll tell," when the ruffian fired, the ball entering the shoulder at the posterior edge of the deltoid muscle; and, after grazing the humerus, glanced off without fracturing the bone, or entering the chest. This seemed to me to be the most diabolical of all the crimes which came to my knowledge as having occurred during that unhappy period. She too, made a good recovery, and has not suffered any permanent injury resulting from her wound.

Three cases of wounds from revolvers were admitted. In fact the first of the riot cases were two such admitted under Dr. Murray. The first one was that of a lad who was shot in the left forearm the ball striking and fracturing the ulna. The ball in this case could not be detected, and still remains in the arm; but the wound healed and the fracture united.

The second case was a bullet wound of left groin. It entered close by the saphenous opening, and taking an inward course, emerged at the fold of the perineum just marking the scrotum. He also was Dr. Murray's patient.

The third revolver wound was in the calf of right leg. He received his wound behind; the opening was very small, and I failed to touch the bullet with a probe; and I believe it still remains, without giving him any trouble.

One case was admitted in which a charge of large shot had been received over the head, face, and neck. One had crossed the track of the carotid vessels, another passed through the right cheek and through the tongue, lodging in the left gum. I extracted several others from the forehead and scalp.

Three cases of stabs were treated.

H. G. A_, residing in M_, had served in the army, and fought all through the Crimean War, was passing down North Street, which was in a crowded and disturbed state at the time, when a charge of mounted constabulary came down; and while endeavouring to make his way into a door, received a sword thrust which transfixed the axilla, entering through the latissimus dorsi, and coming out at the edge of the pectoral muscle. He was carried to the Hospital in a fainting state, and was in complete collapse when he arrived. His clothes were saturated with blood; and while he was being placed in bed, and his clothes removed, his bowels became relaxed, and he appeared moribund. He seemed as if he had bled to death.

I placed my thumb firmly in the wound, and by the free administration of stimulants with warm milk and hot water pans placed around him, he returned to consciousness, but so bloodless and weak was his condition that no operative interference could be attempted. Under those circumstances I plugged the wound with pledgets of lint, as firmly as possible, placed a bandage tightly round the limb, which restrained all hæmorrhage; a tourniquet was put around the shoulder, and a student was placed in charge of the case, and arrangements made to place a ligature on the vessel should further bleeding occur. A good opiate procured him a quiet night, and I found in the morning that there had been no return of the bleeding.

On removing the plugging on the second morning, about thirty-six hours after his admission, no blood followed, and complete blocking up of the vessel of the limb seemed to have taken place. There was no pulsation in the axillary or brachial artery, there was some degree of numbness of the arm, and its temperature was lower than the other limb.

Considerable inflammation followed, an erysipelatous blush spread over the upper arm, and an inflamed cord of lymphatics extended from the elbow

up to the axilla. Suppuration became established, and a large quantity of pus escaped from the wound. Several of the glands in the axilla suppurated, and I opened them. Notwithstanding so much local mischief, there was little constitutional disturbance. He took food, and slept well. The inflammation of the arm gradually subsided, the purulent discharge ceased, and the wound closed. He was discharged with good use of his arm, and is now following the laborious occupation of a pavior.

William M_ was admitted with a circular spot of blood, about the size of the palm of hand, on right side of vest, with a triangular puncture in the centre, which on examination was found to pass through the seventh intercostal space on right side of sternum. It was a bayonet wound, but not deep; he was more frightened than hurt, and was discharged in a few days with the wound healed.

Patrick R_ when admitted was found suffering from a penetrating wound of abdomen. It had been inflicted by a dagger, and penetrated on the outside of the right rectus muscle, extending about two inches on a level with the umbilicus. The finger passed into the abdominal cavity, but the bowels seemed to have escaped injury. The edges of the wound were brought carefully together and covered with collodion. On the day after admission the stomach became irritable, there was some abdominal tenderness, these symptoms increased, the pulse became more frequent, the abdomen became tympanitic. For several days his state was most critical. The treatment consisted of opium, ice with turpentine fomentations, and under it the severity of the symptoms gradually subsided, and he was discharged well.

Matthew L_ when admitted presented a sad aspect, he had been unmercifully beaten about the head and face, his countenance was so disfigured that it would have been impossible to have recognized him. The bones of the face felt as if they had been separated from one another, and the left superior maxillary bone was fractured, as was the left horizontal ramus of the lower jaw. Notwithstanding the severity of the injuries inflicted he made a rapid and good recovery, with but little deformity.

Ten other cases less severe were admitted into Hospital. They consisted principally of scalp wounds, fractured ribs, and contusions.

One hundred and twenty cases were treated by the House Surgeon and resident staff, none of which call for special notice.

Dr. James Smith exhibited a specimen of thoracic aneurism and read the notes of the case.

Dr. Torrens was proposed as a member of the Society by Dr. John Moore.

The Third Meeting of the Society was held in its Library on Saturday 14th December 1872 at 4 o'clock

The President in the chair. Members present Drs. Stewart, H. S. Purdon, J. W. Browne, J. W. T. Smith, Charles, Croker, Porter, John Moore and Wales, Messrs. McMeekin, Spedding and Gribbin. Assist. Surgeon Johnston 78th Highlanders was also present.

Drs. Torrens and Bolton were elected members of the Society and Dr. Filson of Portaferry and Dr. Tyrrell of Banbridge also.

Dr. Porter introduced a patient with great deformity of chest. There was considerable projection of sternum with corresponding falling-in of the costal cartilages. The boy was healthy and did not suffer except from the deformity which it caused. Some of the members were of opinion that a considerable improvement might be affected by a proper mechanical apparatus.

Dr. McMeekin read a most interesting paper on a case of induced labour in a patient who had on two previous confinements been delivered by craniotomy. In this case both mother and child done well.

This operation, formerly vague and uncertain in its results, has now assumed a definiteness and precision that bring it completely under the control of the physician.
